## Digital Resources for Students

Your new textbook provides 12-month access to digital resources that may include VideoNotes (step-by-step video tutorials on programming concepts), source code, web chapters, quizzes, and more. Refer to the preface in the textbook for a detailed list of resources.

Follow the instructions below to register for the Companion Website for Tony Gaddis' Starting Out with C++ from Control Structures through Objects, Ninth Edition, Global Edition.

1. Go to www.pearsonglobaleditions.com/gaddis
2. Enter the title of your textbook or browse by author name.
3. Click Companion Website.
4. Click Register and follow the on-screen instructions to create a login name and password.

## ISSGDS-SPADA-BAUTH-SKEAN-FIERI-BALES

Use the login name and password you created during registration to start using the online resources that accompany your textbook.

## IMPORTANT:

This prepaid subscription does not include access to MyProgrammingLab, which is available at www.myprogramminglab.com for purchase.

This access code can only be used once. This subscription is valid for 12 months upon activation and is not transferable.

For technical support go to https://support.pearson.com/getsupport

## Contents at a Glance

Preface ..... 17
CHAPTER 1 Introduction to Computers and Programming ..... 33
CHAPTER 2 Introduction to C++ ..... 59
CHAPTER 3 Expressions and Interactivity ..... 117
CHAPTER 4 Making Decisions ..... 183
CHAPTER 5 Loops and Files ..... 263
CHAPTER 6 Functions ..... 337
CHAPTER 7 Arrays and Vectors ..... 413
CHAPTER 8 Searching and Sorting Arrays ..... 495
CHAPTER 9 Pointers ..... 535
CHAPTER 10 Characters, C-Strings, and More about the string Class ..... 559
CHAPTER 11 Structured Data ..... 645
CHAPTER 12 Advanced File Operations ..... 697
CHAPTER 13 Introduction to Classes ..... 751
CHAPTER 14 More about Classes ..... 849
CHAPTER 15 Inheritance, Polymorphism, and Virtual Functions ..... 939
CHAPTER 16 Exceptions and Templates ..... 1021
CHAPTER 17 The Standard Template Library ..... 1061
CHAPTER 18 Linked Lists ..... 1155
CHAPTER 19 Stacks and Queues ..... 1197
CHAPTER 20 Recursion ..... 1255
CHAPTER 21 Binary Trees ..... 1289
Appendix A: The ASCII Character Set ..... 1319
Appendix B: Operator Precedence and Associativity ..... 1321
Quick References ..... 1323
Index ..... 1325
Credit ..... 1343
Online The following appendices are available at www.pearsonglobaleditions.com/gaddis.
Appendix C: Introduction to Flowcharting
Appendix D: Using UML in Class Design
Appendix E: Namespaces
Appendix F: Passing Command Line Arguments
Appendix G: Binary Numbers and Bitwise Operations
Appendix H: STL Algorithms
Appendix I: Multi-Source File Programs
Appendix J: Stream Member Functions for Formatting
Appendix K: Unions
Appendix L: Answers to Checkpoints
Appendix M: Answers to Odd Numbered Review Questions
Case Study 1: String Manipulation
Case Study 2: High Adventure Travel Agency-Part 1
Case Study 3: Loan Amortization
Case Study 4: Creating a String Class
Case Study 5: High Adventure Travel Agency-Part 2
Case Study 6: High Adventure Travel Agency—Part 3
Case Study 7: Intersection of Sets
Case Study 8: Sales Commission

## Contents

## Preface 17

## CHAPTER 1 Introduction to Computers and Programming <br> 33

1.1 Why Program? ..... 33
1.2 Computer Systems: Hardware and Software ..... 34
1.3 Programs and Programming Languages ..... 40
1.4 What Is a Program Made of? ..... 46
1.5 Input, Processing, and Output ..... 49
1.6 The Programming Process ..... 50
1.7 Procedural and Object-Oriented Programming ..... 54
Review Questions and Exercises ..... 56
CHAPTER 2 Introduction to C++ ..... 59
2.1 The Parts of a C++ Program ..... 59
2.2 The cout Object ..... 63
2.3 The \#include Directive ..... 68
2.4 Variables, Literals, and Assignment Statements ..... 70
2.5 Identifiers ..... 74
2.6 Integer Data Types ..... 75
2.7 The char Data Type ..... 81
2.8 The C++ string Class ..... 85
2.9 Floating-Point Data Types ..... 87
2.10 The bool Data Type ..... 90
2.11 Determining the Size of a Data Type ..... 91
2.12 More about Variable Assignments and Initialization ..... 92
2.13 Scope ..... 94
2.14 Arithmetic Operators ..... 95
2.15 Comments ..... 103
2.16 Named Constants ..... 105
2.17 Programming Style ..... 107
Review Questions and Exercises ..... 109
Programming Challenges ..... 113
CHAPTER 3 Expressions and Interactivity ..... 117
3.1 The cin Object ..... 117
3.2 Mathematical Expressions ..... 123
3.3 When You Mix Apples and Oranges: Type Conversion ..... 132
3.4 Overflow and Underflow ..... 134
3.5 Type Casting ..... 135
3.6 Multiple Assignment and Combined Assignment ..... 138
3.7 Formatting Output ..... 142
3.8 Working with Characters and string Objects ..... 152
3.9 More Mathematical Library Functions ..... 158
3.10 Focus on Debugging: Hand Tracing a Program ..... 164
3.11 Focus on Problem Solving: A Case Study ..... 166
Review Questions and Exercises ..... 170
Programming Challenges ..... 176
CHAPTER 4 Making Decisions ..... 183
4.1 Relational Operators ..... 183
4.2 The if Statement ..... 188
4.3 Expanding the if Statement ..... 196
4.4 The if/else Statement ..... 200
4.5 Nested if Statements ..... 203
4.6 The if/else if Statement ..... 210
4.7 Flags ..... 215
4.8 Logical Operators ..... 216
4.9 Checking Numeric Ranges with Logical Operators ..... 223
4.10 Menus ..... 224
4.11 Focus on Software Engineering: Validating User Input ..... 227
4.12 Comparing Characters and Strings ..... 229
4.13 The Conditional Operator ..... 233
4.14 The switch Statement ..... 236
4.15 More about Blocks and Variable Scope ..... 245
Review Questions and Exercises ..... 248
Programming Challenges ..... 254
CHAPTER 5 Loops and Files ..... 263
5.1 The Increment and Decrement Operators ..... 263
5.2 Introduction to Loops: The while Loop ..... 268
5.3 Using the while Loop for Input Validation ..... 275
5.4 Counters ..... 277
5.5 The do-while Loop ..... 278
5.6 The for Loop ..... 283
5.7 Keeping a Running Total ..... 293
5.8 Sentinels ..... 296
5.9 Focus on Software Engineering: Deciding Which Loop to Use ..... 297
5.10 Nested Loops ..... 298
5.11 Using Files for Data Storage ..... 301
5.12 Optional Topics: Breaking and Continuing a Loop ..... 320
Review Questions and Exercises ..... 324
Programming Challenges ..... 329
CHAPTER 6 Functions ..... 337
6.1 Focus on Software Engineering: Modular Programming ..... 337
6.2 Defining and Calling Functions ..... 338
6.3 Function Prototypes ..... 347
6.4 Sending Data into a Function ..... 349
6.5 Passing Data by Value ..... 354
6.6 Focus on Software Engineering: Using Functions in a Menu-Driven Program ..... 356
6.7 The return Statement ..... 360
6.8 Returning a Value from a Function ..... 362
6.9 Returning a Boolean Value ..... 370
6.10 Local and Global Variables ..... 372
6.11 Static Local Variables ..... 380
6.12 Default Arguments ..... 383
6.13 Using Reference Variables as Parameters ..... 386
6.14 Overloading Functions ..... 392
6.15 The exit() Function ..... 396
6.16 Stubs and Drivers ..... 399
Review Questions and Exercises ..... 401
Programming Challenges ..... 404
CHAPTER 7 Arrays and Vectors ..... 413
7.1 Arrays Hold Multiple Values ..... 413
7.2 Accessing Array Elements ..... 415
7.3 No Bounds Checking in C++ ..... 427
7.4 The Range-Based for Loop ..... 430
7.5 Processing Array Contents ..... 434
7.6 Focus on Software Engineering: Using Parallel Arrays ..... 442
7.7 Arrays as Function Arguments ..... 445
7.8 Two-Dimensional Arrays ..... 456
7.9 Arrays with Three or More Dimensions ..... 463
7.10 Focus on Problem Solving and Program Design: A Case Study ..... 465
7.11 Introduction to the STL vector ..... 467
Review Questions and Exercises ..... 481
Programming Challenges ..... 486
CHAPTER 8 Searching and Sorting Arrays ..... 495
8.1 Focus on Software Engineering: Introduction to Search Algorithms ..... 495
8.2 Focus on Problem Solving and Program Design: A Case Study ..... 501
8.3 Focus on Software Engineering: Introduction to Sorting Algorithms ..... 508
8.4 Focus on Problem Solving and Program Design: A Case Study ..... 518
8.5 Sorting and Searching vectors ..... 527
Review Questions and Exercises ..... 530
Programming Challenges ..... 531
CHAPTER 9 Pointers ..... 535
9.1 Getting the Address of a Variable ..... 535
9.2 Pointer Variables ..... 537
9.3 The Relationship between Arrays and Pointers ..... 544
9.4 Pointer Arithmetic ..... 548
9.5 Initializing Pointers ..... 550
9.6 Comparing Pointers ..... 551
9.7 Pointers as Function Parameters ..... 553
9.8 Dynamic Memory Allocation ..... 562
9.9 Returning Pointers from Functions ..... 566
9.10 Using Smart Pointers to Avoid Memory Leaks ..... 573
9.11 Focus on Problem Solving and Program Design: A Case Study ..... 576
Review Questions and Exercises ..... 582
Programming Challenges ..... 585
CHAPTER 10 Characters, C-Strings, and More about the string Class ..... 589
10.1 Character Testing ..... 589
10.2 Character Case Conversion ..... 593
10.3 C-Strings ..... 596
10.4 Library Functions for Working with C-Strings ..... 600
10.5 String/Numeric Conversion Functions ..... 611
10.6 Focus on Software Engineering: Writing Your Own C-String-Handling Functions ..... 617
10.7 More about the C++ string Class ..... 623
10.8 Focus on Problem Solving and Program Design: A Case Study ..... 635
Review Questions and Exercises ..... 636
Programming Challenges ..... 639
CHAPTER 11 Structured Data ..... 645
11.1 Abstract Data Types ..... 645
11.2 Structures ..... 647
11.3 Accessing Structure Members ..... 650
11.4 Initializing a Structure ..... 654
11.5 Arrays of Structures ..... 657
11.6 Focus on Software Engineering: Nested Structures ..... 659
11.7 Structures as Function Arguments ..... 663
11.8 Returning a Structure from a Function ..... 666
11.9 Pointers to Structures ..... 669
11.10 Focus on Software Engineering: When to Use ., When to Use ->, and When to Use * ..... 672
11.11 Enumerated Data Types ..... 674
Review Questions and Exercises ..... 685
Programming Challenges ..... 691
CHAPTER 12 Advanced File Operations ..... 697
12.1 File Operations ..... 697
12.2 File Output Formatting ..... 703
12.3 Passing File Stream Objects to Functions ..... 705
12.4 More Detailed Error Testing ..... 707
12.5 Member Functions for Reading and Writing Files ..... 710
12.6 Focus on Software Engineering: Working with Multiple Files ..... 718
12.7 Binary Files ..... 720
12.8 Creating Records with Structures ..... 725
12.9 Random-Access Files ..... 729
12.10 Opening a File for Both Input and Output ..... 737
Review Questions and Exercises ..... 742
Programming Challenges ..... 745
CHAPTER 13 Introduction to Classes ..... 751
13.1 Procedural and Object-Oriented Programming ..... 751
13.2 Introduction to Classes ..... 758
13.3 Defining an Instance of a Class ..... 763
13.4 Why Have Private Members? ..... 776
13.5 Focus on Software Engineering: Separating Class Specification from Implementation ..... 777
13.6 Inline Member Functions ..... 783
13.7 Constructors ..... 786
13.8 Passing Arguments to Constructors ..... 791
13.9 Destructors ..... 799
13.10 Overloading Constructors ..... 803
13.11 Private Member Functions ..... 807
13.12 Arrays of Objects ..... 809
13.13 Focus on Problem Solving and Program Design: An OOP Case Study ..... 813
13.14 Focus on Object-Oriented Programming: Simulating Dice with Objects ..... 820
13.15 Focus on Object-Oriented Design: The Unified Modeling Language (UML) ..... 824
13.16 Focus on Object-Oriented Design: Finding the Classes and Their Responsibilities ..... 826
Review Questions and Exercises ..... 835
Programming Challenges ..... 840
CHAPTER 14 More about Classes ..... 849
14.1 Instance and Static Members ..... 849
14.2 Friends of Classes ..... 857
14.3 Memberwise Assignment ..... 862
14.4 Copy Constructors ..... 863
14.5 Operator Overloading ..... 869
14.6 Object Conversion ..... 896
14.7 Aggregation ..... 898
14.8 Focus on Object-Oriented Design: Class Collaborations ..... 903
14.9 Focus on Object-Oriented Programming: Simulating the Game of Cho-Han ..... 908
14.10 Rvalue References and Move Semantics ..... 918
Review Questions and Exercises ..... 927
Programming Challenges ..... 932
CHAPTER 15 Inheritance, Polymorphism, and Virtual Functions ..... 939
15.1 What Is Inheritance? ..... 939
15.2 Protected Members and Class Access ..... 948
15.3 Constructors and Destructors in Base and Derived Classes ..... 954
15.4 Redefining Base Class Functions ..... 968
15.5 Class Hierarchies ..... 973
15.6 Polymorphism and Virtual Member Functions ..... 979
15.7 Abstract Base Classes and Pure Virtual Functions ..... 995
15.8 Multiple Inheritance ..... 1002
Review Questions and Exercises 1009
Programming Challenges ..... 1013
CHAPTER 16 Exceptions and Templates ..... 1021
16.1 Exceptions ..... 1021
16.2 Function Templates ..... 1040
16.3 Focus on Software Engineering: Where to Start When Defining Templates ..... 1046
16.4 Class Templates ..... 1046
Review Questions and Exercises ..... 1056
Programming Challenges ..... 1058
CHAPTER 17 The Standard Template Library ..... 1061
17.1 Introduction to the Standard Template Library ..... 1061
17.2 STL Container and Iterator Fundamentals ..... 1061
17.3 The vector Class ..... 1072
17.4 The map, multimap, and unordered_map Classes ..... 1086
17.5 The set, multiset, and unordered_set Classes ..... 1111
17.6 Algorithms ..... 1118
17.7 Introduction to Function Objects and Lambda Expressions ..... 1139
Review Questions and Exercises ..... 1146
Programming Challenges ..... 1150
CHAPTER 18 Linked Lists ..... 1155
18.1 Introduction to the Linked List ADT ..... 1155
18.2 Linked List Operations ..... 1157
18.3 A Linked List Template ..... 1173
18.4 Variations of the Linked List ..... 1185
18.5 The STL list and forward_list Containers ..... 1186
Review Questions and Exercises ..... 1190
Programming Challenges ..... 1193
CHAPTER 19 Stacks and Queues ..... 1197
19.1 Introduction to the Stack ADT ..... 1197
19.2 Dynamic Stacks ..... 1214
19.3 The STL stack Container ..... 1225
19.4 Introduction to the Queue ADT ..... 1227
19.5 Dynamic Queues ..... 1239
19.6 The STL deque and queue Containers ..... 1246
Review Questions and Exercises ..... 1249
Programming Challenges ..... 1251
CHAPTER 20 Recursion ..... 1255
20.1 Introduction to Recursion ..... 1255
20.2 Solving Problems with Recursion ..... 1259
20.3 Focus on Problem Solving and Program Design: The Recursive gad Function ..... 1267
20.4 Focus on Problem Solving and Program Design: Solving Recursively Defined Problems ..... 1268
20.5 Focus on Problem Solving and Program Design: Recursive Linked List ..... 1269Operations
20.6 Focus on Problem Solving and Program Design: A Recursive Binary Search Function ..... 1273
20.7 The Towers of Hanoi ..... 1275
20.8 Focus on Problem Solving and Program Design: The QuickSort Algorithm ..... 1278
20.9 Exhaustive Algorithms ..... 1282
20.10 Focus on Software Engineering: Recursion versus Iteration ..... 1285
Review Questions and Exercises ..... 1285
Programming Challenges ..... 1287
CHAPTER 21 Binary Trees ..... 1289
21.1 Definition and Applications of Binary Trees ..... 1289
21.2 Binary Search Tree Operations ..... 1292
21.3 Template Considerations for Binary Search Trees ..... 1309
Review Questions and Exercises ..... 1315
Programming Challenges ..... 1316
Appendix A: The ASCII Character Set ..... 1319
Appendix B: Operator Precedence and Associativity ..... 1321
Quick References ..... 1323
Index ..... 1325
Credit ..... 1343

## Preface

Welcome to Starting Out with C++: From Control Structures through Objects, 9th edition. This book is intended for use in a two-semester C++ programming sequence, or an accelerated one-semester course. Students new to programming, as well as those with prior course work in other languages, will find this text beneficial. The fundamentals of programming are covered for the novice, while the details, pitfalls, and nuances of the C++ language are explored in depth for both the beginner and more experienced student. The book is written with clear, easy-to-understand language, and it covers all the necessary topics for an introductory programming course. This text is rich in example programs that are concise, practical, and real-world oriented, ensuring that the student not only learns how to implement the features and constructs of $\mathrm{C}++$, but why and when to use them.

## Changes in the Ninth Edition

This book's pedagogy, organization, and clear writing style remain the same as in the previous edition. Many improvements and updates have been made, which are summarized here:

- The material on the Standard Template Library (STL) has been completely rewritten and expanded into its own chapter. Previously, Chapter 16 covered exceptions, templates, and gave brief coverage to the STL. In this edition, Chapter 16 covers exceptions and templates, and Chapter 17 is a new chapter dedicated to the STL. The new chapter covers the following topics:
- The array and vector classes
- The various types of iterators
- Emplacement versus insertion
- The map, multimap, and unordered_map Classes
- The set, multiset, and unordered_set Classes
- Sorting and searching algorithms
- Permutation algorithms
- Set algorithms
- Using function pointers with STL algorithms
- Function objects, or functors
- Lambda expressions
- Chapter 2 now includes a discussion of alternative forms of variable initialization, including functional notation, and brace notation (also known as uniform initialization).
- Chapter 3 now mentions the round function, introduced in C++ 11 .
- Chapter 7 now introduces array initialization much earlier.
- In Chapter 8, the bubble sort algorithm has been rewritten and improved.
- A new example of sorting and searching a vector of strings has been added to Chapter 8.
- In Chapter 9, the section on smart pointers now gives an overview of shared_ptrs and weak_ptrs, in addition to the existing coverage of unique_ptrs.
- In Chapter 10, a new In the Spotlight section on string tokenizing has been added.
- Chapter 10 now covers the string-to-number conversion functions that were introduced in C++ 11 .
- The material on unions that previously appeared in Chapter 11 has been moved to Appendix K, available on the book's companion Website.
- Chapter 13 has new sections covering:
- Member initialization lists.
- In-place initialization.
- Constructor delegation.
- Several new topics were added to Chapter 14, including:
- Rvalue references and move semantics.
- Checking for self-assignment when overloading the $=$ operator.
- Using member initialization lists in aggregate classes.
- Chapter 15 includes a new section on constructor inheritance.
- Several new programming problems have been added throughout the book.

## Organization of the Text

This text teaches C++ in a step-by-step fashion. Each chapter covers a major set of topics and builds knowledge as the student progresses through the book. Although the chapters can be easily taught in their existing sequence, some flexibility is provided. The diagram shown in Figure P-1 suggests possible sequences of instruction.

Chapter 1 covers fundamental hardware, software, and programming concepts. You may choose to skip this chapter if the class is already familiar with those topics. Chapters 2 through 7 cover basic C++ syntax, data types, expressions, selection structures, repetition structures, functions, and arrays. Each of these chapters builds on the previous chapter and should be covered in the order presented.
After Chapter 7 has been covered, you may proceed to Chapter 8 , or jump to Chapter 9.
After Chapter 9 has been covered, Chapter 10, 11, 12, or 13 may be covered. (If you jump to Chapter 12 at this point, you will need to postpone Sections $12.8,12.9$, and 12.10 until Chapter 11 has been covered.) After Chapter 13, you may cover Chapters 14 through 18 in sequence. Next, you can proceed to either Chapter 19 or Chapter 20. Finally, Chapter 21 may be covered.

This text's approach starts with a firm foundation in structured, procedural programming before delving fully into object-oriented programming and advanced data structures.

Figure P-1 Chapter dependency chart

## Brief Overview of Each Chapter

## Chapter 1: Introduction to Computers and Programming

This chapter provides an introduction to the field of computer science and covers the fundamentals of programming, problem solving, and software design. The components of programs, such as key words, variables, operators, and punctuation, are covered. The tools of the trade, such as pseudocode, flow charts, and hierarchy charts, are also presented.

## Chapter 2: Introduction to C++

This chapter gets the student started in C++ by introducing data types, identifiers, variable declarations, constants, comments, program output, simple arithmetic operations, and C-strings. Programming style conventions are introduced and good programming style is modeled here, as it is throughout the text.

## Chapter 3: Expressions and Interactivity

In this chapter, the student learns to write programs that input and handle numeric, character, and string data. The use of arithmetic operators and the creation of mathematical expressions are covered in greater detail, with emphasis on operator precedence. Debugging is introduced, with a section on hand tracing a program. Sections are also included on simple output formatting, on data type conversion and type casting, and on using library functions that work with numbers.

## Chapter 4: Making Decisions

Here, the student learns about relational operators, relational expressions, and how to control the flow of a program with the if, if/else, and if/else if statements. The conditional operator and the switch statement are also covered. Crucial applications of these constructs are covered, such as menu-driven programs and the validation of input.

## Chapter 5: Loops and Files

This chapter covers repetition control structures. The while loop, do-while loop, and for loop are taught, along with common uses for these devices. Counters, accumulators, running totals, sentinels, and other application-related topics are discussed. Sequential file I/O is also introduced. The student learns to read and write text files, and use loops to process the data in a file.

## Chapter 6: Functions

In this chapter, the student learns how and why to modularize programs, using both void and value returning functions. Argument passing is covered, with emphasis on when arguments should be passed by value versus when they need to be passed by reference. Scope of variables is covered, and sections are provided on local versus global variables and on static local variables. Overloaded functions are also introduced and demonstrated.

## Chapter 7: Arrays and Vectors

In this chapter, the student learns to create and work with single and multi-dimensional arrays. Many examples of array processing are provided including examples illustrating how to find the sum, average, highest, and lowest values in an array, and how to sum the rows, columns, and all elements of a two-dimensional array. Programming techniques using parallel arrays are also demonstrated, and the student is shown how to use a data file as an input source to populate an array. STL vectors are introduced and compared to arrays.

## Chapter 8: Searching and Sorting Arrays

Here, the student learns the basics of sorting arrays and searching for data stored in them. The chapter covers the Bubble Sort, Selection Sort, Linear Search, and Binary Search algorithms. There is also a section on sorting and searching STL vector objects.

## Chapter 9: Pointers

This chapter explains how to use pointers. Pointers are compared to and contrasted with reference variables. Other topics include pointer arithmetic, initialization of pointers, relational comparison of pointers, pointers and arrays, pointers and functions, dynamic memory allocation, and more.

## Chapter 10: Characters, C-Strings, and More about the string Class

This chapter discusses various ways to process text at a detailed level. Library functions for testing and manipulating characters are introduced. C-strings are discussed, and the technique of storing C -strings in char arrays is covered. An extensive discussion of the string class methods is also given.

## Chapter 11: Structured Data

The student is introduced to abstract data types and taught how to create them using structures, unions, and enumerated data types. Discussions and examples include using pointers to structures, passing structures to functions, and returning structures from functions.

## Chapter 12: Advanced File Operations

This chapter covers sequential access, random access, text, and binary files. The various modes for opening files are discussed, as well as the many methods for reading and writing file contents. Advanced output formatting is also covered.

## Chapter 13: Introduction to Classes

The student now shifts focus to the object-oriented paradigm. This chapter covers the fundamental concepts of classes. Member variables and functions are discussed. The student learns about private and public access specifications, and reasons to use each. The topics of constructors, overloaded constructors, and destructors are also presented. The chapter presents a section modeling classes with UML, and how to find the classes in a particular problem.

## Chapter 14: More about Classes

This chapter continues the study of classes. Static members, friends, memberwise assignment, and copy constructors are discussed. The chapter also includes in-depth sections on operator overloading, object conversion, and object aggregation. There is also a section on class collaborations and the use of CRC cards.

## Chapter 15: Inheritance, Polymorphism, and Virtual Functions

The study of classes continues in this chapter with the subjects of inheritance, polymorphism, and virtual member functions. The topics covered include base and derived class constructors and destructors, virtual member functions, base class pointers, static and dynamic binding, multiple inheritance, and class hierarchies.

## Chapter 16: Exceptions and Templates

The student learns to develop enhanced error trapping techniques using exceptions. Discussion then turns to function and class templates as a method for reusing code.

## Chapter 17: The Standard Template Library

This chapter discusses the containers, iterators, and algorithms in the Standard Template Library (STL). The specific containers covered are the array, vector, map, multimap, unordered_map, set, multiset, and unordered_set classes. The student then learns about sorting, searching, permutation, and set algorithms. The chapter concludes with a discussion of function objects (functors) and lambda functions.

## Chapter 18: Linked Lists

This chapter introduces concepts and techniques needed to work with lists. A linked list ADT is developed and the student is taught to code operations such as creating a linked list, appending a node, traversing the list, searching for a node, inserting a node, deleting a node, and destroying a list. A linked list class template is also demonstrated.

## Chapter 19: Stacks and Queues

In this chapter, the student learns to create and use static and dynamic stacks and queues. The operations of stacks and queues are defined, and templates for each ADT are demonstrated.

## Chapter 20: Recursion

This chapter discusses recursion and its use in problem solving. A visual trace of recursive calls is provided, and recursive applications are discussed. Many recursive algorithms are presented, including recursive functions for finding factorials, finding a greatest common denominator (GCD), performing a binary search, and sorting (QuickSort). The classic Towers of Hanoi example is also presented. For students who need more challenge, there is a section on exhaustive algorithms.

## Chapter 21: Binary Trees

This chapter covers the binary tree ADT and demonstrates many binary tree operations. The student learns to traverse a tree, insert an element, delete an element, replace an element, test for an element, and destroy a tree.

## Appendix A: The ASCII Character Set

A list of the ASCII and Extended ASCII characters and their codes

## Appendix B: Operator Precedence and Associativity

A chart showing the C++ operators and their precedence
The following appendices are available online at www.pearsonglobaleditions.com/gaddis.

## Appendix C: Introduction to Flowcharting

A brief introduction to flowcharting. This tutorial discusses sequence, decision, case, repetition, and module structures.

## Appendix D: Using UML in Class Design

This appendix shows the student how to use the Unified Modeling Language to design classes. Notation for showing access specification, data types, parameters, return values, overloaded functions, composition, and inheritance are included.

## Appendix E: Namespaces

This appendix explains namespaces and their purpose. Examples showing how to define a namespace and access its members are given.

## Appendix F: Passing Command Line Arguments

Teaches the student how to write a C++ program that accepts arguments from the command line. This appendix will be useful to students working in a command line environment, such as Unix, Linux, or the Windows command prompt.

## Appendix G: Binary Numbers and Bitwise Operations

A guide to the C++ bitwise operators, as well as a tutorial on the internal storage of integers

## Appendix H: STL Algorithms

This appendix gives a summary of each of the function templates provided by the Standard Template Library (STL), and defined in the <al gorithm> header file.

## Appendix I: Multi-Source File Programs

Provides a tutorial on creating programs that consist of multiple source files. Function header files, class specification files, and class implementation files are discussed.

## Appendix J: Stream Member Functions for Formatting

Covers stream member functions for formatting such as set $f$

## Appendix K: Unions

This appendix introduces unions. It describes the purpose of unions and the difference between a union and a struct, demonstrates how to declare a union and define a union variable, and shows example programs that use unions.

## Appendix L: Answers to Checkpoints

Students may test their own progress by comparing their answers to the Checkpoint exercises against this appendix. The answers to all Checkpoints are included.

## Appendix M: Answers to Odd Numbered Review Questions

Another tool that students can use to gauge their progress

## Features of the Text

Concept Statements
Example Programs

Program Output

## In the Spotlight

VideoNotes

Checkpoints

Notes

Warnings

## Case Studies

## Review Questions and Exercises

Each major section of the text starts with a concept statement. This statement summarizes the ideas of the section.

The text has hundreds of complete example programs, each designed to highlight the topic currently being studied. In most cases, these are practical, real-world examples. Source code for these programs is provided so that students can run the programs themselves.
After each example program, there is a sample of its screen output. This immediately shows the student how the program should function.
Each of these sections provides a programming problem and a detailed, step-by-step analysis showing the student how to solve it.
A series of online videos, developed specifically for this book, is available for viewing at www.pearsonglobaleditions.com/gaddis. Icons appear throughout the text alerting the student to videos about specific topics.
Checkpoints are questions placed throughout each chapter as a selftest study aid. Answers for all Checkpoint questions can be downloaded from the book's Website at www.pearsonglobaleditions.com/ gaddis. This allows students to check how well they have learned a new topic.
Notes appear at appropriate places throughout the text. They are short explanations of interesting or often misunderstood points relevant to the topic at hand.
Warnings are notes that caution the student about certain C++ features, programming techniques, or practices that can lead to malfunctioning programs or lost data.
Case studies that simulate real-world applications appear in many chapters throughout the text. These case studies are designed to highlight the major topics of the chapter in which they appear.
Each chapter presents a thorough and diverse set of review questions, such as fill-in-the-blank and short answer, that check the student's mastery of the basic material presented in the chapter. These are followed by exercises requiring problem solving and analysis, such as the Algorithm Workbench, Predict the Output, and Find the Errors sections. Answers to the odd-numbered review questions and review exercises can be downloaded from the book's Website at www.pearsonglobaleditions.com/gaddis.

## Programming Challenges

## Group Projects

## Software <br> Development Project: <br> Serendipity Booksellers

Each chapter offers a pool of programming exercises designed to solidify the student's knowledge of the topics currently being studied. In most cases, the assignments present real-world problems to be solved. When applicable, these exercises include input validation rules.
There are several group programming projects throughout the text, intended to be constructed by a team of students. One student might build the program's user interface, while another student writes the mathematical code, and another designs and implements a class the program uses. This process is similar to the way many professional programs are written and encourages team work within the classroom.
Available for download from the book's Website at www. pearsonglobaleditions.com/gaddis. This is an ongoing project that instructors can optionally assign to teams of students. It systematically develops a "real-world" software package: a point-of-sale program for the fictitious Serendipity Booksellers organization. The Serendipity assignment for each chapter adds more functionality to the software, using constructs and techniques covered in that chapter. When complete, the program will act as a cash register, manage an inventory database, and produce a variety of reports.
Throughout the text, new $\mathrm{C}++11$ language features are introduced. Look for the $\mathrm{C}++11$ icon to find these new features.

## Supplements

## Student Online Resources

Many student resources are available for this book from the publisher. The following items are available at www.pearsonglobaleditions.com/gaddis:

- The source code for each example program in the book
- Access to the book's VideoNotes
- A full set of appendices, including answers to the Checkpoint questions and answers to the odd-numbered review questions
- A collection of valuable Case Studies
- The complete Serendipity Booksellers Project

## Online Practice and Assessment with MyProgrammingLab

MyProgrammingLab helps students fully grasp the logic, semantics, and syntax of programming. Through practice exercises and immediate, personalized feedback, MyProgrammingLab improves the programming competence of beginning students who often struggle with the basic concepts and paradigms of popular high-level programming languages.

A self-study and homework tool, a MyProgrammingLab course consists of hundreds of small practice exercises organized around the structure of this textbook. For students, the system automatically detects errors in the logic and syntax of their code submissions and offers targeted hints that enable students to figure out what went wrong-and why. For instructors, a comprehensive gradebook tracks correct and incorrect answers and stores the code inputted by students for review.

MyProgrammingLab is offered to users of this book in partnership with Turing's Craft, the makers of the CodeLab interactive programming exercise system. For a full demonstration, to see feedback from instructors and students, or to get started using MyProgrammingLab in your course, visit www.myprogramminglab.com.

## Instructor Resources

The following supplements are available only to qualified instructors:

- Answers to all Review Questions in the text
- Solutions for all Programming Challenges in the text
- PowerPoint presentation slides for every chapter
- Computerized test bank
- Answers to all Student Lab Manual questions
- Solutions for all Student Lab Manual programs

Visit the Pearson Instructor Resource Center (www.pearsonglobaleditions.com/gaddis) for information on how to access instructor resources.

## Textbook Web site

Student and instructor resources, including links to download Microsoft ${ }^{\circledR}$ Visual Studio Express and other popular IDEs, for all the books in the Gaddis Starting Out with series can be accessed at the following URL:
http://www.pearsonglobaleditions.com/gaddis

## Which Gaddis C++ book is right for you?

The Starting Out with C++ Series includes three books, one of which is sure to fit your course:

- Starting Out with C++: From Control Structures through Objects
- Starting Out with C++: Early Objects
- Starting Out with C++: Brief Version

The following chart will help you determine which book is right for your course.

## FROM CONTROL STRUCTURES <br> THROUGH OBJECTS <br> - BRIEF VERSION

## LATE INTRODUCTION OF OBJECTS

Classes are introduced in Chapter 13 of the standard text and Chapter 11 of the brief text, after control structures, functions, arrays, and pointers. Advanced OOP topics, such as inheritance and polymorphism, are covered in the following two chapters.

## INTRODUCTION OF DATA STRUCTURES AND RECURSION

Linked lists, stacks and queues, and binary trees are introduced in the final chapters of the standard text. Recursion is covered after stacks and queues, but before binary trees. These topics are not covered in the brief text, though it does have appendices dealing with linked lists and recursion.

## - EARLY OBJECTS

## EARLIER INTRODUCTION OF OBJECTS

Classes are introduced in Chapter 7, after control structures and functions, but before arrays and pointers. Their use is then integrated into the remainder of the text. Advanced OOP topics, such as inheritance and polymorphism, are covered in Chapters 11 and 15.

## INTRODUCTION OF DATA STRUCTURES AND RECURSION

Linked lists, stacks and queues, and binary trees are introduced in the final chapters of the text, after the chapter on recursion.

## Acknowledgments

There have been many helping hands in the development and publication of this text. We would like to thank the following faculty reviewers for their helpful suggestions and expertise.

I would also like to thank my family and friends for their support in all of my projects. I am extremely fortunate to have Matt Goldstein as my editor, and Kristy Alaura as editorial assistant. Their guidance and encouragement made it a pleasure to write chapters and meet deadlines. I am also fortunate to have Demetrius Hall as my marketing manager. His hard work is truly inspiring, and he does a great job of getting this book out to the academic community. The production team, led by Sandra Rodriguez, worked tirelessly to make this book a reality. Thanks to you all!

## About the Author

Tony Gaddis is the principal author of the Starting Out with series of textbooks. He has nearly two decades of experience teaching computer science courses, primarily at Haywood Community College. Tony is a highly acclaimed instructor who was previously selected as the North Carolina Community College Teacher of the Year and has received the Teaching Excellence award from the National Institute for Staff and Organizational Development. The Starting Out with series includes introductory textbooks covering Programming Logic and Design, Alice, C++, Java ${ }^{\mathrm{TM}}$, Microsoft ${ }^{\circledR}$ Visual Basic ${ }^{\circledR}$, Microsoft ${ }^{\circledR}$ Visual C\#, Python, and App Inventor, all published by Pearson.

## Acknowledgments for the Global Edition

Pearson would like to thank the following people for their contributions to the Global Edition.

## MyProgrammingLab"

Through the power of practice and immediate personalized feedback, MyProgrammingLab helps improve your students' performance.

## PROGRAMMING PRACTICE

With MyProgrammingLab, your students will gain first-hand programming experience in an interactive online environment.

## IMMEDIATE, PERSONALIZED FEEDBACK

MyProgrammingLab automatically detects errors in the logic and syntax of their code submission and offers targeted hints that enables students to figure out what went wrong and why.

## GRADUATED COMPLEXITY

MyProgrammingLab breaks down programming concepts into short, understandable sequences of exercises. Within each sequence the level and sophistication of the exercises increase gradually but steadily.

## DYNAMIC ROSTER

Students' submissions are stored in a roster that indicates whether the submission is correct, how many attempts were made, and the actual code submissions from each attempt.

## PEARSON eTEXT

The Pearson eText gives students access to their textbook anytime, anywhere.

## STEP-BY-STEP VIDEONOTE TUTORIALS

These step-by-step video tutorials enhance the programming concepts presented in select Pearson textbooks.

## 1 Introduction to Computers and Programming

TOPICS
1.1 Why Program?
1.2 Computer Systems: Hardware and Software
1.3 Programs and Programming Languages

$$
\begin{array}{ll}
\text { 1.4 } & \text { What Is a Program Made of? } \\
\text { 1.5 } & \text { Input, Processing, and Output } \\
\text { 1.6 } & \text { The Programming Process } \\
\text { 1.7 } & \text { Procedural and Object-Oriented } \\
& \text { Programming }
\end{array}
$$

### 1.1 Why Program?

CONCEPT: Computers can do many different jobs because they are programmable.
Think about some of the different ways that people use computers. In school, students use computers for tasks such as writing papers, searching for articles, sending e-mail, and participating in online classes. At work, people use computers to conduct business transactions, communicate with customers and coworkers, analyze data, make presentations, control machines in manufacturing facilities, and many many other tasks. At home, people use computers for tasks such as paying bills, shopping online, social networking, and playing computer games. And don't forget that smartphones, MP3 players, DVRs, car navigation systems, and many other devices are computers as well. The uses of computers are almost limitless in our everyday lives.

Computers can do such a wide variety of things because they can be programmed. This means computers are not designed to do just one job, but any job that their programs tell them to do. A program is a set of instructions that a computer follows to perform a task. For example, Figure 1-1 shows screens using Microsoft Word and PowerPoint, two commonly used programs.

Programs are commonly referred to as software. Software is essential to a computer because without software, a computer can do nothing. All of the software we use to make our computers useful is created by individuals known as programmers or software developers. A programmer, or software developer, is a person with the training and skills necessary to design, create, and test computer programs. Computer programming is an exciting and rewarding career. Today, you will find programmers working in business, medicine, government, law enforcement, agriculture, academia, entertainment, and almost every other field.

Figure 1-1 A word processing program and a presentation program

Computer programming is both an art and a science. It is an art because every aspect of a program should be carefully designed. Listed below are a few of the things that must be designed for any real-world computer program:

- The logical flow of the instructions
- The mathematical procedures
- The appearance of the screens
- The way information is presented to the user
- The program's "user-friendliness"
- Documentation, help files, tutorials, and so on

There is also a scientific, or engineering, side to programming. Because programs rarely work right the first time they are written, a lot of testing, correction, and redesigning is required. This demands patience and persistence from the programmer. Writing software demands discipline as well. Programmers must learn special languages like C++ because computers do not understand English or other human languages. Languages such as C++ have strict rules that must be carefully followed.

Both the artistic and scientific nature of programming make writing computer software like designing a car: Both cars and programs should be functional, efficient, powerful, easy to use, and pleasing to look at.

### 1.2 Computer Systems: Hardware and Software

CONCEPT: All computer systems consist of similar hardware devices and software components. This section provides an overview of standard computer hardware and software organization.

## Hardware

Hardware refers to the physical components of which a computer is made. A computer, as we generally think of it, is not an individual device, but a system of devices. Like the instruments in a symphony orchestra, each device plays its own part. A typical computer system consists of the following major components:

- The central processing unit (CPU)
- Main memory
- Secondary storage devices
- Input devices
- Output devices

The organization of a computer system is depicted in Figure 1-2.
Figure 1-2 Typical devices in a computer system

## The CPU

When a computer is performing the tasks that a program tells it to do, we say that the computer is running or executing the program. The central processing unit, or CPU, is the part of a computer that actually runs programs. The CPU is the most important component in a computer because without it, the computer could not run software.
In the earliest computers, CPUs were huge devices made of electrical and mechanical components such as vacuum tubes and switches. Figure 1-3 shows such a device. The two women in

Figure 1-3 The ENIAC computer

the photo are working with the historic ENIAC computer. The ENIAC, considered by many to be the world's first programmable electronic computer, was built in 1945 to calculate artillery ballistic tables for the U.S. Army. This machine, which was primarily one big CPU, was 8 feet tall, 100 feet long, and weighed 30 tons.

Today, CPUs are small chips known as microprocessors. Figure 1-4 shows a photo of a lab technician holding a modern-day microprocessor. In addition to being much smaller than the old electromechanical CPUs in early computers, microprocessors are also much more powerful.

Figure 1-4 A microprocessor

The CPU's job is to fetch instructions, follow the instructions, and produce some result. Internally, the central processing unit consists of two parts: the control unit and the arithmetic and logic unit (ALU). The control unit coordinates all of the computer's operations. It is responsible for determining where to get the next instruction and regulating the other major components of the computer with control signals. The arithmetic and logic unit, as its name suggests, is designed to perform mathematical operations. The organization of the CPU is shown in Figure 1-5.

Figure 1-5 Organization of a CPU

A program is a sequence of instructions stored in the computer's memory. When a computer is running a program, the CPU is engaged in a process known formally as the fetch/ decode/execute cycle. The steps in the fetch/decode/execute cycle are as follows:
Fetch The CPU's control unit fetches, from main memory, the next instruction in the sequence of program instructions.
Decode The instruction is encoded in the form of a number. The control unit decodes the instruction and generates an electronic signal.
Execute The signal is routed to the appropriate component of the computer (such as the ALU, a disk drive, or some other device). The signal causes the component to perform an operation.
These steps are repeated as long as there are instructions to perform.

## Main Memory

You can think of main memory as the computer's work area. This is where the computer stores a program while the program is running, as well as the data with which the program is working. For example, suppose you are using a word processing program to write an essay for one of your classes. While you do this, both the word processing program and the essay are stored in main memory.
Main memory is commonly known as random-access memory or RAM. It is called this because the CPU is able to quickly access data stored at any random location in RAM. RAM is usually a volatile type of memory that is used only for temporary storage while a program is running. When the computer is turned off, the contents of RAM are erased. Inside your computer, RAM is stored in small chips.
A computer's memory is divided into tiny storage locations known as bytes. One byte is enough memory to store only a letter of the alphabet or a small number. In order to do
anything meaningful, a computer must have lots of bytes. Most computers today have millions, or even billions, of bytes of memory.
Each byte is divided into eight smaller storage locations known as bits. The term bit stands for binary digit. Computer scientists usually think of bits as tiny switches that can be either on or off. Bits aren't actual "switches," however, at least not in the conventional sense. In most computer systems, bits are tiny electrical components that can hold either a positive or a negative charge. Computer scientists think of a positive charge as a switch in the on position, and a negative charge as a switch in the off position.
Each byte is assigned a unique number known as an address. The addresses are ordered from lowest to highest. A byte is identified by its address in much the same way a post office box is identified by an address. Figure 1-6 shows a group of memory cells with their addresses. In the illustration, sample data is stored in memory. The number 149 is stored in the cell with the address 16 , and the number 72 is stored at address 23 .

Figure 1-6 Memory

| 0 | 1 | 2 | 3 |  | 4 | 5 | 6 |  | 7 | 8 | 9 |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 10 | 11 | 12 | 13 |  | 14 | 15 | 16 | 149 | 17 | 18 | 19 |  |
| 20 | 21 | 22 | 23 | 72 | 24 | 25 | 26 |  | 27 | 28 | 29 |  |

## Secondary Storage

Secondary storage is a type of memory that can hold data for long periods of time, even when there is no power to the computer. Programs are normally stored in secondary memory and loaded into main memory as needed. Important data such as word processing documents, payroll data, and inventory records is saved to secondary storage as well.
The most common type of secondary storage device is the disk drive. A traditional disk drive stores data by magnetically encoding it onto a circular disk. Solid-state drives, which store data in solid-state memory, are increasingly becoming popular. A solid-state drive has no moving parts and operates faster than a traditional disk drive. Most computers have some sort of secondary storage device, either a traditional disk drive or a solid-state drive, mounted inside their case. External storage devices can be used to create backup copies of important data or to move data to another computer. For example, USB (Universal Serial Bus) drives and SD (Secure Digital) memory cards are small devices that appear in the system as disk drives. They are inexpensive, reliable, and small enough to be carried in your pocket.

Optical devices such as the $C D$ (compact disc) and the $D V D$ (digital versatile disc) are also used for data storage. Data is not recorded magnetically on an optical disc, but is encoded as a series of pits on the disc surface. CD and DVD drives use a laser to detect the pits and thus read the encoded data. Optical discs hold large amounts of data, and because recordable CD and DVD drives are now commonplace, they are good mediums for creating backup copies of data.

## Input Devices

Input is any data the computer collects from the outside world. The device that collects the information and sends it to the computer is called an input device. Common input devices are the keyboard, mouse, touchscreen, scanner, digital camera, and microphone. Disk drives, CD/DVD drives, and USB drives can also be considered input devices because programs and information are retrieved from them and loaded into the computer's memory.

## Output Devices

Output is any information the computer sends to the outside world. It might be a sales report, a list of names, or a graphic image. The information is sent to an output device, which formats and presents it. Common output devices are screens, printers, and speakers. Storage devices can also be considered output devices because the CPU sends them data to be saved.

## Software

If a computer is to function, software is not optional. Everything a computer does, from the time you turn the power switch on until you shut the system down, is under the control of software. There are two general categories of software: system software and application software. Most computer programs clearly fit into one of these two categories. Let's take a closer look at each.

## System Software

The programs that control and manage the basic operations of a computer are generally referred to as system software. System software typically includes the following types of programs:

- Operating Systems

An operating system is the most fundamental set of programs on a computer. The operating system controls the internal operations of the computer's hardware, manages all the devices connected to the computer, allows data to be saved to and retrieved from storage devices, and allows other programs to run on the computer.

## - Utility Programs

A utility program performs a specialized task that enhances the computer's operation or safeguards data. Examples of utility programs are virus scanners, file-compression programs, and data-backup programs.

- Software Development Tools

The software tools that programmers use to create, modify, and test software are referred to as software development tools. Compilers and integrated development environments, which we will discuss later in this chapter, are examples of programs that fall into this category.

## Application Software

Programs that make a computer useful for everyday tasks are known as application software. These are the programs that people normally spend most of their time running on their computers. Figure 1-1, at the beginning of this chapter, shows screens from two commonly used applications-Microsoft Word, a word processing program, and Microsoft

PowerPoint, a presentation program. Some other examples of application software are spreadsheet programs, e-mail programs, web browsers, and game programs.

## Checkpoint

1.1 Why is the computer used by so many different people, in so many different professions?
1.2 List the five major hardware components of a computer system.
1.3 Internally, the CPU consists of what two units?
1.4 Describe the steps in the fetch/decode/execute cycle.
1.5 What is a memory address? What is its purpose?
1.6 Explain why computers have both main memory and secondary storage.
1.7 What are the two general categories of software?
1.8 What fundamental set of programs control the internal operations of the computer's hardware?
1.9 What do you call a program that performs a specialized task, such as a virus scanner, a file-compression program, or a data-backup program?
1.10 Word processing programs, spreadsheet programs, e-mail programs, web browsers, and game programs belong to what category of software?

### 1.3 Programs and Programming Languages

CONCEPT: A program is a set of instructions a computer follows in order to perform a task. A programming language is a special language used to write computer programs.

## What Is a Program?

Computers are designed to follow instructions. A computer program is a set of instructions that tells the computer how to solve a problem or perform a task. For example, suppose we want the computer to calculate someone's gross pay. Here is a list of things the computer should do:

1. Display a message on the screen asking "How many hours did you work?"
2. Wait for the user to enter the number of hours worked. Once the user enters a number, store it in memory.
3. Display a message on the screen asking "How much do you get paid per hour?"
4. Wait for the user to enter an hourly pay rate. Once the user enters a number, store it in memory.
5. Multiply the number of hours by the amount paid per hour, and store the result in memory.
6. Display a message on the screen that tells the amount of money earned. The message must include the result of the calculation performed in Step 5.

Collectively, these instructions are called an algorithm. An algorithm is a set of well-defined steps for performing a task or solving a problem. Notice these steps are sequentially ordered. Step 1 should be performed before Step 2, and so forth. It is important that these instructions be performed in their proper sequence.

Although you and I might easily understand the instructions in the pay-calculating algorithm, it is not ready to be executed on a computer. A computer's CPU can only process instructions that are written in machine language. If you were to look at a machine language program, you would see a stream of binary numbers (numbers consisting of only 1 s and 0 s ). The binary numbers form machine language instructions, which the CPU interprets as commands. Here is an example of what a machine language instruction might look like:

1011010000000101
As you can imagine, the process of encoding an algorithm in machine language is very tedious and difficult. In addition, each different type of CPU has its own machine language. If you wrote a machine language program for computer $A$ then wanted to run it on computer $B$, which has a different type of CPU, you would have to rewrite the program in computer B's machine language.

Programming languages, which use words instead of numbers, were invented to ease the task of programming. A program can be written in a programming language, such as C++, which is much easier to understand than machine language. Programmers save their programs in text files, then use special software to convert their programs to machine language.

Program 1-1 shows how the pay-calculating algorithm might be written in C++.
The "Program Output with Example Input" shows what the program will display on the screen when it is running. In the example, the user enters 10 for the number of hours worked and 15 for the hourly pay rate. The program displays the earnings, which are $\$ 150$.

NOTE: The line numbers that are shown in Program 1-1 are not part of the program. This book shows line numbers in all program listings to help point out specific parts of the program.

## Program 1-1

```
// This program calculates the user's pay.
#include <iostream>
using namespace std;
int main()
{
    double hours, rate, pay;
    // Get the number of hours worked.
    cout << "How many hours did you work? ";
    cin >> hours;
    // Get the hourly pay rate.
    cout << "How much do you get paid per hour? ";
    cin >> rate;
    // Calculate the pay.
    pay = hours * rate;
```

```
Program 1-1 (continued)
19
20 // Display the pay.
21
22
cout << "You have earned $" << pay << endl;
return 0;
}
```

## Program Output with Example Input Shown in Bold

```
How many hours did you work? 10 Enter
How much do you get paid per hour? 15 Enter
You have earned $150
```

## Programming Languages

In a broad sense, there are two categories of programming languages: low-level and highlevel. A low-level language is close to the level of the computer, which means it resembles the numeric machine language of the computer more than the natural language of humans. The easiest languages for people to learn are high-level languages. They are called "highlevel" because they are closer to the level of human readability than computer readability. Figure 1-7 illustrates the concept of language levels.

Figure 1-7 Low-level versus high-level languages
High level (easily understood by humans)
 1010001011101011

Many high-level languages have been created. Table 1-1 lists a few of the well-known ones.
In addition to the high-level features necessary for writing applications such as payroll systems and inventory programs, $\mathrm{C}++$ also has many low-level features. $\mathrm{C}++$ is based on the C language, which was invented for purposes such as writing operating systems and compilers. Since C++ evolved from C, it carries all of C's low-level capabilities with it.

Table 1-1 Programming Languages
\(\left.$$

both high-level and low-level features. <br>
Based on the C language, C++ offers object-oriented features not found in C. Also <br>

invented at Bell Laboratories.\end{array}\right]\)| Pronounced "C sharp." A language invented by Microsoft for developing applica- |
| :--- |
| tions based on the Microsoft .NET platform. |

C++ is popular not only because of its mixture of low- and high-level features, but also because of its portability. This means that a C++ program can be written on one type of computer, then run on many other types of systems. This usually requires the program to be recompiled on each type of system, but the program itself may need little or no change.

NOTE: Programs written for specific graphical environments often require significant changes when moved to a different type of system. Examples of such graphical environments are Windows, the X-Window System, and the macOS operating system.

## Source Code, Object Code, and Executable Code

When a C++ program is written, it must be typed into the computer and saved to a file. A text editor, which is similar to a word processing program, is used for this task. The statements written by the programmer are called source code, and the file they are saved in is called the source file.

After the source code is saved to a file, the process of translating it to machine language can begin. During the first phase of this process, a program called the preprocessor reads the source code. The preprocessor searches for special lines that begin with the \# symbol. These lines contain commands that cause the preprocessor to modify the source code in some way.

During the next phase, the compiler steps through the preprocessed source code, translating each source code instruction into the appropriate machine language instruction. This process will uncover any syntax errors that may be in the program. Syntax errors are illegal uses of key words, operators, punctuation, and other language elements. If the program is free of syntax errors, the compiler stores the translated machine language instructions, which are called object code, in an object file.

Although an object file contains machine language instructions, it is not a complete program. Here is why: C++ is conveniently equipped with a library of prewritten code for performing common operations or sometimes-difficult tasks. For example, the library contains hardware-specific code for displaying messages on the screen and reading input from the keyboard. It also provides routines for mathematical functions, such as calculating the square root of a number. This collection of code, called the runtime library, is extensive. Programs almost always use some part of it. When the compiler generates an object file, however, it does not include machine code for any runtime library routines the programmer might have used. During the last phase of the translation process, another program called the linker combines the object file with the necessary library routines. Once the linker has finished with this step, an executable file is created. The executable file contains machine language instructions, or executable code, and is ready to run on the computer.
Figure 1-8 illustrates the process of translating a C++ source file into an executable file.
The entire process of invoking the preprocessor, compiler, and linker can be initiated with a single action. For example, on a Linux system, the following command causes the C++ program named hello.cpp to be preprocessed, compiled, and linked. The executable code is stored in a file named hello.

```
g++ -o hello hello.cpp
```

Figure 1-8 Translating a C++ source file to an executable file

Appendix F explains how compiling works in .Net. You can download Appendix F from the Computer Science Portal at www.pearsonglobaleditions.com/gaddis.

Many development systems, particularly those on personal computers, have integrated development environments (IDEs). These environments consist of a text editor, compiler, debugger, and other utilities integrated into a package with a single set of menus. Preprocessing, compiling, linking, and even executing a program is done with a single click of a button, or by selecting a single item from a menu. Figure 1-9 shows a screen from the Microsoft Visual Studio IDE.

Figure 1-9 An integrated development environment (IDE)

## Checkpoint

### 1.11 What is an algorithm?

1.12 Why were computer programming languages invented?
1.13 What is the difference between a high-level language and a low-level language?
1.14 What does portability mean?
1.15 Explain the operations carried out by the preprocessor, compiler, and linker.
1.16 Explain what is stored in a source file, an object file, and an executable file.
1.17 What is an integrated development environment?

### 1.4 What Is a Program Made of?

CONCEPT: There are certain elements that are common to all programming languages.

## Language Elements

All programming languages have a few things in common. Table 1-2 lists the common elements you will find in almost every language.

Table 1-2 Language Elements

| Language Element | Description |
| :--- | :--- |
| Key Words | Words that have a special meaning. Key words may only be used for <br> their intended purpose. Key words are also known as reserved words. |
| Programmer-Defined | Words or names defined by the programmer. They are symbolic names <br> that refer to variables or programming routines. |
| Operators | Operators perform operations on one or more operands. An operand is <br> usually a piece of data, like a number. |
| Punctuation | Punctuation characters that mark the beginning or end of a statement, or <br> separate items in a list. |
| Syntax | Rules that must be followed when constructing a program. Syntax dictates <br> how key words and operators may be used, and where punctuation <br> symbols must appear. |

Let's look at some specific parts of Program 1-1 (the pay-calculating program) to see examples of each element listed in the table above. For your convenience, Program 1-1 is listed again.

## Program 1-1

```
// This program calculates the user's pay.
#include <iostream>
using namespace std;
int main()
{
    double hours, rate, pay;
    // Get the number of hours worked.
    cout << "How many hours did you work? ";
    cin >> hours;
    // Get the hourly pay rate.
    cout << "How much do you get paid per hour? ";
    cin >> rate;
    // Calculate the pay.
    pay = hours * rate;
```

\}
// Display the pay.
cout << "You have earned \$" << pay << endl;
return 0;

## Key Words (Reserved Words)

Three of C++'s key words appear on lines 3 and 5: using, namespace, and int. The word double, which appears on line 7 , is also a C++ key word. These words, which are always written in lowercase, each have a special meaning in C++ and can only be used for their intended purposes. As you will see, the programmer is allowed to make up his or her own names for certain things in a program. Key words, however, are reserved and cannot be used for anything other than their designated purposes. Part of learning a programming language is learning what the key words are, what they mean, and how to use them.

NOTE: The \#include <iostream> statement in line 2 is a preprocessor directive.

NOTE: In C++, key words are written in all lowercase.

## Programmer-Defined Identifiers

The words hours, rate, and pay that appear in the program on lines $7,11,15,18$, and 21 are programmer-defined identifiers. They are not part of the C++ language, but rather are names made up by the programmer. In this particular program, these are the names of variables. As you will learn later in this chapter, variables are the names of memory locations that may hold data.

## Operators

On line 18 the following code appears:

```
pay = hours * rate;
```

The $=$ and $*$ symbols are both operators. They perform operations on pieces of data known as operands. The * operator multiplies its two operands, which in this example are the variables hours and rate. The $=$ symbol is called the assignment operator. It takes the value of the expression on the right and stores it in the variable whose name appears on the left. In this example, the = operator stores in the pay variable the result of the hours variable multiplied by the rate variable. In other words, the statement says, "Make the pay variable equal to hours times rate, or "pay is assigned the value of hours times rate."

## Punctuation

Notice lines $3,7,10,11,14,15,18,21$, and 22 all end with a semicolon. A semicolon in C++ is similar to a period in English: It marks the end of a complete sentence (or statement, as it is called in programming jargon). Semicolons do not appear at the end of every line in a C++ program, however. There are rules that govern where semicolons are required and
where they are not. Part of learning C++ is learning where to place semicolons and other punctuation symbols.

## Lines and Statements

Often, the contents of a program are thought of in terms of lines and statements. A "line" is just that-a single line as it appears in the body of a program. Program 1-1 has 23 lines. Most of the lines contain something meaningful; however, some of the lines are empty. The blank lines are only there to make the program more readable.

A statement is a complete instruction that causes the computer to perform some action. Here is the statement that appears in line 10 of Program 1-1:

```
cout << "How many hours did you work? ";
```

This statement causes the computer to display the message "How many hours did you work?" on the screen. Statements can be a combination of key words, operators, and programmerdefined symbols. Statements often occupy only one line in a program, but sometimes they are spread out over more than one line.

## Variables

A variable is a named storage location in the computer's memory for holding a piece of information. The information stored in variables may change while the program is running (hence the name "variable"). Notice in Program 1-1 the words hours, rate, and pay appear in several places. All three of these are the names of variables. The hours variable is used to store the number of hours the user has worked. The rate variable stores the user's hourly pay rate. The pay variable holds the result of hours multiplied by rate, which is the user's gross pay.

NOTE: Notice the variables in Program 1-1 have names that reflect their purpose. In fact, it would be easy to guess what the variables were used for just by reading their names. This will be discussed further in Chapter 2.

Variables are symbolic names that represent locations in the computer's random-access memory (RAM). When information is stored in a variable, it is actually stored in RAM. Assume a program has a variable named length. Figure 1-10 illustrates the way the variable name represents a memory location.

Figure 1-10 A variable name represents a memory location

In Figure 1-10, the variable 1ength is holding the value 72 . The number 72 is actually stored in RAM at address 23, but the name length symbolically represents this storage location. If it helps, you can think of a variable as a box that holds information. In Figure 1-10, the number 72 is stored in the box named length. Only one item may be stored in the box at any given time. If the program stores another value in the box, it will take the place of the number 72 .

## Variable Definitions

In programming, there are two general types of data: numbers and characters. Numbers are used to perform mathematical operations, and characters are used to print data on the screen or on paper.
Numeric data can be categorized even further. For instance, the following are all whole numbers or integers:

```
5
```

7
-129
32154

The following are real or floating-point numbers:
3.14159
6.7
1.0002

When creating a variable in a C++ program, you must know what type of data the program will be storing in it. Look at line 7 of Program 1-1:

```
double hours, rate, pay;
```

The word double in this statement indicates that the variables hours, rate, and pay will be used to hold double precision floating-point numbers. This statement is called a variable definition. It is used to define one or more variables that will be used in the program and to indicate the type of data they will hold. The variable definition causes the variables to be created in memory, so all variables must be defined before they can be used. If you review the listing of Program 1-1, you will see that the variable definitions come before any other statements using those variables.

NOTE: Programmers often use the term "variable declaration" to mean the same thing as "variable definition." Strictly speaking, there is a difference between the two terms. A definition statement always causes a variable to be created in memory. Some types of declaration statements, however, do not cause a variable to be created in memory. You will learn more about declarations later in this book.

### 1.5 Input, Processing, and Output

CONCEPT: The three primary activities of a program are input, processing, and output.
Computer programs typically perform a three-step process of gathering input, performing some process on the information gathered, then producing output. Input is information a
program collects from the outside world. It can be sent to the program from the user, who is entering data at the keyboard or using the mouse. It can also be read from disk files or hardware devices connected to the computer. Program 1-1 allows the user to enter two pieces of information: the number of hours worked and the hourly pay rate. Lines 11 and 15 use the cin (pronounced "see in") object to perform these input operations:

```
cin >> hours;
cin >> rate;
```

Once information is gathered from the outside world, a program usually processes it in some manner. In Program 1-1, the hours worked and hourly pay rate are multiplied in line 18 , and the result is assigned to the pay variable:

```
pay = hours * rate;
```

Output is information that a program sends to the outside world. It can be words or graphics displayed on a screen, a report sent to the printer, data stored in a file, or information sent to any device connected to the computer. Lines 10, 14, and 21 in Program 1-1 all perform output:

```
cout << "How many hours did you work? ";
cout << "How much do you get paid per hour? ";
cout << "You have earned $" << pay << endl;
```

These lines use the cout (pronounced "see out") object to display messages on the computer's screen. You will learn more details about the cin and cout objects in Chapter 2.

## Checkpoint

1.18 Describe the difference between a key word and a programmer-defined identifier.
1.19 Describe the difference between operators and punctuation symbols.
1.20 Describe the difference between a program line and a statement.
1.21 Why are variables called "variable"?
1.22 What happens to a variable's current contents when a new value is stored there?
1.23 What must take place in a program before a variable is used?
1.24 What are the three primary activities of a program?

### 1.6 The Programming Process

CONCEPT: The programming process consists of several steps, which include design, creation, testing, and debugging activities.

## Designing and Creating a Program

Now that you have been introduced to what a program is, it's time to consider the process of creating a program. Quite often, when inexperienced students are given programming assignments, they have trouble getting started because they don't know what to do first. If you find yourself in this dilemma, the steps listed in Figure 1-11 may help. These are the steps recommended for the process of writing a program.

Figure 1-11 Steps for writing a program

1. Clearly define what the program is to do.
2. Visualize the program running on the computer.
3. Use design tools such as a hierarchy chart, flowcharts, or pseudocode to create a model of the program.
4. Check the model for logical errors.
5. Type the code, save it, and compile it.
6. Correct any errors found during compilation. Repeat Steps 5 and 6 as many times as necessary.
7. Run the program with test data for input.
8. Correct any errors found while running the program. Repeat Steps 5 through 8 as many times as necessary.
9. Validate the results of the program.

The steps listed in Figure 1-11 emphasize the importance of planning. Just as there are good ways and bad ways to paint a house, there are good ways and bad ways to create a program. A good program always begins with planning.

With the pay-calculating program as our example, let's look at each of the steps in more detail.

1. Clearly define what the program is to do.

This step requires that you identify the purpose of the program, the information that is to be input, the processing that is to take place, and the desired output. Let's examine each of these requirements for the example program:

Purpose To calculate the user's gross pay.
Input Number of hours worked, hourly pay rate.
Process Multiply number of hours worked by hourly pay rate. The result is the user's gross pay.
Output Display a message indicating the user's gross pay.

## 2. Visualize the program running on the computer.

Before you create a program on the computer, you should first create it in your mind. Step 2 is the visualization of the program. Try to imagine what the computer screen looks like while the program is running. If it helps, draw pictures of the screen, with sample input and output, at various points in the program. For instance, here is the screen produced by the pay-calculating program:

```
How many hours did you work? 10
How much do you get paid per hour? 15
You have earned $150
```

In this step, you must put yourself in the shoes of the user. What messages should the program display? What questions should it ask? By addressing these concerns, you will have already determined most of the program's output.
3. Use design tools such as a hierarchy chart, flowcharts, or pseudocode to create a model of the program.

While planning a program, the programmer uses one or more design tools to create a model of the program. Three common design tools are hierarchy charts, flowcharts, and pseudocode. A bierarchy chart is a diagram that graphically depicts the structure of a program. It has boxes that represent each step in the program. The boxes are connected in a way that illustrates their relationship to one another. Figure 1-12 shows a hierarchy chart for the pay-calculating program.

Figure 1-12 Hierarchy chart

A hierarchy chart begins with the overall task then refines it into smaller subtasks. Each of the subtasks is then refined into even smaller sets of subtasks, until each is small enough to be easily performed. For instance, in Figure 1-12, the overall task "Calculate Gross Pay" is listed in the top-level box. That task is broken into three subtasks. The first subtask, "Get Payroll Data from User," is broken further into two subtasks. This process of "divide and conquer" is known as top-down design.

Introduction to Flowcharting

A flowchart is a diagram that shows the logical flow of a program. It is a useful tool for planning each operation a program performs and the order in which the operations are to occur. For more information see Appendix C, Introduction to Flowcharting.
Pseudocode is a cross between human language and a programming language. Although the computer can't understand pseudocode, programmers often find it helpful to write an algorithm in a language that's "almost" a programming language, but still very similar to natural language. For example, here is pseudocode that describes the pay-calculating program:

Get payroll data.
Calculate gross pay.
Display gross pay.
Although the pseudocode above gives a broad view of the program, it doesn't reveal all the program's details. A more detailed version of the pseudocode follows:

Display "How many hours did you work?".
Input hours.
Display "How much do you get paid per hour?".
Input rate.
Store the value of hours times rate in the pay variable.
Display the value in the pay variable.
Notice the pseudocode contains statements that look more like commands than the English statements that describe the algorithm in Section 1.4 (What Is a Program Made of?). The pseudocode even names variables and describes mathematical operations.

## 4. Check the model for logical errors.

Logical errors are mistakes that cause the program to produce erroneous results. Once a hierarchy chart, flowchart, or pseudocode model of the program is assembled, it should be checked for these errors. The programmer should trace through the charts or pseudocode, checking the logic of each step. If an error is found, the model can be corrected before the next step is attempted.
5. Type the code, save it, and compile it.

Once a model of the program (hierarchy chart, flowchart, or pseudocode) has been created, checked, and corrected, the programmer is ready to write source code on the computer. The programmer saves the source code to a file and begins the process of translating it to machine language. During this step, the compiler will find any syntax errors that may exist in the program.
6. Correct any errors found during compilation. Repeat Steps 5 and 6 as many times as necessary.
If the compiler reports any errors, they must be corrected. Steps 5 and 6 must be repeated until the program is free of compile-time errors.
7. Run the program with test data for input.

Once an executable file is generated, the program is ready to be tested for runtime errors. A runtime error is an error that occurs while the program is running. These are usually logical errors, such as mathematical mistakes.

Testing for runtime errors requires that the program be executed with sample data or sample input. The sample data should be such that the correct output can be predicted. If the program does not produce the correct output, a logical error is present in the program.
8. Correct any errors found while running the program. Repeat Steps 5 through 8 as many times as necessary.

When runtime errors are found in a program, they must be corrected. You must identify the step where the error occurred and determine the cause. Desk-checking is a process that can help locate runtime errors. The term desk-checking means the programmer starts reading the program, or a portion of the program, and steps through each statement. A sheet of paper is often used in this process to jot down the current contents of all variables and sketch what the screen looks like after each output operation. When a variable's contents change, or information is displayed on the screen, this is noted. By stepping through each statement, many errors can be located and corrected. If an error is a result of incorrect logic (such as an improperly stated math formula), you must correct the statement or statements involved in
the logic. If an error is due to an incomplete understanding of the program requirements, then you must restate the program purpose and modify the hierarchy and/or flowcharts, pseudocode, and source code. The program must then be saved, recompiled, and retested. This means Steps 5 through 8 must be repeated until the program reliably produces satisfactory results.
9. Validate the results of the program.

When you believe you have corrected all the runtime errors, enter test data and determine whether the program solves the original problem.

## What Is Software Engineering?

The field of software engineering encompasses the whole process of crafting computer software. It includes designing, writing, testing, debugging, documenting, modifying, and maintaining complex software development projects. Like traditional engineers, software engineers use a number of tools in their craft. Here are a few examples:

- Program specifications
- Charts and diagrams of screen output
- Hierarchy charts and flowcharts
- Pseudocode
- Examples of expected input and desired output
- Special software designed for testing programs

Most commercial software applications are very large. In many instances, one or more teams of programmers, not a single individual, develop them. It is important that the program requirements be thoroughly analyzed and divided into subtasks that are handled by individual teams, or individuals within a team.

In Step 3 of the programming process, you were introduced to the hierarchy chart as a tool for top-down design. The subtasks identified in a top-down design can easily become modules, or separate components of a program. If the program is very large or complex, a team of software engineers can be assigned to work on the individual modules. As the project develops, the modules are coordinated to finally become a single software application.

### 1.7 Procedural and Object-Oriented Programming

CONCEPT: Procedural programming and object-oriented programming are two ways of thinking about software development and program design.

C++ is a language that can be used for two methods of writing computer programs: procedural programming and object-oriented programming. This book is designed to teach you some of both.

In procedural programming, the programmer constructs procedures (or functions, as they are called in $\mathrm{C}++)$. The procedures are collections of programming statements that perform a specific task. The procedures each contain their own variables and commonly share variables with other procedures. This is illustrated in Figure 1-13.

Figure 1-13 Procedures in a program

| Program |
| :---: |
| PROCEDURE A |
| Variables |
| Programming |
| END OF PROCEDURE A |

PROCEDURE B
Variables Programming END OF PROCEDURE B

Procedural programming is centered on the procedure, or function. Object-oriented programming (OOP), on the other hand, is centered on the object. An object is a programming element that contains data and the procedures that operate on the data. It is a self-contained unit. This is illustrated in Figure 1-14.

Figure 1-14 Objects in a program

The objects contain, within themselves, both information and the ability to manipulate the information. Operations are carried out on the information in an object by sending the object a message. When an object receives a message instructing it to perform some operation, it carries out the instruction. As you study this text, you will encounter many other aspects of object-oriented programming.

## (1) <br> Checkpoint

1.25 What four items should you identify when defining what a program is to do?
1.26 What does it mean to "visualize a program running"? What is the value of such an activity?
1.27 What is a hierarchy chart?
1.28 Describe the process of desk-checking.
1.29 Describe what a compiler does with a program's source code.

What is a runtime error?
1.31 Is a syntax error (such as misspelling a key word) found by the compiler or when the program is running?
1.32 What is the purpose of testing a program with sample data or input?
1.33 Briefly describe the difference between procedural and object-oriented programming.

## Review Questions and Exercises

## Short Answer

1. Both main memory and secondary storage are types of memory. Describe the difference between the two.
2. What is the difference between system software and application software?
3. What type of software controls the internal operations of the computer's hardware?
4. Why must programs written in a high-level language be translated into machine language before they can be run?
5. Why is it easier to write a program in a high-level language than in machine language?
6. Explain the difference between an object file and an executable file.
7. What is the difference between a syntax error and a logical error?

## Fill-in-the-Blank

8. Computers can do many different jobs because they can be $\qquad$ .
9. The job of the $\qquad$ is to fetch instructions, carry out the operations commanded by the instructions, and produce some outcome or resultant information.
10. The $\qquad$ is the part of a computer in which programs actually execute.
11. The main memory is commonly known as $\qquad$ -.
12. The two general categories of software are $\qquad$ and $\qquad$ .
13. A program is a set of $\qquad$ .
14. $\mathrm{A}(\mathrm{n})$ $\qquad$ is an ordered set of steps written in human language to perform a task or to solve any problem.
15. $\qquad$ is the only language computers really process.
16. $\qquad$ languages are close to the level of humans in terms of readability.
17. C++ is a high-level language that has $\qquad$ features.
18. A program's ability to run on several different types of computer systems is called
$\qquad$ -
19. Words that have special meaning in a programming language are called $\qquad$ .
20. Words or names defined by the programmer are called $\qquad$ .
21. A(n) $\qquad$ translates each source code instruction to the equivalent machine language instruction(s).
22. $\qquad$ characters or symbols mark the beginning or end of programming statements, or separate items in a list.
23. The statement \#include<iostream> is $a(n)$ $\qquad$ .
24. A(n) $\qquad$ is a named storage location.
25. When data is stored in a variable, it is actually stored in the $\qquad$ of the computer.
26. The three primary activities of a program are $\qquad$ , $\longrightarrow$, , and
$\qquad$ _.
27. $\qquad$ is information a program gathers from the outside world.
28. A(n) $\qquad$ is a diagrammatic representation of the logical flow of a program.
29. $\mathrm{A}(\mathrm{n})$ $\qquad$ is a diagram that graphically illustrates the structure of a program.

## Algorithm Workbench

Draw hierarchy charts or flowcharts that depict the programs described below. (See Appendix C for instructions on creating flowcharts.)
30. Available Credit

The following steps should be followed in a program that calculates a customer's available credit:

1. Display the message "Enter the customer's maximum credit."
2. Wait for the user to enter the customer's maximum credit.
3. Display the message "Enter the amount of credit used by the customer."
4. Wait for the user to enter the customer's credit used.
5. Subtract the used credit from the maximum credit to get the customer's available credit.
6. Display a message that shows the customer's available credit.
7. Sales Tax

Design a hierarchy chart or flowchart for a program that calculates the total of a retail sale. The program should ask the user for:

- The retail price of the item being purchased
- The sales tax rate

Once these items have been entered, the program should calculate and display:

- The sales tax for the purchase
- The total of the sale

32. Account Balance

Design a hierarchy chart or flowchart for a program that calculates the current balance in a savings account. The program must ask the user for:

- The starting balance
- The total dollar amount of deposits made
- The total dollar amount of withdrawals made
- The monthly interest rate

Once the program calculates the current balance, it should be displayed on the screen.

## Predict the Result

Questions 33-35 are programs expressed as English statements. What would each display on the screen if they were actual programs?
33. The variable $x$ starts with the value 0 .

The variable $y$ starts with the value 5 .
Add 1 to $x$.
Add 1 to $y$.
Add x and y , and store the result in y .
Display the value in $y$ on the screen.
34. The variable $x$ starts with the value 20 .

The variable $y$ starts with the value 10 .
Store the value of x in a variable t .
Store the value of $y$ in $x$.
Store the value of $t$ in $y$.
Display the value of $x$ on the screen.
Display the value of $y$ on the screen.
35 . The variable a starts with the value 1 .
The variable $b$ starts with the value 10 .
The variable c starts with the value 100 .
The variable x starts with the value 0 .
Store the value of c times 3 in x .
Add the value of $b$ times 6 to the value already in $x$.
Add the value of a times 5 to the value already in $x$.
Display the value in $x$ on the screen.

## Find the Error

36. The following pseudocode algorithm has an error. The program is supposed to ask the user for the length and width of a rectangular room, then display the room's area. The program must multiply the width by the length in order to determine the area. Find the error.
area $=$ width $\times$ length.
Display "What is the room's width?".
Input width.
Display "What is the room's length?".
Input length.
Display area.

### 2.1 The Parts of a C++ Program

CONCEPT: C++ programs have parts and components that serve specific purposes.
Every C++ program has an anatomy. Unlike human anatomy, the parts of C++ programs are not always in the same place. Nevertheless, the parts are there, and your first step in learning $\mathrm{C}++$ is to learn what they are. We will begin by looking at Program 2-1.

Let's examine the program line by line. Here's the first line:

```
// A simple C++ program
```

The // marks the beginning of a comment. The compiler ignores everything from the double slash to the end of the line. That means you can type anything you want on that line and the compiler will never complain! Although comments are not required, they are very important to programmers. Most programs are much more complicated than the example in Program 2-1, and comments help explain what's going on.

## Program 2-1

```
// A simple C++ program
#include <iostream>
using namespace std;
int main()
{
        cout << "Programming is great fun!";
    return 0;
}
```

The output of the program is shown below. This is what appears on the screen when the program runs.

## Program Output

Programming is great fun!

Line 2 looks like this:

```
#include <iostream>
```

Because this line starts with a \#, it is called a preprocessor directive. The preprocessor reads your program before it is compiled and only executes those lines beginning with a \# symbol. Think of the preprocessor as a program that "sets up" your source code for the compiler.

The \#include directive causes the preprocessor to include the contents of another file, known as a header file, in the program. It is called a header file because it should be included at the head, or top, of a program. The word that is enclosed in brackets, iostream, is the name of the header file that is to be included. (The name of the file is iostream. The brackets <> indicate that it is a standard C++ header file.) The <iostream> header file contains code that allows a C++ program to display output on the screen and read input from the keyboard. Because this program uses cout to display screen output, the <iostream> header file must be included. The contents of the <iostream> file are included in the program at the point the \#include statement appears.

Line 3 reads:
using namespace std;
Programs usually contain several items with unique names. In this chapter, you will learn to create variables. In Chapter 6, you will learn to create functions. In Chapter 13, you will learn to create objects. Variables, functions, and objects are examples of program entities that must have names. C++ uses namespaces to organize the names of program entities. The statement using namespace std; declares that the program will be accessing entities whose names are part of the namespace called std. (Yes, even namespaces have names.) The reason the program needs access to the std namespace is because every name created by the iostream file is part of that namespace. In order for a program to use the entities in iostream, it must have access to the std namespace.

Line 5 reads:

```
int main()
```

This marks the beginning of a function. A function can be thought of as a group of one or more programming statements that collectively has a name. The name of this function is main, and the set of parentheses that follows the name indicate that it is a function. The word int stands for "integer." It indicates that the function sends an integer value back to the operating system when it is finished executing.
Although most C++ programs have more than one function, every C++ program must have a function called main. It is the starting point of the program. If you are ever reading someone else's C++ program and want to find where it starts, just look for the function named main.

NOTE: C++ is a case-sensitive language. That means it regards uppercase letters as being entirely different characters than their lowercase counterparts. In C++, the name of the function main must be written in all lowercase letters. C++ doesn't see "Main" the same as "main," or "INT" the same as "int." This is true for all the C++ key words.

Line 6 contains a single, solitary character:
\{
This is called a left brace, or an opening brace, and it is associated with the beginning of the function main. All the statements that make up a function are enclosed in a set of braces. If you look at the third line down from the opening brace, you'll see the closing brace. Everything between the two braces is the content of the function main.

WARNING! Make sure you have a closing brace for every opening brace in your program!

After the opening brace, you see the following statement in line 7:

```
cout << "Programming is great fun!";
```

To put it simply, this line displays a message on the screen. You will read more about cout and the << operator later in this chapter. The message "Programming is great fun!" is printed without the quotation marks. In programming terms, the group of characters inside the quotation marks is called a string literal or string constant.

NOTE: This is the only line in the program that causes anything to be printed on the screen. The other lines, like \#include <iostream> and int main(), are necessary for the framework of your program, but they do not cause any screen output. Remember, a program is a set of instructions for the computer. If something is to be displayed on the screen, you must use a programming statement for that purpose.

At the end of the line is a semicolon. Just as a period marks the end of a sentence, a semicolon marks the end of a complete statement in C++. Comments are ignored by the compiler, so the semicolon isn't required at the end of a comment. Preprocessor directives, like \#include statements, simply end at the end of the line and never require semicolons. The beginning of a function, like int main(), is not a complete statement, so you don't place a semicolon there either.

It might seem that the rules for where to put a semicolon are not clear at all. Rather than worry about it now, just concentrate on learning the parts of a program. You'll soon get a feel for where you should and should not use semicolons.

Line 8 reads:
return 0;
This sends the integer value 0 back to the operating system upon the program's completion. The value 0 usually indicates that a program executed successfully.
Line 9 contains the closing brace:

$$
\}
$$

This brace marks the end of the main function. Since main is the only function in this program, it also marks the end of the program.

In the sample program, you encountered several sets of special characters. Table 2-1 provides a short summary of how they were used.

Table 2-1 Special Characters
\(\left.$$
\begin{array}{lll}\hline \text { Character } & \text { Name } & \text { Description } \\
\hline \text { // } & \text { Double slash } & \text { Marks the beginning of a comment. } \\
\text { \# } & \text { Pound sign } & \text { Opening and closing brackets }\end{array}
$$ \begin{array}{l}Marks the beginning of a preprocessor directive. <br>
Enclose a filename when used with the <br>

\#include directive.\end{array}\right]\)| ( ) | Opening and closing parentheses | Used in naming a function, as in int main (). <br> \{ \} |
| :--- | :--- | :--- |
| Opening and closing braces | Enclose a group of statements, such as the con- <br> tents of a function. |  |
| ; Opening and closing quotation | Enclose a string of characters, such as a message <br> that is to be printed on the screen. |  |
|  | Semicolon | Marks the end of a complete programming <br> statement. |

## Checkpoint

2.1 The following C++ program will not compile because the lines have been mixed up.

```
int main()
}
// A crazy mixed up program
return 0;
```

```
#include <iostream>
cout << "In 1492 Columbus sailed the ocean blue.";
{
using namespace std;
```

When the lines are properly arranged, the program should display the following on the screen:

In 1492 Columbus sailed the ocean blue.
Rearrange the lines in the correct order. Test the program by entering it on the computer, compiling it, and running it.

### 2.2 The cout Object

CONCEPT: Use the cout object to display information on the computer's screen.
In this section, you will learn to write programs that produce output on the screen. The simplest type of screen output that a program can display is console output, which is merely plain text. The word console is an old computer term. It comes from the days when a computer operator interacted with the system by typing on a terminal. The terminal, which consisted of a simple screen and keyboard, was known as the console.
On modern computers, running graphical operating systems such as Windows or Mac OS X , console output is usually displayed in a window such as the one shown in Figure 2-1. In C++, you use the cout object to produce console output. (You can think of the word cout as meaning console output.)

Figure 2-1 A console window

cout is classified as a stream object, which means it works with streams of data. To print a message on the screen, you send a stream of characters to cout. Let's look at line 7 from Program 2-1:

```
cout << "Programming is great fun!";
```

Notice the << operator is used to send the string "Programming is great fun!" to cout. When the << symbol is used this way, it is called the stream insertion operator. The item immediately to the right of the operator is sent to cout then displayed on the screen.

The stream insertion operator is always written as two less-than signs with no space between them. Because you are using it to send a stream of data to the cout object, you can think of the stream insertion operator as an arrow that must point toward cout. This is illustrated in Figure 2-2.

Program 2-2 is another way to write the same program.
Figure 2-2 Think of $\ll$ as an arrow pointing to cout

```
cout << "Programming is great fun!";
Think of the stream insertion operator as an arrow that points toward cout.
cout « "Programming is great fun!";
```

## Program 2-2

```
// A simple C++ program
#include <iostream>
using namespace std;
int main()
{
    cout << "Programming is " << "great fun!";
    return 0;
}
```

## Program Output

Programming is great fun!
As you can see, the stream insertion operator can be used to send more than one item to cout. The output of this program is identical to that of Program 2-1. Program 2-3 shows yet another way to accomplish the same thing.

## Program 2-3

```
// A simple C++ program
#include <iostream>
using namespace std;
int main()
{
        cout << "Programming is ";
        cout << "great fun!";
        return 0;
}
```

## Program Output

Programming is great fun!

An important concept to understand about Program 2-3 is that, although the output is broken up into two programming statements, this program will still display the message on one line. Unless you specify otherwise, the information you send to cout is displayed in a continuous stream. Sometimes this can produce less-than-desirable results. Program 2-4 is an example.

The layout of the actual output looks nothing like the arrangement of the strings in the source code. First, notice there is no space displayed between the words "sellers" and "during," or between "June:" and "Computer." cout displays messages exactly as they are sent. If spaces are to be displayed, they must appear in the strings.

## Program 2-4

```
// An unruly printing program
#include <iostream>
using namespace std;
int main()
{
    cout << "The following items were top sellers";
    cout << "during the month of June:";
    cout << "Computer games";
    cout << "Coffee";
    cout << "Aspirin";
    return 0;
}
```

## Program Output

The following items were top sellersduring the month of June:Computer gamesCoffeeAspirin

Second, even though the output is broken into five lines in the source code, it comes out as one long line of output. Because the output is too long to fit on one line on the screen, it wraps around to a second line when displayed. The reason the output comes out as one long line is because cout does not start a new line unless told to do so. There are two ways to instruct cout to start a new line. The first is to send cout a stream manipulator called end 1 (which is pronounced "end-line" or "end-L"). Program 2-5 is an example.

## Program 2-5

```
// A well-adjusted printing program
#include <iostream>
using namespace std;
    int main()
    {
        cout << "The following items were top sellers" << endl;
        cout << "during the month of June:" << endl;
```

```
Program 2-5
(continued)
    9 cout << "Computer games" << end1;
10 cout << "Coffee" << endl;
11 cout << "Aspirin" << endl;
12 return 0;
13 }
```

## Program Output

The following items were top sellers during the month of June:
Computer games
Coffee
Aspirin

NOTE: The last character in end 1 is the lowercase letter L , not the number one.
Every time cout encounters an end1 stream manipulator, it advances the output position to the beginning of the next line for subsequent printing. The manipulator can be inserted anywhere in the stream of characters sent to cout, outside the double quotes. The following statements show an example.

```
cout << "My pets are" << endl << "dog";
cout << endl << "cat" << endl << "bird" << endl;
```

Another way to cause cout to go to a new line is to insert an escape sequence in the string itself. An escape sequence starts with the backslash character ( $\backslash$ ) and is followed by one or more control characters. It allows you to control the way output is displayed by embedding commands within the string itself. Program 2-6 is an example.

## Program 2-6

```
// Yet another well-adjusted printing program
#include <iostream>
using namespace std;
int main()
{
    cout << "The following items were top sellers\n";
    cout << "during the month of June:\n";
    cout << "Computer games\nCoffee";
    cout << "\nAspirin\n";
    return 0;
}
```

## Program Output

The following items were top sellers
during the month of June:
Computer games
Coffee
Aspirin

The newline escape sequence is $\backslash \mathrm{n}$. When cout encounters $\backslash \mathrm{n}$ in a string, it doesn't print it on the screen, but interprets it as a special command to advance the output cursor to the next line. You have probably noticed inserting the escape sequence requires less typing than inserting endl. That's why many programmers prefer it.

A common mistake made by beginning C++ students is to use a forward slash (/) instead of a backslash ( $\backslash$ ) when trying to write an escape sequence. This will not work. For example, look at the following code:

```
// Error!
cout << "Four Score/nAnd seven/nYears ago./n";
```

In this code, the programmer accidentally wrote / n when he or she meant to write n . The cout object will simply display the / n characters on the screen. This code will display the following output:

```
Four Score/nAnd seven/nYears ago./n
```

Another common mistake is to forget to put the In inside quotation marks. For example, the following code will not compile:

```
// Error! This code will not compile.
cout << "Good" << \n;
cout << "Morning" << \n;
```

This code will result in an error because the $\ \mathrm{n}$ sequences are not inside quotation marks. We can correct the code by placing the $\backslash n$ sequences inside the string literals, as shown here:

```
// This will work.
cout << "Good\n";
cout << "Morning\n";
```

There are many escape sequences in C++. They give you the ability to exercise greater control over the way information is output by your program. Table 2-2 lists a few of them.

Table 2-2 Common Escape Sequences

| Escape Sequence | Name | Description |
| :---: | :---: | :---: |
| 1 n | Newline | Causes the cursor to go to the next line for subsequent printing. |
| 1 t | Horizontal tab | Causes the cursor to skip over to the next tab stop. |
| la | Alarm | Causes the computer to beep. |
| lb | Backspace | Causes the cursor to back up, or move left one position. |
| Ir | Return | Causes the cursor to go to the beginning of the current line, not the next line. |
| 11 | Backslash | Causes a backslash to be printed. |
| $1 '$ | Single quote | Causes a single quotation mark to be printed. |
| \" | Double quote | Causes a double quotation mark to be printed. |

WARNING! When using escape sequences, do not put a space between the backslash and the control character.

When you type an escape sequence in a string, you type two characters (a backslash followed by another character). However, an escape sequence is stored in memory as a single character. For example, consider the following string literal:

$$
\text { "One \nTwo \nThree } \backslash n "
$$

The diagram in Figure 2-3 breaks this string into its individual characters. Notice how each of the $\ln$ escape sequences are considered one character.

Figure 2-3 Individual characters in a string

### 2.3 The \#inc 7 ude Directive

CONCEPT: The \#include directive causes the contents of another file to be inserted into the program.

Now is a good time to expand our discussion of the \#include directive. The following line has appeared near the top of every example program.

```
#include <iostream>
```

The header file iostream must be included in any program that uses the cout object. This is because cout is not part of the "core" of the C++ language. Specifically, it is part of the input-output stream library. The header file, iostream, contains information describing iostream objects. Without it, the compiler will not know how to properly compile a program that uses cout.
Preprocessor directives are not C++ statements. They are commands to the preprocessor, which runs prior to the compiler (hence the name "preprocessor"). The preprocessor's job is to set programs up in a way that makes life easier for the programmer.

For example, any program that uses the cout object must contain the extensive setup information found in iostream. The programmer could type all this information into the program, but it would be too time consuming. An alternative would be to use an editor to "cut and paste" the information into the program, but that would quickly become tiring as well. The solution is to let the preprocessor insert the contents of iostream automatically.

WARNING! Do not put semicolons at the end of processor directives. Because preprocessor directives are not $\mathrm{C}++$ statements, they do not require semicolons. In many cases, an error will result from a preprocessor directive terminated with a semicolon.

An \#include directive must always contain the name of a file. The preprocessor inserts the entire contents of the file into the program at the point it encounters the \#include directive.

The compiler doesn't actually see the \#include directive. Instead, it sees the code that was inserted by the preprocessor, just as if the programmer had typed it there.
The code contained in header files is C++ code. Typically, it describes complex objects like cout. Later, you will learn to create your own header files.

## Checkpoint

2.2 The following C++ program will not compile because the lines have been mixed up.

```
cout << "Success\n";
cout << " Success\n\n";
int main()
cout << "Success";
}
using namespace std;
// It's a mad, mad program
#include <iostream>
cout << "Success\n";
{
return 0;
```

When the lines are properly arranged, the program should display the following on the screen:

## Success

Success Success

## Success

Rearrange the lines in the correct order. Test the program by entering it on the computer, compiling it, and running it.
2.3 Study the following program and show what it will print on the screen:
// The Works of Wolfgang
\#include <iostream>
using namespace std;
int main()
\{

```
        cout << "The works of Wolfgang\ninclude the following";
```

        cout << "\nThe Turkish March" << endl;
        cout << "and Symphony No. 40 ";
        cout << "in G minor." << endl;
        return 0;
    \}
    2.4 Write a program that will display your name on the first line, your street address on the second line, your city, state, and ZIP code on the third line, and your telephone number on the fourth line. Place a comment with today's date at the top of the program. Test your program by compiling and running it.

### 2.4 Variables, Literals, and Assignment Statements

CONCEPT: Variables represent storage locations in the computer's memory. Literals are constant values that are assigned to variables.

As you discovered in Chapter 1, variables allow you to store and work with data in the computer's memory. They provide an "interface" to RAM. Part of the job of programming is to determine how many variables a program will need and what types of information they will hold. Program 2-7 is an example of a C++ program with a variable. Take a look at line 7:

```
int number;
```

This is called a variable definition. It tells the compiler the variable's name and the type of data it will hold. This line indicates the variable's name is number. The word int stands for integer, so number will only be used to hold integer numbers. Later in this chapter, you will learn all the types of data that $\mathrm{C}++$ allows.

## Program 2-7

```
// This program has a variable.
#include <iostream>
using namespace std;
int main()
{
        int number;
        number = 5;
        cout << "The value in number is " << number << endl;
        return 0;
}
```

## Program Output

The value in number is 5

NOTE: You must have a definition for every variable you intend to use in a program. In C++, variable definitions can appear at any point in the program. Later in this chapter, and throughout the book, you will learn the best places to define variables.

Notice variable definitions end with a semicolon. Now look at line 9:

```
    number = 5;
```

This is called an assignment. The equal sign is an operator that copies the value on its right (5) into the variable named on its left (number). After this line executes, number will be set to 5 .

NOTE: This line does not print anything on the computer's screen. It runs silently behind the scenes, storing a value in RAM.

Look at line 10 :

```
cout << "The value in number is " << number << endl;
```

The second item sent to cout is the variable name number. When you send a variable name to cout, it prints the variable's contents. Notice there are no quotation marks around number. Look at what happens in Program 2-8.

## Program 2-8

```
    // This program has a variable.
```

    \#include <iostream>
    using namespace std;
    int main()
    \{
        int number;
    number \(=5\);
    cout << "The value in number is " << "number" << endl;
    return 0;
    \}

## Program Output

The value in number is number

When double quotation marks are placed around the word number, it becomes a string literal and is no longer a variable name. When string literals are sent to cout, they are printed exactly as they appear inside the quotation marks. You've probably noticed by now that the end 1 stream manipulator has no quotation marks around it, for the same reason.

## Sometimes a Number Isn't a Number

As shown in Program 2-8, just placing quotation marks around a variable name changes the program's results. In fact, placing double quotation marks around anything that is not intended to be a string literal will create an error of some type. For example, in Program $2-8$, the number 5 was assigned to the variable number. It would have been incorrect to perform the assignment this way:

```
number = "5";
```

In this line, 5 is no longer an integer, but a string literal. Because number was defined as an integer variable, you can only store integers in it. The integer 5 and the string literal " 5 " are not the same thing.

The fact that numbers can be represented as strings frequently confuses students who are new to programming. Just remember that strings are intended for humans to read. They are to be printed on computer screens or paper. Numbers, however, are intended primarily for mathematical operations. You cannot perform math on strings. Before numbers can be displayed on the screen, they must first be converted to strings. (Fortunately, cout handles the conversion automatically when you send a number to it.)

## Literals

A literal is a piece of data that is written directly into a program's code. One of the most common uses of literals is to assign a value to a variable. For example, in the following statement, assume number is an int variable. The statement assigns the literal value 100 to the variable number.

```
number = 100;
```

Another common use of literals is to display something on the screen. For example, the following statement displays the string literal "Welcome to my program."

```
cout << "Welcome to my program." << endl;
```

Program 2-9 shows an example that uses a variable and several literals.

## Program 2-9

```
// This program has literals and a variable.
#include <iostream>
using namespace std;
int main()
{
        int apples;
        apples = 20;
        cout << "Today we sold " << apples << " bushels of apples.\n";
        return 0;
}
```

## Program Output

Today we sold 20 bushels of apples.

Of course, the variable is apples. It is defined as an integer. Table 2-3 lists the literals found in the program.

Table 2-3 Literals and Their Types

| Literal | Type of Literal |
| :--- | :--- |
| 20 | Integer literal |
| "Today we sold" | String literal |
| "bushels of apples. $\ln "$ | String literal |
| 0 | Integer literal |

NOTE: Literals are also called constants.

## (1) Checkpoint

2.5 Examine the following program:

```
// This program uses variables and literals.
#include <iostream>
using namespace std;
int main()
{
    int little;
    int big;
    little = 2;
    big = 2000;
    cout << "The little number is " << little << endl;
    cout << "The big number is " << big << endl;
    return 0;
}
```

List all the variables and literals that appear in the program.
2.6 What will the following program display on the screen?

```
#include <iostream>
using namespace std;
int main()
{
        int number;
        number = 712;
        cout << "The value is " << "number" << endl;
        return 0;
}
```

### 2.5 Identifiers

CONCEPT: Choose variable names that indicate what the variables are used for.
An identifier is a programmer-defined name that represents some element of a program. Variable names are examples of identifiers. You may choose your own variable names in $\mathrm{C}++$, as long as you do not use any of the C++ key words. The key words make up the "core" of the language and have specific purposes. Table 2-4 shows a complete list of the C++ key words. Note they are all lowercase.

Table 2-4 The C++ Key Words

| alignas | const | for | private | throw |
| :--- | :--- | :--- | :--- | :--- |
| alignof | constexpr | friend | protected | true |
| and | const_cast | goto | public | try |
| and_eq | continue | if | register | typedef |
| asm | decltype | inline | reinterpret_cast | typeid |
| auto | default | int | return | typename |
| bitand | delete | dong | short | union |
| bitor | double | dynamic_cast | new | namespace |
| bool | else | sizeof | unsigned |  |
| break | enum | noexcept | static_assert | using |
| case | explicit | not_eq | static_cast | volatile |
| catch | export | nul1ptr | switch | wchar_t |
| char | extern | false | operator | template |

You should always choose names for your variables that give an indication of what the variables are used for. You may be tempted to define variables with names like this:

```
int x;
```

The rather nondescript name, $x$, gives no clue as to the variable's purpose. Here is a better example.

```
int itemsOrdered;
```

The name itemsOrdered gives anyone reading the program an idea of the variable's use. This way of coding helps produce self-documenting programs, which means you get an understanding of what the program is doing just by reading its code. Because real-world programs usually have thousands of lines, it is important that they be as self-documenting as possible.

You probably have noticed the mixture of uppercase and lowercase letters in the name itemsOrdered. Although all of C++'s key words must be written in lowercase, you may use uppercase letters in variable names.

The reason the 0 in itemsOrdered is capitalized is to improve readability. Normally "items ordered" is two words. Unfortunately, you cannot have spaces in a variable name, so the two words must be combined into one. When "items" and "ordered" are stuck together, you get a variable definition like this:
int itemsordered;
Capitalization of the first letter of the second word and succeeding words makes itemsOrdered easier to read. It should be mentioned that this style of coding is not required. You are free to use all lowercase letters, all uppercase letters, or any combination of both. In fact, some programmers use the underscore character to separate words in a variable name, as in the following.
int items_ordered;

## Legal Identifiers

Regardless of which style you adopt, be consistent and make your variable names as sensible as possible. Here are some specific rules that must be followed with all identifiers.

- The first character must be one of the letters a through $z, A$ through $Z$, or an underscore character (_).
- After the first character you may use the letters a through z or A through Z, the digits 0 through 9 , or underscores.
- Uppercase and lowercase characters are distinct. This means ItemsOrdered is not the same as itemsordered.

Table 2-5 lists variable names and tells whether each is legal or illegal in C++.

Table 2-5 Some Variable Names

| Variable Name | Legal or Illegal? |
| :--- | :--- |
| dayOfWeek | Legal. |
| 3dGraph | Illegal. Variable names cannot begin with a digit. |
| _employee_num | Legal. |
| June1997 | Legal. |
| Mixture\#3 | Illegal. Variable names may only use letters, digits, or underscores. |

### 2.6 Integer Data Types

CONCEPT: There are many different types of data. Variables are classified according to their data type, which determines the kind of information that may be stored in them. Integer variables can only hold whole numbers.

Computer programs collect pieces of data from the real world and manipulate them in various ways. There are many different types of data. In the realm of numeric information, for example, there are whole numbers and fractional numbers. There are negative numbers and positive numbers. And there are numbers so large, and others so small, they don't even have a name. Then there is textual information. Names and addresses, for instance, are stored as groups of characters. When you write a program, you must determine what types of information it will be likely to encounter.
If you are writing a program to calculate the number of miles to a distant star, you'll need variables that can hold very large numbers. If you are designing software to record microscopic dimensions, you'll need to store very small and precise numbers. Additionally, if you are writing a program that must perform thousands of intensive calculations, you'll want variables that can be processed quickly. The data type of a variable determines all of these factors.

Although C++ offers many data types, in the very broadest sense there are only two: numeric and character. Numeric data types are broken into two additional categories: integer and floating point. Integers are whole numbers like 12, 157, -34 , and 2 . Floating-point numbers have a decimal point, like 23.7, 189.0231, and 0.987. Additionally, the integer and floating-point data types are broken into even more classifications. Before we discuss the character data type, let's carefully examine the variations of numeric data.

Your primary considerations for selecting a numeric data type are

- The largest and smallest numbers that may be stored in the variable
- How much memory the variable uses
- Whether the variable stores signed or unsigned numbers
- The number of decimal places of precision the variable has

The size of a variable is the number of bytes of memory it uses. Typically, the larger a variable is, the greater the range it can hold.

Table 2-6 shows the C++ integer data types with their typical sizes and ranges.

NOTE: The data type sizes and ranges shown in Table 2-6 are typical on many systems. Depending on your operating system, the sizes and ranges may be different.

Table 2-6 Integer Data Types

| Data Type | Typical Size | Typical Range |
| :--- | :---: | :--- |
| short int | 2 bytes | $-32,768$ to $+32,767$ |
| unsigned short int | 2 bytes | 0 to $+65,535$ |
| int | 4 bytes | $-2,147,483,648$ to $+2,147,483,647$ |
| unsigned int | 4 bytes | 0 to 4,294,967,295 |
| long int | 4 bytes | $-2,147,483,648$ to $+2,147,483,647$ |
| unsigned long int | 4 bytes | 0 to 4,294,967,295 |
| long long int | 8 bytes | $-9,223,372,036,854,775,808$ to |
|  |  | 9 bytes |
| unsigned long long int |  | 0 to $18,446,744,073,709,551,615$ |

Here are some examples of variable definitions:

```
int days;
unsigned int speed;
short int month;
unsigned short int amount;
long int deficit;
unsigned long int insects;
```

Each of the data types in Table 2-6, except int, can be abbreviated as follows:

- short int can be abbreviated as short
- unsigned short int can be abbreviated as unsigned short
- unsigned int can be abbreviated as unsigned
- long int can be abbreviated as long
- unsigned long int can be abbreviated as unsigned long
- long long int can be abbreviated as long long
- unsigned long long int can be abbreviated as unsigned long long

Because they simplify definition statements, programmers commonly use the abbreviated data type names. Here are some examples:

```
unsigned speed;
short month;
unsigned short amount;
long deficit;
unsigned long insects;
long long grandTotal;
unsigned long long lightYearDistance;
```

Unsigned data types can only store nonnegative values. They can be used when you know your program will not encounter negative values. For example, variables that hold ages or weights would rarely hold numbers less than 0 .
Notice in Table 2-6 the int and long data types have the same sizes and ranges, and that the unsigned int data type has the same size and range as the unsigned long data type. This is not always true because the size of integers is dependent on the type of system you are using. Here are the only guarantees:

- Integers are at least as big as short integers.
- Long integers are at least as big as integers.
- Unsigned short integers are the same size as short integers.
- Unsigned integers are the same size as integers.
- Unsigned long integers are the same size as long integers.
- The long long int and the unsigned long long int data types are guaranteed to be at least 8 bytes ( 64 bits) in size.

Later in this chapter, you will learn to use the sizeof operator to determine how large all the data types are on your computer.

NOTE: The long long int and the unsigned long long int data types were introduced in C++ 11.

As mentioned before, variables are defined by stating the data type key word followed by the name of the variable. In Program 2-10, an integer, an unsigned integer, and a long integer have been defined.

## Program 2-10

```
// This program has variables of several of the integer types.
#include <iostream>
using namespace std;
int main()
{
    int checking;
    unsigned int miles;
    long days;
    checking = -20;
    miles = 4276;
    diameter = 100000;
    cout << "We have made a long journey of " << miles;
    cout << " miles.\n";
    cout << "Our checking account balance is " << checking;
    cout << "\nThe galaxy is about " << diameter;
    cout << " light years in diameter.\n";
    return 0;
}
```

## Program Output

We have made a long journey of 4276 miles.
Our checking account balance is -20
The galaxy is about 100000 light years in diameter.

In most programs, you will need more than one variable of any given data type. If a program uses two integers, length and width, they could be defined separately, like this:

```
int length;
int width;
```

It is easier, however, to combine both variable definitions on one line:
int length, width;
You can define several variables of the same type like this, simply by separating their names with commas. Program 2-11 illustrates this.

## Program 2-11

// This program shows three variables defined on the same line.
\#include <iostream>
using namespace std;

```
int main()
{
    int floors, rooms, suites;
    floors = 15;
    rooms = 300;
    suites = 30;
    cout << "The Grande Hotel has " << floors << " floors\n";
    cout << "with " << rooms << " rooms and " << suites;
    cout << " suites.\n";
    return 0;
}
```

## Program Output

The Grande Hotel has 15 floors
with 300 rooms and 30 suites.

## Integer and Long Integer Literals

In C++, if a numeric literal is an integer (not written with a decimal point) and it fits within the range of an int (see Table 2-6 for the minimum and maximum values), then the numeric literal is treated as an int. A numeric literal that is treated as an int is called an integer literal. For example, look at lines 9, 10, and 11 in Program 2-11:

```
floors = 15;
rooms = 300;
suites = 30;
```

Each of these statements assigns an integer literal to a variable.
One of the pleasing characteristics of the C++ language is that it allows you to control almost every aspect of your program. If you need to change the way something is stored in memory, the tools are provided to do that. For example, what if you are in a situation where you have an integer literal, but you need it to be stored in memory as a long integer? (Rest assured, this is a situation that does arise.) C++ allows you to force an integer literal to be stored as a long integer by placing the letter L at the end of the number. Here is an example:

```
long amount;
amount = 32L;
```

The first statement defines a long variable named amount. The second statement assigns the literal value 32 to the amount variable. In the second statement, the literal is written as 32 L , which makes it a long integer literal. This means the literal is treated as a long.

If you want an integer literal to be treated as a long long int, you can append LL at the end of the number. Here is an example:

```
long long amount;
amount = 32LL;
```

The first statement defines a long long variable named amount. The second statement assigns the literal value 32 to the amount variable. In the second statement, the literal is written as 32 LL , which makes it a long long integer literal. This means the literal is treated as a long long int.

TIP: When writing long integer literals or long long integer literals, you can use either an uppercase or a lowercase L. Because the lowercase 1 looks like the number 1, you should always use the uppercase L.

## If You Plan to Continue in Computer Science: Hexadecimal and Octal Literals

Programmers commonly express values in numbering systems other than decimal (or base 10 ). Hexadecimal (base 16) and octal (base 8 ) are popular because they make certain programming tasks more convenient than decimal numbers do.

By default, C++ assumes that all integer literals are expressed in decimal. You express hexadecimal numbers by placing 0 x in front of them. (This is zero- x , not oh-x.) Here is how the hexadecimal number F4 would be expressed in C++:

0xF4
Octal numbers must be preceded by a 0 (zero, not oh). For example, the octal 31 would be written

031

NOTE: You will not be writing programs for some time that require this type of manipulation. It is important, however, that you understand this material. Good programmers should develop the skills for reading other people's source code. You may find yourself reading programs that use items like long integer, hexadecimal, or octal literals.

## Checkpoint

2.7 Which of the following are illegal variable names, and why?

X
99bottles
july97
theSalesFigureForFiscalYear98
r\&d
grade_report
2.8 Is the variable name Sales the same as sales? Why or why not?
2.9 Refer to the data types listed in Table 2-6 for these questions.
A) If a variable needs to hold numbers in the range 32 to 6,000 , what data type would be best?
B) If a variable needs to hold numbers in the range 240,000 to 140,000 , what data type would be best?
C) Which of the following literals uses more memory? 20 or 20 L
2.10 On any computer, which data type uses more memory, an integer or an unsigned integer?

### 2.7 The char Data Type

The char data type is used to store individual characters. A variable of the char data type can hold only one character at a time. Here is an example of how you might declare a char variable:

```
char letter;
```

This statement declares a char variable named letter, which can store one character. In C++, character literals are enclosed in single quotation marks. Here is an example showing how we would assign a character to the letter variable:

```
letter = 'g';
```

This statement assigns the character ' $g$ ' to the letter variable. Because char variables can hold only one character, they are not compatible with strings. For example, you cannot assign a string to a char variable, even if the string contains only one character. The following statement, for example, will not compile because it attempts to assign a string literal to a char variable.

```
letter = "g"; // ERROR! Cannot assign a string to a char
```

It is important that you do not confuse character literals, which are enclosed in single quotation marks, with string literals, which are enclosed in double quotation marks.

Program 2-12 shows an example program that works with characters.

## Program 2-12

```
// This program works with characters.
#include <iostream>
using namespace std;
int main()
{
        char letter;
        letter = 'A';
        cout << letter << endl;
        letter = 'B';
        cout << letter << endl;
        return 0;
}
```

## Program Output

A
B

Although the char data type is used for storing characters, it is actually an integer data type that typically uses 1 byte of memory. (The size is system dependent. On some systems, the char data type is larger than 1 byte.)

The reason an integer data type is used to store characters is because characters are internally represented by numbers. Each printable character, as well as many nonprintable characters, is assigned a unique number. The most commonly used method for encoding characters is ASCII, which stands for the American Standard Code for Information Interchange. (There are other codes, such as EBCDIC, which is used by many IBM mainframes.)
When a character is stored in memory, it is actually the numeric code that is stored. When the computer is instructed to print the value on the screen, it displays the character that corresponds with the numeric code.

You may want to refer to Appendix A, which shows the ASCII character set. Notice the number 65 is the code for A, 66 is the code for B, and so on. Program 2-13 demonstrates that when you work with characters, you are actually working with numbers.

## Program 2-13

```
// This program demonstrates the close relationship between
// characters and integers.
#include <iostream>
using namespace std;
int main()
{
    char letter;
    letter = 65;
    cout << letter << endl;
    letter = 66;
    cout << letter << endl;
    return 0;
}
```

## Program Output

A
B

Figure 2-4 illustrates that when characters, such as A, B, and C, are stored in memory, it is really the numbers 65,66 , and 67 that are stored.

## The Difference between String Literals and Character Literals

It is important that you do not confuse character literals with string literals. Strings, which are a series of characters stored in consecutive memory locations, can be virtually any

Figure 2-4 Characters and their ASCII codes

length. This means that there must be some way for the program to know how long a string is. In C++, an extra byte is appended to the end of string literals when they are stored in memory. In this last byte, the number 0 is stored. It is called the null terminator or null character, and it marks the end of the string.

Don't confuse the null terminator with the character ' 0 '. If you look at Appendix A, you will see that ASCII code 48 corresponds to the character ' 0 ', whereas the null terminator is the same as the ASCII code 0 . If you want to print the character 0 on the screen, you use ASCII code 48. If you want to mark the end of a string, however, you use ASCII code 0 .

Let's look at an example of how a string literal is stored in memory. Figure 2-5 depicts the way the string literal "Sebastian" would be stored.

Figure 2-5 The string literal "Sebastian"

| S | e | b | a | s | t | i | a | n | 10 |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

First, notice the quotation marks are not stored with the string. They are simply a way of marking the beginning and end of the string in your source code. Second, notice the very last byte of the string. It contains the null terminator, which is represented by the 10 character. The addition of this last byte means that although the string "Sebastian" is 9 characters long, it occupies 10 bytes of memory.

The null terminator is another example of something that sits quietly in the background. It doesn't print on the screen when you display a string, but nevertheless, it is there silently doing its job.

NOTE: C++ automatically places the null terminator at the end of string literals.

Now let's compare the way a string and a char are stored. Suppose you have the literals 'A' and "A" in a program. Figure 2-6 depicts their internal storage.

As you can see, ' A ' is a 1 -byte element and " A " is a 2 -byte element. Since characters are really stored as ASCII codes, Figure 2-7 shows what is actually being stored in memory.

Figure 2-6 ' A ' as a character and " A " as a string

Figure 2-7 ASCII codes
' A ' is stored as
" A " is stored as
65
0

Because char variables are only large enough to hold one character, you cannot assign string literals to them. For example, the following code defines a char variable named letter. The character literal 'A' can be assigned to the variable, but the string literal "A" cannot.

```
char letter;
letter = 'A'; // This will work.
letter = "A"; // This will not work!
```

One final topic about characters should be discussed. You have learned that some strings look like a single character but really aren't. It is also possible to have a character that looks like a string. A good example is the newline character, n . Although it is represented by two characters, a slash and an $n$, it is internally represented as one character. In fact, all escape sequences, internally, are just 1 byte.
Program 2-14 shows the use of $\backslash \mathrm{n}$ as a character literal, enclosed in single quotation marks. If you refer to the ASCII chart in Appendix A, you will see that ASCII code 10 is the linefeed character. This is the code C++ uses for the newline character.

## Program 2-14

```
// This program uses character literals.
#include <iostream>
using namespace std;
int main()
{
    char letter;
    letter = 'A';
    cout << letter << '\n';
    letter = 'B';
```

```
12 cout << letter << '\n';
13 return 0;
14 }
```

## Program Output

A
B

Let's review some important points regarding characters and strings:

- Printable characters are internally represented by numeric codes. Most computers use ASCII codes for this purpose.
- Characters normally occupy a single byte of memory.
- Strings are consecutive sequences of characters that occupy consecutive bytes of memory.
- String literals are always stored in memory with a null terminator at the end. This marks the end of the string.
- Character literals are enclosed in single quotation marks.
- String literals are enclosed in double quotation marks.
- Escape sequences such as ' $\backslash \mathrm{n}$ ' are stored internally as a single character.

### 2.8 The C++ string Class

CONCEPT: Standard C++ provides a special data type for storing and working with strings.

Because a char variable can store only one character in its memory location, another data type is needed for a variable able to hold an entire string. Although C++ does not have a built-in data type able to do this, standard $\mathrm{C}++$ provides something called the string class that allows the programmer to create a string type variable.

## Using the string Class

The first step in using the string class is to \#include the <string> header file. This is accomplished with the following preprocessor directive:

```
#include <string>
```

The next step is to define a string type variable, called a string object. Defining a string object is similar to defining a variable of a primitive type. For example, the following statement defines a string object named movieTitle.

```
string movieTitle;
```

You can assign a string literal to movieTitle with the assignment operator:

```
movieTitle = "Wheels of Fury";
```

You can use cout to display the value of the movieTitle object, as shown in the next statement:

```
cout << "My favorite movie is " << movieTitle << endl;
```

Program 2-15 is a complete program that demonstrates the preceding statements.

## Program 2-15

```
// This program demonstrates the string class.
#include <iostream>
#include <string> // Required for the string class.
using namespace std;
int main()
{
    string movieTitle;
    movieTitle = "Wheels of Fury";
    cout << "My favorite movie is " << movieTitle << endl;
    return 0;
}
```

## Program Output

My favorite movie is Wheels of Fury

As you can see, working with string objects is similar to working with variables of other types. Throughout this text, we will continue to discuss string class features and capabilities.

## Checkpoint

2.11 What are the ASCII codes for the following characters? (Refer to Appendix A.)

C
F
W
2.12 Which of the following is a character literal?
'B'
"B"
2.13 Assuming the char data type uses 1 byte of memory, how many bytes do the following literals use?
'Q'
"Q"
"Sales"
' In '
2.14 Write a program that has the following character variables: first, middle, and last. Store your initials in these variables then display them on the screen.
2.15 What is wrong with the following program statement?
char letter = "Z";
2.16 What header file must you include in order to use string objects?
2.17 Write a program that stores your name, address, and phone number in three separate string objects. Display the contents of the string objects on the screen.

### 2.9 Floating-Point Data Types

CONCEPT: Floating-point data types are used to define variables that can hold real numbers.

Whole numbers are not adequate for many jobs. If you are writing a program that works with dollar amounts or precise measurements, you need a data type that allows fractional values. In programming terms, these are called floating-point numbers.
Internally, floating-point numbers are stored in a manner similar to scientific notation. Take the number $47,281.97$. In scientific notation, this number is $4.728197 \times 10^{4} .\left(10^{4}\right.$ is equal to 10,000 , and $4.728197 \times 10,000$ is $47,281.97$.) The first part of the number, 4.728197, is called the mantissa. The mantissa is multiplied by a power of 10 .

Computers typically use E notation to represent floating-point values. In E notation, the number $47,281.97$ would be 4.728197 E 4 . The part of the number before the E is the mantissa, and the part after the E is the power of 10 . When a floating-point number is stored in memory, it is stored as the mantissa and the power of 10.

Table 2-7 shows other numbers represented in scientific and E notation.
Table 2-7 Floating-Point Representations

| Decimal Notation | Scientific Notation | E Notation |
| :--- | :--- | :--- |
| 247.91 | $2.4791 \times 10^{2}$ | 2.4791 E 2 |
| 0.00072 | $7.2 \times 10^{-4}$ | $7.2 \mathrm{E}-4$ |
| $2,900,000$ | $2.9 \times 10^{6}$ | 2.9 E 6 |

In C++, there are three data types that can represent floating-point numbers. They are

```
float
double
    long double
```

The float data type is considered single precision. The double data type is usually twice as big as float, so it is considered double precision. As you've probably guessed, the long double is intended to be larger than the double. Of course, the exact sizes of these data types are dependent on the computer you are using. The only guarantees are

- A double is at least as big as a float.
- A long double is at least as big as a double.

Table 2-8 shows the typical sizes and ranges of floating-point data types.
Table 2-8 Floating-Point Data Types on PCs

| Data Type | Key Word | Description |
| :--- | :--- | :--- |
| Single precision | float | 4 bytes. Numbers between $\pm 3.4 \mathrm{E}-38$ and $\pm 3.4 \mathrm{E} 38$ |
| Double precision | double | 8 bytes. Numbers between $\pm 1.7 \mathrm{E}-308$ and $\pm 1.7 \mathrm{E} 308$ |
| Long double precision | long double | 8 bytes*. Numbers between $\pm 1.7 \mathrm{E}-308$ and $\pm 1.7 \mathrm{E} 308$ |

[^0]You will notice there are no unsigned floating-point data types. On all machines, variables of the float, double, and long double data types can store positive or negative numbers.

## Floating-Point Literals

Floating-point literals may be expressed in a variety of ways. As shown in Program 2-16, E notation is one method. When you are writing numbers that are extremely large or extremely small, this will probably be the easiest way. E notation numbers may be expressed with an uppercase E or a lowercase e. Notice in the source code, the literals were written as 1.495979 E 11 and 1.989 E 30 , but the program printed them as $1.49598 \mathrm{e}+011$ and $1.989 \mathrm{e}+30$. The two sets of numbers are equivalent. (The plus sign in front of the exponent is also optional.) In Chapter 3 , you will learn to control the way cout displays E notation numbers.

## Program 2-16

```
// This program uses floating-point data types.
#include <iostream>
using namespace std;
int main()
{
    float distance;
    double mass;
    distance = 1.495979E11;
    mass = 1.989E30;
    cout << "The Sun is " << distance << " meters away.\n";
    cout << "The Sun\'s mass is " << mass << " kilograms.\n";
    return 0;
}
```

## Program Output

The Sun is $1.49598 \mathrm{e}+011$ meters away.
The Sun's mass is $1.989 \mathrm{e}+030$ kilograms.

You can also express floating-point literals in decimal notation. The literal 1.495979E11 could have been written as:
149597900000.00

Obviously the E notation is more convenient for lengthy numbers, but for numbers like 47.39 , decimal notation is preferable to 4.739 E 1 .

All of the following floating-point literals are equivalent:
1.4959E11
1.4959 e 11

1. $4959 \mathrm{E}+11$
$1.4959 \mathrm{e}+11$
149590000000.00

Floating-point literals are normally stored in memory as doubles. But remember, C++ provides tools for handling just about any situation. Just in case you need to force a literal to be stored as a float, you can append the letter F or f to the end of it. For example, the following literals would be stored as floats:
1.2F
$45.907 f$

NOTE: Because floating-point literals are normally stored in memory as doubles, most compilers issue a warning message when you assign a floating-point literal to a float variable. For example, assuming num is a float, the following statement might cause the compiler to generate a warning message:

```
num = 14.725;
```

You can suppress the warning message by appending the $f$ suffix to the floating-point literal, as shown below:

```
num = 14.725f;
```

If you want to force a value to be stored as a long double, append an $L$ or 1 to it, as in the following examples:
1034.56L
89.21

The compiler won't confuse these with long integers because they have decimal points. (Remember, the lowercase L looks so much like the number 1 that you should always use the uppercase $L$ when suffixing literals.)

## Assigning Floating-Point Values to Integer Variables

When a floating-point value is assigned to an integer variable, the fractional part of the value (the part after the decimal point) is discarded. For example, look at the following code:

```
int number;
number = 7.5; // Assigns 7 to number
```

This code attempts to assign the floating-point value 7.5 to the integer variable number. As a result, the value 7 will be assigned to number, with the fractional part discarded. When part of a value is discarded, it is said to be truncated.
Assigning a floating-point variable to an integer variable has the same effect. For example, look at the following code:

```
int i;
float f;
f = 7.5;
i = f; // Assigns 7 to i.
```

When the $f$ loat variable $f$ is assigned to the int variable $i$, the value being assigned (7.5) is truncated. After this code executes, i will hold the value 7 and f will hold the value 7.5 .

NOTE: When a floating-point value is truncated, it is not rounded. Assigning the value 7.9 to an int variable will result in the value 7 being stored in the variable.

WARNING! Floating-point variables can hold a much larger range of values than integer variables can. If a floating-point value is being stored in an integer variable, and the whole part of the value (the part before the decimal point) is too large for the integer variable, an invalid value will be stored in the integer variable.

### 2.10 The boo1 Data Type

CONCEPT: Boolean variables are set to either true or false.
Expressions that have a true or false value are called Boolean expressions, named in honor of English mathematician George Boole (1815-1864).

The bool data type allows you to create small integer variables that are suitable for holding true or false values. Program 2-17 demonstrates the definition and assignment of a bool variable.

## Program 2-17

```
// This program demonstrates boolean variables.
#include <iostream>
using namespace std;
int main()
{
    bool boolValue;
        boolValue = true;
        cout << boolValue << endl;
        boolValue = false;
        cout << boolValue << endl;
        return 0;
}
```

## Program Output

1
0
As you can see from the program output, the value true is represented in memory by the number 1 , and false is represented by 0 . You will not be using bool variables until Chapter 4, however, so just remember they are useful for evaluating conditions that are either true or false.

### 2.11 Determining the Size of a Data Type

CONCEPT: The sizeof operator may be used to determine the size of a data type on any system.

Chapter 1 discussed the portability of the C++ language. As you have seen in this chapter, one of the problems of portability is the lack of common sizes of data types on all machines. If you are not sure what the sizes of data types are on your computer, C++ provides a way to find out.

A special operator called sizeof will report the number of bytes of memory used by any data type or variable. Program 2-18 illustrates its use. The first line that uses the operator is line 10 :

```
cout << "The size of an integer is " << sizeof(int);
```

The name of the data type or variable is placed inside the parentheses that follow the operator. The operator "returns" the number of bytes used by that item. This operator can be invoked anywhere you can use an unsigned integer, including in mathematical operations.

## Program 2-18

```
// This program determines the size of integers, long
// integers, and long doubles.
#include <iostream>
using namespace std;
int main()
{
    long double apple;
    cout << "The size of an integer is " << sizeof(int);
    cout << " bytes.\n";
    cout << "The size of a long integer is " << sizeof(long);
    cout << " bytes.\n";
    cout << "An apple can be eaten in " << sizeof(apple);
    cout << " bytes!\n";
    return 0;
}
```

## Program Output

The size of an integer is 4 bytes.
The size of a long integer is 4 bytes.
An apple can be eaten in 8 bytes!

## (1)

## Checkpoint

2.18 Yes or No: Is there an unsigned floating-point data type? If so, what is it?
2.19 How would the following number in scientific notation be represented in E notation?

$$
6.31 \times 10^{17}
$$

2.20 Write a program that defines an integer variable named age and a float variable named weight. Store your age and weight, as literals, in the variables. The program should display these values on the screen in a manner similar to the following:

My age is 26 and my weight is 180 pounds.
(Feel free to lie to the computer about your age and your weight-it'll never know!)

### 2.12 More about Variable Assignments and Initialization

CONCEPT: An assignment operation assigns, or copies, a value into a variable. When a value is assigned to a variable as part of the variable's definition, it is called an initialization.

As you have already seen in several examples, a value is stored in a variable with an assignment statement. For example, the following statement copies the value 12 into the variable unitsSold:

```
unitsSold = 12;
```

The $=$ symbol is called the assignment operator. Operators perform operations on data. The data that operators work with are called operands. The assignment operator has two operands. In the previous statement, the operands are unitsSold and 12.

In an assignment statement, C++ requires the name of the variable receiving the assignment to appear on the left side of the operator. The following statement is incorrect:

```
12 = unitsSold; // Incorrect!
```

In C++ terminology, the operand on the left side of the $=$ symbol must be an lvalue. It is called an lvalue because it is a value that may appear on the left side of an assignment operator. An lvalue is something that identifies a place in memory whose contents may be changed. Most of the time this will be a variable name. The operand on the right side of the $=$ symbol must be an rualue. An rvalue is any expression that has a value. The assignment statement takes the value of the rvalue and puts it in the memory location of the object identified by the lvalue.

You may also assign values to variables as part of the definition. This is called initialization. Program 2-19 shows how it is done.

## Program 2-19

```
// This program shows variable initialization.
#include <iostream>
using namespace std;
int main()
{
        int month = 2, days = 28;
        cout << "Month " << month << " has " << days << " days.\n";
        return 0;
}
```

## Program Output

Month 2 has 28 days.

As you can see, this simplifies the program and reduces the number of statements that must be typed by the programmer. Here are examples of other definition statements that perform initialization:

```
double interestRate = 12.9;
char stockCode = 'D';
1ong customerNum = 459L;
```

Of course, there are always variations on a theme. C++ allows you to define several variables and only initialize some of them. Here is an example of such a definition:

```
int flightNum = 89, travelTime, departure = 10, distance;
```

The variable flightNum is initialized to 89 and departure is initialized to 10 . The variables travelTime and distance remain uninitialized.

## Declaring Variables with the auto Key Word

C++ 11 introduces an alternative way to define variables, using the auto key word and an initialization value. Here is an example:

```
auto amount = 100;
```

Notice this statement uses the word auto instead of a data type. The auto key word tells the compiler to determine the variable's data type from the initialization value. In this example, the initialization value, 100 , is an int, so amount will be an int variable. Here are other examples:

```
auto interestRate = 12.0;
auto stockCode = 'D';
auto customerNum = 459L;
```

In this code, the interestRate variable will be a double because the initialization value, 12.0 , is a double. The stockCode variable will be a char because the initialization value,
' D ', is a char. The customerNum variable will be a long because the initialization value, 459 L , is a long.

These examples show how to use the auto key word, but they don't really show its usefulness. The auto key word is intended to simplify the syntax of declarations that are more complex than the ones shown here. Later in the book, you will see examples of how the auto key word can improve the readability of complex definition statements.

## Alternative Forms of Variable Initialization

The most common way to initialize a variable is to use the assignment operator in the variable definition statement, as shown here:

```
int value = 5;
```

However, there are two alternative techniques for initializing variables. The first is to enclose the initialization value in a set of parentheses, just after the variable name. Here is how you would define the value variable and initialize it to 5 using this technique:

```
int value(5);
```

The second alternative, introduced in C++ 11, is to enclose the initialization value in a set of curly braces, just after the variable name. Here is how you would define the value variable and initialize it to 5 using the brace notation:

```
int value {5}; // This only works with C++ 11 or higher.
```

Most programmers continue to use the assignment operator to initialize regular variables, as we do throughout this book. However, the brace notation offers an advantage. It checks to make sure the value you are initializing the variable with matches the data type of the variable. For example, assume that doubleVal is a double variable with 6.2 stored in it. Using the assignment operator, it is possible to write either of the following statements:

```
int value1 = 4.9; // This will store 4 in value1
int value2 = doubleVal; // This will store 6 in value2
```

In both cases, the fractional part of the value will be truncated before it is assigned to the variable being defined. This could cause problems, yet C++ compilers allow it. They do issue a warning, but they still build an executable file you can run. If the brace notation is used, however, the compiler indicates that these statements produce an error, and no executable is created. You will have to fix the errors and rebuild the project before you can run the program.

### 2.13 Scope

CONCEPT: A variable's scope is the part of the program that has access to the variable.

Every variable has a scope. The scope of a variable is the part of the program where the variable may be used. The rules that define a variable's scope are complex, and you will
only be introduced to the concept here. In other sections of the book, we will revisit this topic and expand on it.
The first rule of scope you should learn is that a variable cannot be used in any part of the program before the definition. Program 2-20 illustrates this.

## Program 2-20

```
// This program can't find its variable.
#include <iostream>
using namespace std;
int main()
{
        cout << value; // ERROR! value not defined yet!
        int value = 100;
        return 0;
}
```

The program will not work because line 7 attempts to send the contents of the variable value to cout before the variable is defined. The compiler reads your program from top to bottom. If it encounters a statement that uses a variable before the variable is defined, an error will result. To correct the program, the variable definition must be put before any statement that uses it.

### 2.14 Arithmetic Operators

CONCEPT: There are many operators for manipulating numeric values and performing arithmetic operations.

C++ offers a multitude of operators for manipulating data. Generally, there are three types of operators: unary, binary, and ternary. These terms reflect the number of operands an operator requires.

VideoNote Assignment Statements and Simple Math Expressions

Unary operators only require a single operand. For example, consider the following expression:

```
-5
```

Of course, we understand this represents the value negative five. The literal 5 is preceded by the minus sign. The minus sign, when used this way, is called the negation operator. Since it only requires one operand, it is a unary operator.

Binary operators work with two operands. The assignment operator is in this category. Ternary operators, as you may have guessed, require three operands. C++ has only one ternary operator, which will be discussed in Chapter 4.
Arithmetic operations are very common in programming. Table 2-9 shows the common arithmetic operators in C++.

Table 2-9 Fundamental Arithmetic Operators

| Operator | Meaning | Type | Example |
| :---: | :--- | :--- | :--- |
| + | Addition | Binary | total $=$ cost + tax; |
| - | Subtraction | Binary | cost $=$ total - tax; |
| $*$ | Multiplication | Binary | tax $=$ cost * rate; |
| / | Division | Binary | salePrice $=$ original / 2; |
| $\%$ | Modulus | Binary | remainder $=$ value \% 3; |

Each of these operators works as you probably expect. The addition operator returns the sum of its two operands. In the following assignment statement, the variable amount will be assigned the value 12 :

```
amount = 4 + 8;
```

The subtraction operator returns the value of its right operand subtracted from its left operand. This statement will assign the value 90 to temperature:

```
temperature = 120 - 30;
```

The multiplication operator returns the product of its two operands. In the following statement, markUp is assigned the value 3:

```
markUp = 12 * 0.25;
```

The division operator returns the quotient of its left operand divided by its right operand. In the next statement, points is assigned the value 5:

```
points = 100 / 20;
```

It is important to note that when both of the division operator's operands are integers, the result of the division will also be an integer. If the result has a fractional part, it will be thrown away. We will discuss this behavior, which is known as integer division, in greater detail later in this section.

The modulus operator, which only works with integer operands, returns the remainder of an integer division. The following statement assigns 2 to leftOver:

```
1eftOver = 17 % 3;
```

In Chapter 3, you will learn how to use these operators in more complex mathematical formulas. For now, we will concentrate on their basic usage. For example, suppose we need to write a program that calculates and displays an employee's total wages for the week. The regular hours for the work week are 40, and any hours worked over 40 are considered overtime. The employee earns $\$ 18.25$ per hour for regular hours, and $\$ 27.78$ per hour for overtime hours. The employee has worked 50 hours this week. The following pseudocode algorithm shows the program's logic:

Regular wages $=$ base pay rate $\times$ regular hours
Overtime wages $=$ overtime pay rate $\times$ overtime hours
Total wages $=$ regular wages + overtime wages
Display the total wages
Program 2-21 shows the C++ code for the program.

## Program 2-21

```
// This program calculates hourly wages, including overtime.
#include <iostream>
using namespace std;
int main()
{
    double regularWages, // To hold regular wages
                basePayRate = 18.25, // Base pay rate
                regularHours = 40.0, // Hours worked less overtime
                overtimeWages, // To hold overtime wages
                overtimePayRate = 27.78, // Overtime pay rate
                overtimeHours = 10, // Overtime hours worked
                totalWages; // To hold total wages
    // Calculate the regular wages.
    regularWages = basePayRate * regularHours;
    // Calculate the overtime wages.
    overtimeWages = overtimePayRate * overtimeHours;
    // Calculate the total wages.
    totalWages = regularWages + overtimeWages;
    // Display the total wages.
    cout << "Wages for this week are $" << totalWages << endl;
    return 0;
}
```

## Program Output

Wages for this week are \$1007.8

Let's take a closer look at the program. As mentioned in the comments, there are variables for regular wages, base pay rate, regular hours worked, overtime wages, overtime pay rate, overtime hours worked, and total wages.

Here is line 16, which multiplies basePayRate by regularHours and stores the result in regularWages:

```
regularWages = basePayRate * regularHours;
```

Here is line 19, which multiplies overtimePayRate by overtimeHours and stores the result in overtimeWages:

```
overtimeWages = overtimePayRate * overtimeHours;
```

Line 22 adds the regular wages and the overtime wages and stores the result in totalWages:

```
totalWages = regularWages + overtimeWages;
```

Line 25 displays the message on the screen reporting the week's wages.

## Integer Division

When both operands of a division statement are integers, the statement will result in integer division. This means the result of the division will be an integer as well. If there is a remainder, it will be discarded. For example, look at the following code:

```
double number;
number = 5 / 2;
```

This code divides 5 by 2 and assigns the result to the number variable. What will be stored in number? You would probably assume that 2.5 would be stored in number because that is the result your calculator shows when you divide 5 by 2 . However, that is not what happens when the previous C++ code is executed. Because the numbers 5 and 2 are both integers, the fractional part of the result will be thrown away, or truncated. As a result, the value 2 will be assigned to the number variable.

In the previous code, it doesn't matter that the number variable is declared as a double because the fractional part of the result is discarded before the assignment takes place. In order for a division operation to return a floating-point value, one of the operands must be of a floating-point data type. For example, the previous code could be written as follows:

```
double number;
number = 5.0 / 2;
```

In this code, 5.0 is treated as a floating-point number, so the division operation will return a floating-point number. The result of the division is 2.5 .

## In the Spotlight:

## Calculating Percentages and Discounts

Determining percentages is a common calculation in computer programming. Although the $\%$ symbol is used in general mathematics to indicate a percentage, most programming languages (including $\mathrm{C}++$ ) do not use the $\%$ symbol for this purpose. In a program, you have to convert a percentage to a floating-point number, just as you would if you were using a calculator. For example, 50 percent would be written as 0.5 , and 2 percent would be written as 0.02 .

Let's look at an example. Suppose you earn $\$ 6,000$ per month and you are allowed to contribute a portion of your gross monthly pay to a retirement plan. You want to determine the amount of your pay that will go into the plan if you contribute 5 percent, 7 percent, or 10 percent of your gross wages. To make this determination, you write the program shown in Program 2-22.

## Program 2-22

// This program calculates the amount of pay that
// will be contributed to a retirement plan if $5 \%$,
// $7 \%$, or $10 \%$ of monthly pay is withheld.
\#include <iostream>

```
using namespace std;
int main()
{
    // Variables to hold the monthly pay and the
    // amount of contribution.
    double month1yPay = 6000.0, contribution;
    // Calculate and display a 5% contribution.
    contribution = monthlyPay * 0.05;
    cout << "5 percent is $" << contribution
        << " per month.\n";
    // Calculate and display a 7% contribution.
    contribution = month1yPay * 0.07;
    cout << "7 percent is $" << contribution
        << " per month.\n";
    // Calculate and display a 10% contribution.
    contribution = monthlyPay * 0.1;
    cout << "10 percent is $" << contribution
        << " per month.\n";
    return 0;
}
```

## Program Output

5 percent is $\$ 300$ per month.
7 percent is $\$ 420$ per month.
10 percent is $\$ 600$ per month.

Line 11 defines two variables: month1yPay and contribution. The month1yPay variable, which is initialized with the value 6000 .0, holds the amount of your monthly pay. The contribution variable will hold the amount of a contribution to the retirement plan.
The statements in lines 14 through 16 calculate and display 5 percent of the monthly pay. The calculation is done in line 14 , where the monthlyPay variable is multiplied by 0.05 . The result is assigned to the contribution variable, which is then displayed in line 15.

Similar steps are taken in lines 18 through 21, which calculate and display 7 percent of the monthly pay, and lines 24 through 26 , which calculate and display 10 percent of the monthly pay.

## Calculating a Percentage Discount

Another common calculation is determining a percentage discount. For example, suppose a retail business sells an item that is regularly priced at $\$ 59.95$, and is planning to have a sale where the item's price will be reduced by 20 percent. You have been asked to write a program to calculate the sale price of the item.

To determine the sale price, you perform two calculations:

- First, you get the amount of the discount, which is 20 percent of the item's regular price.
- Second, you subtract the discount amount from the item's regular price. This gives you the sale price.

Program 2-23 shows how this is done in $\mathrm{C}++$.

## Program 2-23

```
// This program calculates the sale price of an item
// that is regularly priced at $59.95, with a 20 percent
// discount subtracted.
#include <iostream>
using namespace std;
int main()
{
    // Variables to hold the regular price, the
    // amount of a discount, and the sale price.
    double regularPrice = 59.95, discount, salePrice;
    // Calculate the amount of a 20% discount.
    discount = regularPrice * 0.2;
    // Calculate the sale price by subtracting the
    // discount from the regular price.
    salePrice = regularPrice - discount;
    // Display the results.
    cout << "Regular price: $" << regularPrice << endl;
    cout << "Discount amount: $" << discount << endl;
    cout << "Sale price: $" << salePrice << endl;
    return 0;
}
```

## Program Output

Regular price: \$59.95
Discount amount: \$11.99
Sale price: $\$ 47.96$

Line 11 defines three variables. The regularPrice variable holds the item's regular price, and is initialized with the value 59.95 . The discount variable will hold the amount of the discount once it is calculated. The salePrice variable will hold the item's sale price.

Line 14 calculates the amount of the 20 percent discount by multiplying regularPrice by 0.2 . The result is stored in the discount variable. Line 18 calculates the sale price by subtracting discount from regularPrice. The result is stored in the salePrice variable. The cout statements in lines 21 through 23 display the item's regular price, the amount of the discount, and the sale price.

## In the Spotlight:

## Using the Modulus Operator and Integer Division

The modulus operator (\%) is surprisingly useful. For example, suppose you need to extract the rightmost digit of a number. If you divide the number by 10 , the remainder will be the rightmost digit. For instance, $123 \div 10=12$ with a remainder of 3 . In a computer program, you would use the modulus operator to perform this operation. Recall that the modulus operator divides an integer by another integer, and gives the remainder. This is demonstrated in Program 2-24. The program extracts the rightmost digit of the number 12345.

## Program 2-24

```
// This program extracts the rightmost digit of a number.
#include <iostream>
using namespace std;
int main()
{
    int number = 12345;
    int rightMost = number % 10;
    cout << "The rightmost digit in "
            << number << " is "
            << rightMost << endl;
        return 0;
}
```

## Program Output

```
The rightmost digit in 12345 is 5
```

Interestingly, the expression number \% 100 will give you the rightmost two digits in number, the expression number \% 1000 will give you the rightmost three digits in number, and so on.

The modulus operator (\%) is useful in many other situations. For example, Program 2-25 converts 125 seconds to an equivalent number of minutes, and seconds.

## Program 2-25

```
// This program converts seconds to minutes and seconds.
#include <iostream>
using namespace std;
int main()
{
    // The total seconds is 125.
```

## Program 2-25 (continued)

```
    int totalSeconds = 125;
    // Variables for the minutes and seconds
    int minutes, seconds;
    // Get the number of minutes.
minutes = tota1Seconds / 60;
    // Get the remaining seconds.
    seconds = totalSeconds % 60;
    // Display the results.
    cout << totalSeconds << " seconds is equivalent to:\n";
    cout << "Minutes: " << minutes << endl;
    cout << "Seconds: " << seconds << endl;
    return 0;
}
```

## Program Output

125 seconds is equivalent to:
Minutes: 2
Seconds: 5

Let's take a closer look at the code:

- Line 8 defines an int variable named totalSeconds, initialized with the value 125.
- Line 11 declares the int variables minutes and seconds.
- Line 14 calculates the number of minutes in the specified number of seconds. There are 60 seconds in a minute, so this statement divides tota1Seconds by 60 . Notice we are performing integer division in this statement. Both totalSeconds and the numeric literal 60 are integers, so the division operator will return an integer result. This is intentional because we want the number of minutes with no fractional part.
- Line 17 calculates the number of remaining seconds. There are 60 seconds in a minute, so this statement uses the \% operator to divide the totalSeconds by 60 , and get the remainder of the division. The result is the number of remaining seconds.
- Lines 20 through 22 display the number of minutes and seconds.

## Checkpoint

2.21 Is the following assignment statement valid or invalid? If it is invalid, why?

```
72 = amount;
```

2.22 How would you consolidate the following definitions into one statement?

```
int x = 7;
int y = 16;
int z = 28;
```

2.23 What is wrong with the following program? How would you correct it?

```
#include <iostream>
using namespace std;
int main()
{
    number = 62.7;
    double number;
    cout << number << endl;
    return 0;
}
```

2.24 Is the following an example of integer division or floating-point division? What value will be stored in portion?

```
portion = 70 / 3;
```

### 2.15 Comments

CONCEPT: Comments are notes of explanation that document lines or sections of a program. Comments are part of the program, but the compiler ignores them. They are intended for people who may be reading the source code.

It may surprise you that one of the most important parts of a program has absolutely no impact on the way it runs. In fact, the compiler ignores this part of a program. Of course, I'm speaking of the comments.

As a beginning programmer, you might be resistant to the idea of liberally writing comments in your programs. After all, it can seem more productive to write code that actually does something! It is crucial, however, that you develop the habit of thoroughly annotating your code with descriptive comments. It might take extra time now, but it will almost certainly save time in the future.
Imagine writing a program of medium complexity with about 8,000 to 10,000 lines of C++ code. Once you have written the code and satisfactorily debugged it, you happily put it away and move on to the next project. Ten months later, you are asked to make a modification to the program (or worse, track down and fix an elusive bug). You open the file that contains your source code and stare at thousands of statements that now make no sense at all. If only you had left some notes to yourself explaining the program's code. Of course it's too late now. All that's left to do is decide what will take less time: figuring out the old program, or completely rewriting it!
This scenario might sound extreme, but it's one you don't want to happen to you. Realworld programs are big and complex. Thoroughly documented code will make your life easier, not to mention the other programmers who may have to read your code in the future.

## Single-Line Comments

You have already seen one way to place comments in a C++ program. You simply place two forward slashes (//) where you want the comment to begin. The compiler ignores
everything from that point to the end of the line. Program 2-26 shows that comments may be placed liberally throughout a program.

## Program 2-26

```
// PROGRAM: PAYROLL.CPP
// Written by Herbert Dorfmann
// This program calculates company payroll
// Last modification: 8/20/2017
#include <iostream>
using namespace std;
int main()
{
        double payRate; // Holds the hourly pay rate
        double hours; // Holds the hours worked
    int employNumber; // Holds the employee number
(The remainder of this program is left out.)
```

In addition to telling who wrote the program and describing the purpose of variables, comments can also be used to explain complex procedures in your code.

## Multi-Line Comments

The second type of comment in C++ is the multi-line comment. Multi-line comments start with /* (a forward slash followed by an asterisk) and end with */ (an asterisk followed by a forward slash). Everything between these markers is ignored. Program 2-27 illustrates how multi-line comments may be used. Notice a multi-line comment starts in line 1 with the $/ *$ symbol, and it ends in line 6 with the */ symbol.

## Program 2-27

```
/*
            PROGRAM: PAYROLL.CPP
            Written by Herbert Dorfmann
            This program calculates company payroll
            Last modification: 8/20/2017
*/
#include <iostream>
using namespace std;
int main()
{
    double payRate; // Holds the hourly pay rate
    double hours; // Holds the hours worked
    int employNumber; // Holds the employee number
```

(The remainder of this program is left out.)

Unlike a comment started with / /, a multi-line comment can span several lines. This makes it more convenient to write large blocks of comments because you do not have to mark every line. Consequently, the multi-line comment is inconvenient for writing single-line comments because you must type both a beginning and ending comment symbol.

NOTE: Many programmers use a combination of single-line comments and multi-line comments in their programs. Convenience usually dictates which style to use.

Remember the following advice when using multi-line comments:

- Be careful not to reverse the beginning symbol with the ending symbol.
- Be sure not to forget the ending symbol.

Both of these mistakes can be difficult to track down and will prevent the program from compiling correctly.

### 2.16 Named Constants

## CONCEPT: Literals may be given names that symbolically represent them in

 a program.Assume the following statement appears in a banking program that calculates data pertaining to loans:

```
amount = balance * 0.069;
```

In such a program, two potential problems arise. First, it is not clear to anyone other than the original programmer what 0.069 is. It appears to be an interest rate, but in some situations there are fees associated with loan payments. How can the purpose of this statement be determined without painstakingly checking the rest of the program?
The second problem occurs if this number is used in other calculations throughout the program and must be changed periodically. Assuming the number is an interest rate, what if the rate changes from 6.9 percent to 7.2 percent? The programmer will have to search through the source code for every occurrence of the number.
Both of these problems can be addressed by using named constants. A named constant is like a variable, but its content is read-only and cannot be changed while the program is running. Here is a definition of a named constant:

```
const double INTEREST_RATE = 0.069;
```

It looks just like a regular variable definition except that the word const appears before the data type name, and the name of the variable is written in all uppercase characters. The key word const is a qualifier that tells the compiler to make the variable read-only. Its value will remain constant throughout the program's execution. It is not required that the variable name be written in all uppercase characters, but many programmers prefer to write them this way so that they are easily distinguishable from regular variable names.
An initialization value must be given when defining a constant with the const qualifier, or an error will result when the program is compiled. A compiler error will also result if there are any statements in the program that attempt to change the value of a named constant.

An advantage of using named constants is that they make programs more self-documenting. The statement

```
amount = balance * 0.069;
```

can be changed to read

```
amount = balance * INTEREST_RATE;
```

A new programmer can read the second statement and know what is happening. It is evident that balance is being multiplied by the interest rate. Another advantage to this approach is that widespread changes can easily be made to the program. Let's say the interest rate appears in a dozen different statements throughout the program. When the rate changes, the initialization value in the definition of the named constant is the only value that needs to be modified. If the rate increases to 7.2 percent, the definition is changed to the following:

```
const double INTEREST_RATE = 0.072;
```

The program is then ready to be recompiled. Every statement that uses INTEREST_RATE will then use the new value.

Named constants can also help prevent typographical errors in a program's code. For example, suppose you use the number 3.14159 as the value of $p i$ in a program that performs various geometric calculations. Each time you type the number 3.14159 in the program's code, there is a chance that you will make a mistake with one or more of the digits. As a result, the program will not produce the correct results. To help prevent a mistake such as this, you can define a named constant for $p i$, initialized with the correct value, then use that constant in all of the formulas that require its value. Program 2-28 shows an example. It calculates the circumference of a circle that has a diameter of 10.

## Program 2-28

```
// This program calculates the circumference of a circle.
#include <iostream>
using namespace std;
int main()
{
    // Constants
    const double PI = 3.14159;
    const double DIAMETER = 10.0;
    // Variable to hold the circumference
    double circumference;
    // Calculate the circumference.
    circumference = PI * DIAMETER;
    // Display the circumference.
    cout << "The circumference is: " << circumference << endl;
    return 0;
}
```

## Program Output

The circumference is: 31.4159

Let's take a closer look at the program. Line 8 defines a constant double named PI, initialized with the value 3.14159 . This constant will be used for the value of $p i$ in the program's calculation. Line 9 defines a constant double named DIAMETER, initialized with the value 10. This will be used for the circle's diameter. Line 12 defines a double variable named circumference, which will be used to hold the circle's circumference. Line 15 calculates the circle's circumference by multiplying PI by DIAMETER. The result of the calculation is assigned to the circumference variable. Line 18 displays the circle's circumference.

## Checkpoint

2.25 Write statements using the const qualifier to create named constants for the following literal values:
Literal Value Description
2.71828 Euler's number (known in mathematics as $e$ )
5.256E5 Number of minutes in a year
32.2 The gravitational acceleration constant (in ft/s ${ }^{2}$ )
9.8 The gravitational acceleration constant (in m/s ${ }^{2}$ )

1609 Number of meters in a mile

### 2.17 Programming Style

CONCEPT: Programming style refers to the way a programmer uses identifiers, spaces, tabs, blank lines, and punctuation characters to visually arrange a program's source code. These are some, but not all, of the elements of programming style.

In Chapter 1, you learned that syntax rules govern the way a language may be used. The syntax rules of C++ dictate how and where to place key words, semicolons, commas, braces, and other components of the language. The compiler's job is to check for syntax errors and, if there are none, generate object code.

When the compiler reads a program, it processes it as one long stream of characters. The compiler doesn't care that each statement is on a separate line, or that spaces separate operators from operands. Humans, on the other hand, find it difficult to read programs that aren't written in a visually pleasing manner. Consider Program 2-29 for example.

## Program 2-29

1 \#include <iostream>
2 using namespace std;int main()\{double shares=220.0;
3 double avgPrice=14.67; cout<<"There were "<<shares
4 <<" shares sold at \$"<<avgPrice<<" per share. In";
5 return 0;\}

## Program Output

There were 220 shares sold at $\$ 14.67$ per share.

Although the program is syntactically correct (it doesn't violate any rules of C++), it is very difficult to read. The same program is shown in Program 2-30, written in a more reasonable style.

## Program 2-30

```
// This example is much more readable than Program 2-29.
#include <iostream>
using namespace std;
int main()
{
    double shares = 220.0;
    double avgPrice = 14.67;
    cout << "There were " << shares << " shares sold at $";
    cout << avgPrice << " per share.\n";
    return 0;
}
```

## Program Output

There were 220 shares sold at $\$ 14.67$ per share.
Programming style refers to the way source code is visually arranged. Ideally, it is a consistent method of putting spaces and indentions in a program so visual cues are created. These cues quickly tell a programmer important information about a program.
For example, notice in Program 2-30 that inside the function main's braces each line is indented. It is a common C++ style to indent all the lines inside a set of braces. You will also notice the blank line between the variable definitions and the cout statements. This is intended to visually separate the definitions from the executable statements.

NOTE: Although you are free to develop your own style, you should adhere to common programming practices. By doing so, you will write programs that visually make sense to other programmers.

Another aspect of programming style is how to handle statements that are too long to fit on one line. Because C++ is a free-flowing language, it is usually possible to spread a statement over several lines. For example, here is a cout statement that uses five lines:

```
cout << "The Fahrenheit temperature is "
    << fahrenheit
    << " and the Celsius temperature is "
    << celsius
    << endl;
```

This statement will work just as if it were typed on one line. Here is an example of variable definitions treated similarly:

```
int fahrenheit,
    celsius,
    kelvin;
```

There are many other issues related to programming style. They will be presented throughout the book.

## Review Questions and Exercises

## Short Answer

1. How many operands does each of the following types of operators require?
$\qquad$ Unary
$\qquad$ Binary
___ Ternary
2. How may the double variables temp, weight, and age be defined in one statement?
3. How can the values of three variables length, breadth, and height be displayed using one statement, such that each variable is displayed in a new line?
4. Assume that $x$ is an integer variable, $y$ is a floating-point variable, and $z$ is a character variable. Write statements in C++ to perform the following operations:
A) Add 10 to $x$.
B) Square the value of $y$.
C) Divide x by 7 and store the result in y .
D) Store ' \& ' in $z$.
E) Display the values of $y$ and $z$ on the screen.
F) Display the rightmost digit of $x$ on the screen.
G) Display the number of bytes used by an integer variable.
5. Is the following comment written using single-line or multi-line comment symbols?
```
/* This program was written by M. A. Codewriter*/
```

6. Is the following comment written using single-line or multi-line comment symbols?
```
// This program was written by M. A. Codewriter
```

7. Modify the following program so it prints two blank lines between each line of text.
```
#include <iostream>
using namespace std;
int main()
{
    cout << "Two mandolins like creatures in the";
    cout << "dark";
    cout << "Creating the agony of ecstasy.";
    cout << " - George Barker";
    return 0;
}
```

8. What will the following programs print on the screen?
```
A) #include <iostream>
    using namespace std;
    int main()
    {
        int freeze = 32, boil = 212;
```

```
        freeze = 0;
        boil = 100;
        cout << freeze << endl << boil << endl;
        return 0;
    }
B) #include <iostream>
    using namespace std;
    int main()
    {
        int x = 0, y = 2;
        x = y * 4;
        cout << x << endl << y << endl;
        return 0;
    }
C) #include <iostream>
    using namespace std;
    int main()
    {
        cout << "I am the incredible";
        cout << "computing\nmachine";
        cout << "\nand I will\namaze\n";
        cout << "you.";
        return 0;
    }
D) #include <iostream>
    using namespace std;
    int main()
    {
        cout << "Be careful\n";
        cout << "This might/n be a trick ";
        cout << "question\n";
        return 0;
    }
E) #include <iostream>
    using namespace std;
    int main()
    {
        int a, x = 23;
        a = x % 2;
        cout << x << endl << a << endl;
        return 0;
    }
```

## Multiple Choice

9. Which of the following statements is correct?
A) cout $\ll x$.
B) cout $\gg x$;
C) cout $\ll x$;
D) cout $\gg x$.
10. Which of the following statements is correct?
A) \#include (iostream)
B) \#include \{iostream\}
C) \#include <iostream>
D) \#include [iostream]
E) All of the above
11. When you are writing cout, you are using
A) a ternary operator
B) a library function
C) a stream insertion operator
D) a stream object
12. Preprocessor directives begin with $\qquad$ .
A) \#
B) !
C) <
D) *
E) None of the above
13. The following data

72
'A'
"Hello World"
2.8712
are all examples of $\qquad$ .
A) variables
B) literals or constants
C) strings
D) none of the above
14. If ch is a char type of variable, which of the following statements is wrong?
A) ch="abcd";
B) $c h=' a ' ;$
C) $c h=' 6 '$;
D) ch='?';
15. Which of the following is wrong with respect to an arithmetic statement?
A) The 1 value is assigned to the rvalue.
B) It always has a binary operator in it.
C) It usually evaluates to a numeric value.
D) It occurs within a function.
16. Which of the following are not valid cout statements? (Select all that apply.)
A) cout << "Hello World";
B) cout << "Have a nice day" $\$ n;
C) cout < value;
D) cout << Programming is great fun;
17. Assume $w=5, x=4, y=8$, and $z=2$. What value will be stored in result in each of the following statements?
A) result $=x+y$;
B) result $=z$ * 2 ;
C) result $=y / x$;
D) result $=y-z$;
E) result $=w \% 2$;
18. How would each of the following numbers be represented in E notation?
A) $3.287 \times 10^{6}$
B) $-978.65 \times 10^{12}$
C) $7.65491 \times 10^{-3}$
D) $-58710.23 \times 10^{-4}$
19. The negation operator is $\qquad$ .
A) unary
B) binary
C) ternary
D) none of the above
20. A(n) $\qquad$ is like a variable, but its value is read-only and cannot be changed during the program's execution.
A) secure variable
B) uninitialized variable
C) named constant
D) locked variable
21. When do preprocessor directives execute?
A) Before the compiler compiles your program
B) After the compiler compiles your program
C) At the same time as the compiler compiles your program
D) None of the above

## True or False

22. T F A variable must be defined before it can be used.
23. T F The cout object is used along with the stream insertion operator.
24. T F Variable names may be up to 31 characters long.
25. T F A left brace in a C++ program should always be followed by a right brace later in the program.
26. T F The variable name Qwert@\#1 is legal.

## Algorithm Workbench

27. Convert the following pseudocode to $\mathrm{C}++$ code. Be sure to define the appropriate variables.

Store 20 in the speed variable.
Store 10 in the time variable.
Multiply speed by time and store the result in the distance variable. Display the contents of the distance variable.
28. Convert the following pseudocode to $\mathrm{C}++$ code. Be sure to define the appropriate variables. Store 10.5 in the radius variable.
Store 20 in the height variable.
Multiply 3.141593, the square of radius, and the height and store the result in the volume variable.
Display the contents of the volume variable.

## Find the Error

29. There are a number of syntax errors in the following program. Locate as many as you can.
```
*/ What's wrong with this program? /*
#include iostream
using namespace std;
int main();
}
    int a, b, c \\ Three integers
    a = 3
    b = 4
    c = a + b
    Cout < "The value of c is %d" < C;
    return 0;
{
```

## Programming Challenges

Visit www.myprogramminglab.com to complete many of these Programming Challenges online and get instant feedback.

## 1. Product of Three Numbers

Write a program that assigns the values 10,20 , and 30 to three integer variables and then stores the product of these three variables in another variable, product.

## 2. The Golden Ratio

The golden ratio is a ratio that appears in nature and produces pleasing, harmonious proportions. For rectangles, if the width is approximately 1.62 times the height, they will be in this ratio. Write a program that calculates the appropriate width for a rectangle with height 5 cm so that it fulfills this ratio.

## 3. Display Count of Lines

Write a program that displays the count of lines with and without comments for a program of 1050 lines in total. Assume that 36 percent of the lines contain comments.

## 4. Restaurant Bill

Write a program that computes the tax and tip on a restaurant bill for a patron with a $\$ 88.67$ meal charge. The tax should be 6.75 percent of the meal cost. The tip should
be 20 percent of the total after adding the tax. Display the meal cost, tax amount, tip amount, and total bill on the screen.

## 5. Pounds to Kilograms

The SI system of units is an internationally agreed decimal system of measurement that uses the kilogram as the unit of weight. Earlier systems used different units, such as the stone. In 1835, the United Kingdom defined the stone as weighing 14 pounds, or 6.35 kg . Write a program that stores your personal weight in pounds in a variable and calculates and displays your weight in both stones and kilograms.

TIP: Use the double data type for all variables in this program.

## 6. Total Calories

In most countries, it is compulsory to display the total calories on the label of prepackaged food. For strawberry jam this is very easy, because there are only three ingredients: strawberries, sugar, and lemon juice, and for every 100 g strawberries, there is 100 g of sugar and 5 g of lemon juice.
Write a program that defines the following variables:
strawberriesKca1 This variable will hold the number of kilocalories per 100 g of strawberries. Initialize the variable to 36.
sugarKca1
This variable will hold the number of kilocalories per 100 g of sugar. Initialize the variable to 40 .
1 emonKca1 This variable will hold the number of kilocalories per 100 g of lemon juice. Initialize the variable to 32.

The program should calculate the total amount of jam produced by starting out with 400 g of strawberries. It should also calculate the total kilocalories present in this amount of jam. Display the total amount of jam and the total kilocalories on the screen.

## 7. Ocean Levels

Assuming the ocean's level is currently rising at about 1.5 millimeters per year, write a program that displays:

- The number of millimeters higher than the current level that the ocean's level will be in 5 years.
- The number of millimeters higher than the current level that the ocean's level will be in 7 years.
- The number of millimeters higher than the current level that the ocean's level will be in 10 years.

## 8. Total Purchase

A customer in a store is purchasing five items. The prices of the five items are as follows:
Price of item $1=\$ 15.95$
Price of item $2=\$ 24.95$
Price of item $3=\$ 6.95$
Price of item $4=\$ 12.95$
Price of item $5=\$ 3.95$

Write a program that holds the prices of the five items in five variables. Display each item's price, the subtotal of the sale, the amount of sales tax, and the total. Assume the sales tax is 7 percent.

## 9. Cyborg Data Type Sizes

You have been given a job as a programmer on a Cyborg supercomputer. In order to accomplish some calculations, you need to know how many bytes the following data types use: char, int, float, and double. You do not have any technical documentation, so you can't look this information up. Write a C++ program that will determine the amount of memory used by these types and display the information on the screen.

## 10. Digital Colors

Digital colors can be represented as a combination of red, green, and blue, with an alpha value specifying how opaque they are. Each value is one byte, and thus in the range of 0 to 255 . Instead of having 4 one-byte values, the colors can be stored in one unsigned int of 4 bytes. The single number is a sum of the alpha value multiplied by $16,777,216$; the red multiplied with 65,536 ; the green with 256 ; and blue. Write a program that represents the color $(128,255,128,64)$, where the first value is the alpha value.

## 11. Distance per Tank of Gas

A car with a 20-gallon gas tank averages 23.5 miles per gallon when driven in town, and 28.9 miles per gallon when driven on the highway. Write a program that calculates and displays the distance the car can travel on one tank of gas when driven in town and when driven on the highway.
Hint: The following formula can be used to calculate the distance:
Distance $=$ Number of Gallons $\times$ Average Miles per Gallon

## 12. Weight of Freight

One ton is equivalent to 2240 pounds. Write a program that calculates the weight, in tons, of freight that weighs 10,158 pounds.

## 13. Surface Area and Volume of a Sphere

The surface area of a sphere of radius $r$ is calculated by using the formula $A=4 \pi r^{2}$, and its volume is calculated by using the formula $\mathrm{V}=(4 / 3) \pi r^{3}$. Write a program that calculates the surface area and volume of a sphere that has a radius of 8 cm . (Note: $\pi=3.1415926535$ )

## 14. Rainfall Information

Rain is collected in a pluviometer to determine how much rain has fallen during a certain period of time. Suppose that a pluviometer contained 3 liters at 0:00 and 15 liters at 6:00. Write a program that displays the following pieces of information, each on a separate line:
The total rain during the observed period
The average per hour
The expected amount for the entire day of 24 hours if the rain continues with the same intensity
Use a single cout statement to display all information.

## 15. Triangle Pattern

Write a program that displays the following pattern on the screen:
16. Diamond Pattern

Write a program that displays the following pattern:
*
***
*****
*******
\#***
***
*

## 17. Stock Commission

Kathryn bought 750 shares of stock at a price of $\$ 35.00$ per share. She must pay her stockbroker a 2 percent commission for the transaction. Write a program that calculates and displays the following:

- The amount paid for the stock alone (without the commission).
- The amount of the commission.
- The total amount paid (for the stock plus the commission).

## 18. Energy Drink Consumption

A soft drink company recently surveyed 16,500 of its customers and found that approximately 15 percent of those surveyed purchase one or more energy drinks per week. Of those customers who purchase energy drinks, approximately 58 percent of them prefer citrus-flavored energy drinks. Write a program that displays the following:

- The approximate number of customers in the survey who purchase one or more energy drinks per week.
- The approximate number of customers in the survey who prefer citrus-flavored energy drinks.

## 19. Annual High Temperatures

The average July high temperature is 85 degrees Fahrenheit in New York City, 88 degrees Fahrenheit in Denver, and 106 degrees Fahrenheit in Phoenix. Write a program that calculates and reports what the new average July high temperature would be for each of these cities if temperatures rise by 2 percent.

## 20. How Much Paint

A particular brand of paint covers 340 square feet per gallon. Write a program to determine and report approximately how many gallons of paint will be needed to paint two coats on a wooden fence that is 6 feet high and 100 feet long.

## 3．1 The cin Object

CONCEPT：The cin object can be used to read data typed at the keyboard．
So far you have written programs with built－in data．Without giving the user an opportu－ nity to enter his or her own data，you have initialized the variables with the necessary start－ ing values．These types of programs are limited to performing their task with only a single
must be modified and recompiled．

In reality，most programs ask for values that will be assigned to variables．This means the program does not have to be modified if the user wants to run it several times with different sets of data．For example，a program that calculates payroll for a small busi－ ness might ask the user to enter the name of the employee，the hours worked，and the hourly pay rate．When the paycheck for that employee has been printed，the program could start over again and ask for the name，hours worked，and hourly pay rate of the next employee．
Just as cout is C＋＋＇s standard output object，cin is the standard input object．It reads input from the console（or keyboard）as shown in Program 3－1．

## Program 3-1

```
// This program asks the user to enter the length and width of
// a rectangle. It calculates the rectangle's area and displays
// the value on the screen.
#include <iostream>
using namespace std;
int main()
{
    int length, width, area;
    cout << "This program calculates the area of a ";
    cout << "rectangle.\n";
    cout << "What is the length of the rectangle? ";
    cin >> length;
    cout << "What is the width of the rectangle? ";
    cin >> width;
    area = length * width;
    cout << "The area of the rectangle is " << area << ".\n";
    return 0;
}
```

## Program Output with Example Input Shown in Bold

This program calculates the area of a rectangle.
What is the length of the rectangle? 10 Enter
What is the width of the rectangle? 20 Enter
The area of the rectangle is 200.

Instead of calculating the area of one rectangle, this program can be used to get the area of any rectangle. The values that are stored in the length and width variables are entered by the user when the program is running. Look at lines 13 and 14:

```
cout << "What is the length of the rectangle? ";
cin >> length;
```

In line 13 , the cout object is used to display the question "What is the length of the rectangle?" This question is known as a prompt, and it tells the user what data he or she should enter. Your program should always display a prompt before it uses cin to read input. This way, the user will know that he or she must type a value at the keyboard.

Line 14 uses the cin object to read a value from the keyboard. The >> symbol is the stream extraction operator. It gets characters from the stream object on its left and stores them in the variable whose name appears on its right. In this line, characters are taken from the cin object (which gets them from the keyboard) and are stored in the length variable.

Gathering input from the user is normally a two-step process:

1. Use the cout object to display a prompt on the screen.
2. Use the cin object to read a value from the keyboard.

The prompt should ask the user a question, or tell the user to enter a specific value. For example, the code we just examined from Program 3-1 displays the following prompt:

```
What is the length of the rectangle?
```

When the user sees this prompt, he or she knows to enter the rectangle's length. After the prompt is displayed, the program uses the cin object to read a value from the keyboard and store the value in the length variable.

Notice the << and >> operators appear to point in the direction that data is flowing. In a statement that uses the cout object, the $\ll$ operator always points toward cout. This indicates that data is flowing from a variable or a literal to the cout object. In a statement that uses the cin object, the >> operator always points toward the variable that is receiving the value. This indicates that data is flowing from cin to a variable. This is illustrated in Figure 3-1.

Figure 3-1 The << and >> operators

```
cout << "What is the length of the rectangle? ";
cin >> length;
```

Think of the << and >> operators as arrows that point in the direction that data is flowing.

```
cout \leftarrow "What is the length of the rectangle? ";
```

cin $\rightarrow$ 1ength;

The cin object causes a program to wait until data is typed at the keyboard and the Enter key is pressed. No other lines in the program will be executed until cin gets its input.
cin automatically converts the data read from the keyboard to the data type of the variable used to store it. If the user types 10 , it is read as the characters ' 1 ' and ' 0 '. cin is smart enough to know this will have to be converted to an int value before it is stored in the length variable. cin is also smart enough to know a value like 10.7 cannot be stored in an integer variable. If the user enters a floating-point value for an integer variable, cin will not read the part of the number after the decimal point.

NOTE: You must include the <iostream> header file in any program that uses cin.

## Entering Multiple Values

The cin object may be used to gather multiple values at once. Look at Program 3-2, which is a modified version of Program 3-1.
Line 15 waits for the user to enter two values. The first is assigned to length and the second to width.

```
cin >> length >> width;
```

## Program 3-2

```
// This program asks the user to enter the length and width of
// a rectangle. It calculates the rectangle's area and displays
// the value on the screen.
#include <iostream>
using namespace std;
int main()
{
        int length, width, area;
        cout << "This program calculates the area of a ";
        cout << "rectangle.\n";
        cout << "Enter the length and width of the rectangle ";
        cout << "separated by a space.\n";
        cin >> length >> width;
        area = length * width;
        cout << "The area of the rectangle is " << area << endl;
        return 0;
}
```

## Program Output with Example Input Shown in Bold

This program calculates the area of a rectangle.
Enter the length and width of the rectangle separated by a space.
1020 Enter
The area of the rectangle is 200

In the example output, the user entered 10 and 20 , so 10 is stored in length and 20 is stored in width.

Notice the user separates the numbers by spaces as they are entered. This is how cin knows where each number begins and ends. It doesn't matter how many spaces are entered between the individual numbers. For example, the user could have entered

```
1 0
20
```

NOTE: The Enter key is pressed after the last number is entered.
cin will also read multiple values of different data types. This is shown in Program 3-3.

## Program 3-3

// This program demonstrates how cin can read multiple values
// of different data types.
\#include <iostream> using namespace std;
5

```
int main()
{
    int whole;
    double fractional;
    char letter;
    cout << "Enter an integer, a double, and a character: ";
    cin >> whole >> fractional >> letter;
    cout << "Whole: " << whole << endl;
    cout << "Fractiona1: " << fractional << endl;
    cout << "Letter: " << letter << endl;
    return 0;
}
```

## Program Output with Example Input Shown in Bold

```
Enter an integer, a double, and a character: 4 5.7 b Enter
Whole: 4
Fractional: 5.7
Letter: b
```

As you can see in the example output, the values are stored in their respective variables. But what if the user had responded in the following way?

```
Enter an integer, a double, and a character: 5.74b Enter
```

When the user types values at the keyboard, those values are first stored in an area of memory known as the keyboard buffer. So, when the user enters the values 5.7, 4, and b, they are stored in the keyboard buffer as shown in Figure 3-2.

Figure 3-2 The keyboard buffer
Keyboard buffer

When the user presses the Enter key, cin reads the value 5 into the variable whole. It does not read the decimal point because whole is an integer variable. Next it reads .7 and stores that value in the double variable fractional. The space is skipped, and 4 is the next value read. It is stored as a character in the variable letter. Because this cin statement reads only three values, the $b$ is left in the keyboard buffer. So, in this situation the program would have stored 5 in whole, 0.7 in fractional, and the character ' 4 ' in letter. It is important that the user enters values in the correct order.

## Checkpoint

3.1 What header file must be included in programs using cin?
3.2 True or false: cin requires the user to press the Enter key when finished entering data.
3.3 Assume value is an integer variable. If the user enters 3.14 in response to the following programming statement, what will be stored in value?
cin >> value;
A) 3.14
B) 3
C) 0
D) Nothing. An error message is displayed.
3.4 A program has the following variable definitions.
long miles;
int feet;
float inches;
Write one cin statement that reads a value into each of these variables.
3.5 The following program will run, but the user will have difficulty understanding what to do. How would you improve the program?

```
// This program multiplies two numbers and displays the result.
#include <iostream>
using namespace std;
int main()
{
    double first, second, product;
    cin >> first >> second;
    product = first * second;
    cout << product;
    return 0;
}
```

3.6 Complete the following program skeleton so it asks for the user's weight (in pounds) and displays the equivalent weight in kilograms.

```
#include <iostream>
using namespace std;
int main()
{
    double pounds, kilograms;
    // Write code here that prompts the user
    // to enter his or her weight and reads
    // the input into the pounds variable.
    // The following line does the conversion.
    kilograms = pounds / 2.2;
    // Write code here that displays the user's weight
    // in kilograms.
    return 0;
}
```

### 3.2 Mathematical Expressions

CONCEPT: C++ allows you to construct complex mathematical expressions using multiple operators and grouping symbols.

In Chapter 2, you were introduced to the basic mathematical operators, which are used to build mathematical expressions. An expression is a programming statement that has a value. Usually, an expression consists of an operator and its operands. Look at the following statement:

```
sum = 21 + 3;
```

Since $21+3$ has a value, it is an expression. Its value, 24 , is stored in the variable sum. Expressions do not have to be in the form of mathematical operations. In the following statement, 3 is an expression.

```
number = 3;
```

Here are some programming statements where the variable result is being assigned the value of an expression:

```
result = x;
result = 4;
result = 15 / 3;
result = 22 * number;
result = sizeof(int);
result = a + b + c;
```

In each of these statements, a number, variable name, or mathematical expression appears on the right side of the $=$ symbol. A value is obtained from each of these and stored in the variable result. These are all examples of a variable being assigned the value of an expression.
Program 3-4 shows how mathematical expressions can be used with the cout object.

## Program 3-4

```
// This program asks the user to enter the numerator
// and denominator of a fraction and it displays the
// decimal value.
#include <iostream>
using namespace std;
int main()
{
        double numerator, denominator;
        cout << "This program shows the decimal value of ";
        cout << "a fraction.\n";
```

```
Program 3-4
    (continued)
14 cout << "Enter the numerator: ";
15 cin >> numerator;
16 cout << "Enter the denominator: ";
17 cin >> denominator;
18 cout << "The decimal value is ";
19 cout << (numerator / denominator) << endl;
20 return 0;
21 }
```

## Program Output with Example Input Shown in Bold

```
This program shows the decimal value of a fraction.
Enter the numerator: 3 Enter
Enter the denominator: 16 Enter
The decimal value is 0.1875
```

The cout object will display the value of any legal expression in C++. In Program 3-4, the value of the expression numerator / denominator is displayed.

NOTE: The example input for Program $3-4$ shows the user entering 3 and 16 . Since these values are assigned to double variables, they are stored as the double values 3.0 and 16.0.

NOTE: When sending an expression that consists of an operator to cout, it is always a good idea to put parentheses around the expression. Some advanced operators will yield unexpected results otherwise.

## Operator Precedence

It is possible to build mathematical expressions with several operators. The following statement assigns the sum of $17, x, 21$, and $y$ to the variable answer.

```
answer = 17 + x + 21 + y;
```

Some expressions are not that straightforward, however. Consider the following statement:

```
outcome = 12 + 6 / 3;
```

What value will be stored in outcome? 6 is used as an operand for both the addition and division operators. outcome could be assigned either 6 or 14, depending on whether the addition operation or the division operation takes place first. The answer is 14 because the division operator has higher precedence than the addition operator.
Mathematical expressions are evaluated from left to right. When two operators share an operand, the operator with the highest precedence works first. Multiplication and division have higher precedence than addition and subtraction, so the statement above works like this:
A) 6 is divided by 3 , yielding a result of 2
B) 12 is added to 2 , yielding a result of 14

It could be diagrammed in the following way:

```
outcome = 12 + 6/3
outcome = 12 + 2
outcome = 14
```

Table 3-1 shows the precedence of the arithmetic operators. The operators at the top of the table have higher precedence than the ones below them.

Table 3-1 Precedence of Arithmetic Operators (Highest to Lowest)
(unary negation) -

* / \%
+     - 

The multiplication, division, and modulus operators have the same precedence. This is also true of the addition and subtraction operators. Table 3-2 shows some expressions with their values.

Table 3-2 Some Simple Expressions and Their Values

| Expression | Value |
| :--- | :--- |
| $5+2 * 4$ | 13 |
| $10 / 2-3$ | 2 |
| $8+12 * 2-4$ | 28 |
| $4+17 \% 2-1$ | 4 |
| $6-3 * 2+7-1$ | 6 |

## Associativity

An operator's associativity is either left to right, or right to left. If two operators sharing an operand have the same precedence, they work according to their associativity. Table 3-3 lists the associativity of the arithmetic operators. As an example, look at the following expression:

$$
5-3+2
$$

Both the - and + operators in this expression have the same precedence, and they have left to right associativity. So, the operators will work from left to right. This expression is the same as:

$$
((5-3)+2)
$$

Here is another example:
12 / 6 * 4
Because the / and * operators have the same precedence, and they have left to right associativity, they will work from left to right. This expression is the same as:

$$
((12 / 6) * 4)
$$

Table 3-3 Associativity of Arithmetic Operators

| Operator | Associativity |
| :--- | :--- |
| (unary negation) - | Right to left |
| $* / \%$ | Left to right |
| +- | Left to right |

## Grouping with Parentheses

Parts of a mathematical expression may be grouped with parentheses to force some operations to be performed before others. In the following statement, the sum of $a+b$ is divided by 4 .

```
result = (a + b) / 4;
```

Without the parentheses, however, b would be divided by 4 and the result added to a. Table 3-4 shows more expressions and their values.

Table 3-4 More Simple Expressions and Their Values

| Expression | Value |
| :--- | :--- |
| $(5+2) * 4$ | 28 |
| $10 /(5-3)$ | 5 |
| $8+12 *(6-2)$ | 56 |
| $(4+17) \% 2-1$ | 0 |
| $(6-3) *(2+7) / 3$ | 9 |

## Converting Algebraic Expressions to Programming Statements

In algebra, it is not always necessary to use an operator for multiplication. $\mathrm{C}++$, however, requires an operator for any mathematical operation. Table 3-5 shows some algebraic expressions that perform multiplication and the equivalent $\mathrm{C}++$ expressions.

Table 3-5 Algebraic and C++ Multiplication Expressions

| Algebraic Expression | Operation | C++ Equivalent |
| :--- | :--- | :--- |
| $6 B$ | 6 times $B$ | $6 * B$ |
| $(3)(12)$ | 3 times 12 | $3 * 12$ |
| $4 x y$ | 4 times x times y | $4 * x * y$ |

When converting some algebraic expressions to C++, you may have to insert parentheses that do not appear in the algebraic expression. For example, look at the following expression:
$x=\frac{a+b}{c}$
To convert this to a C++ statement, $a+b$ will have to be enclosed in parentheses:

$$
x=(a+b) / c
$$

Table 3-6 shows more algebraic expressions and their C++ equivalents.
Table 3-6 Algebraic and C++ Expressions

| Algebraic Expression | C++ Expression |
| :--- | :--- |
| $y=3 \frac{x}{2}$ | $\mathrm{y}=\mathrm{x} / 2 * 3 ;$ |
| $z=3 b c+4$ | $\mathrm{z}=3 * \mathrm{~b} * \mathrm{c}+4 ;$ |
| $a=\frac{3 x+2}{4 a-1}$ | $\mathrm{a}=(3 * \mathrm{x}+2) /(4 * \mathrm{a}-1)$ |

## No Exponents Please!

Unlike many programming languages, C++ does not have an exponent operator. Raising a number to a power requires the use of a library function. The C++ library isn't a place where you check out books, but a collection of specialized functions. Think of a library function as a "routine" that performs a specific operation. One of the library functions is called pow, and its purpose is to raise a number to a power. Here is an example of how it's used:

```
area = pow(4.0, 2.0);
```

This statement contains a call to the pow function. The numbers inside the parentheses are arguments. Arguments are data being sent to the function. The pow function always raises the first argument to the power of the second argument. In this example, 4 is raised to the power of 2 . The result is returned from the function and used in the statement where the function call appears. In this case, the value 16 is returned from pow and assigned to the variable area. This is illustrated in Figure 3-3.

Figure 3-3 The pow function

The statement area $=\operatorname{pow}(4.0,2.0)$ is equivalent to the following algebraic statement:

```
area = 4 }\mp@subsup{}{}{2
```

Here is another example of a statement using the pow function. It assigns 3 times $6^{3}$ to x :

```
x = 3 * pow(6.0, 3.0);
```

And the following statement displays the value of 5 raised to the power of 4 :

```
cout << pow(5.0, 4.0);
```

It might be helpful to think of pow as a "black box" that you plug two numbers into, and that then sends a third number out. The number that comes out has the value of the first number raised to the power of the second number, as illustrated in Figure 3-4:

Figure 3-4 The pow function as a "black box"

There are some guidelines that should be followed when the pow function is used. First, the program must include the <cmath> header file. Second, the arguments that you pass to the pow function should be doubles. Third, the variable used to store pow's return value should be defined as a double. For example, in the following statement the variable area should be a double:

```
area = pow(4.0, 2.0);
```

Program 3-5 solves a simple algebraic problem. It asks the user to enter the radius of a circle and then calculates the area of the circle. The formula is

$$
\text { Area }=\pi r^{2}
$$

which is expressed in the program as

```
area = PI * pow(radius, 2.0);
```

## Program 3-5

```
// This program calculates the area of a circle.
// The formula for the area of a circle is Pi times
// the radius squared. Pi is 3.14159.
#include <iostream>
#include <cmath> // needed for pow function
using namespace std;
int main()
{
    const double PI = 3.14159;
    double area, radius;
    cout << "This program calculates the area of a circle.\n";
    cout << "What is the radius of the circle? ";
    cin >> radius;
    area = PI * pow(radius, 2.0);
    cout << "The area is " << area << endl;
    return 0;
}
```

## Program Output with Example Input Shown in Bold

This program calculates the area of a circle. What is the radius of the circle? 10 Enter The area is 314.159

NOTE: Program 3-5 is presented as a demonstration of the pow function. In reality, there is no reason to use the pow function in such a simple operation. The math statement could just as easily be written as

```
area = PI * radius * radius;
```

The pow function is useful, however, in operations that involve larger exponents.

## In the Spotlight:

## Calculating an Average

Determining the average of a group of values is a simple calculation: You add all of the values, then divide the sum by the number of values. Although this is a straightforward calculation, it is easy to make a mistake when writing a program that calculates an average. For example, let's assume that a, b, and c are double variables. Each of the variables holds a value, and we want to calculate the average of those values. If we are careless, we might write a statement such as the following to perform the calculation:

```
average = a + b + c / 3.0;
```

Can you see the error in this statement? When it executes, the division will take place first. The value in c will be divided by 3.0 , then the result will be added to the sum of a + b. That is not the correct way to calculate an average. To correct this error, we need to put parentheses around $a+b+c$, as shown here:

```
average = (a + b + c) / 3.0;
```

Let's step through the process of writing a program that calculates an average. Suppose you have taken three tests in your computer science class, and you want to write a program that will display the average of the test scores. Here is the algorithm in pseudocode:

Get the first test score.
Get the second test score.
Get the third test score.
Calculate the average by adding the three test scores and dividing the sum by 3.
Display the average.
In the first three steps, we prompt the user to enter three test scores. Let's say we store those test scores in the double variables test1, test2, and test3. Then in the fourth step, we calculate the average of the three test scores. We will use the following statement to perform the calculation and store the result in the average variable, which is a double:

```
average = (test1 + test2 + test3) / 3.0;
```

The last step is to display the average. Program 3-6 shows the program.

## Program 3-6

```
// This program calculates the average
// of three test scores.
#include <iostream>
#include <cmath>
using namespace std;
int main()
{
    double test1, test2, test3; // To hold the scores
    double average; // To hold the average
    // Get the three test scores.
    cout << "Enter the first test score: ";
    cin >> test1;
    cout << "Enter the second test score: ";
    cin >> test2;
    cout << "Enter the third test score: ";
    cin >> test3;
    // Calculate the average of the scores.
    average = (test1 + test2 + test3) / 3.0;
    // Display the average.
    cout << "The average score is: " << average << endl;
    return 0;
}
```

## Program Output with Example Input Shown in Bold

Enter the first test score: 90 Enter
Enter the second test score: 80 Enter
Enter the third test score: 100 Enter
The average score is 90

## Checkpoint

3.7 Complete the table below by determining the value of each expression.

| Expression | Value |
| :--- | :--- |
| $6+3 * 5$ |  |
| $12 / 2-4$ |  |
| $9+14 * 2-6$ |  |
| $5+19 \% 3-1$ |  |
| $(6+2) * 3$ |  |
| $14 /(11-4)$ |  |
| $9+12 *(8-3)$ |  |
| $(6+17) \% 2-1$ |  |
| $(9-3) *(6+9) / 3$ |  |

3.8 Write C++ expressions for the following algebraic expressions:

$$
\begin{aligned}
& y=6 x \\
& a=2 b+4 c \\
& y=x^{2} \\
& g=\frac{x+2}{z^{2}} \\
& y=\frac{x^{2}}{z^{2}}
\end{aligned}
$$

3.9 Study the following program and complete the table.

```
#include <iostream>
#include <cmath>
using namespace std;
int main()
{
    double value1, value2, value3;
        cout << "Enter a number: ";
        cin >> value1;
        value2 = 2 * pow(value1, 2.0);
        value3 = 3 + value2 / 2 - 1;
        cout << value3 << endl;
        return 0;
}
```

3.10 Complete the following program skeleton so it displays the volume of a cylindrical fuel tank. The formula for the volume of a cylinder is
Volume $=\pi r^{2} h$
where
$\pi$ is 3.14159,
$r$ is the radius of the tank, and
$b$ is the height of the tank.
\#include <iostream>
\#include <cmath>
using namespace std;

```
int main()
{
    double volume, radius, height;
    cout << "This program will tell you the volume of\n";
    cout << "a cylinder-shaped fuel tank.\n";
    cout << "How tall is the tank? ";
    cin >> height;
    cout << "What is the radius of the tank? ";
    cin >> radius;
    // You must complete the program.
}
```

### 3.3 When You Mix Apples and Oranges: Type Conversion

CONCEPT: When an operator's operands are of different data types, C++ will automatically convert them to the same data type. This can affect the results of mathematical expressions.

If an int is multiplied by a float, what data type will the result be? What if a double is divided by an unsigned int? Is there any way of predicting what will happen in these instances? The answer is yes. C++ follows a set of rules when performing mathematical operations on variables of different data types. It's helpful to understand these rules to prevent subtle errors from creeping into your programs.
Just like officers in the military, data types are ranked. One data type outranks another if it can hold a larger number. For example, a float outranks an int. Table 3-7 lists the data types in order of their rank, from highest to lowest.

Table 3-7 Data Type Ranking

```
long double
doub1e
float
unsigned long long int
long long int
unsigned long int
long int
unsigned int
int
```

One exception to the ranking in Table 3-7 is when an int and a long are the same size. In that case, an unsigned int outranks long because it can hold a higher value.
When C++ is working with an operator, it strives to convert the operands to the same type. This automatic conversion is known as type coercion. When a value is converted to a higher data type, it is said to be promoted. To demote a value means to convert it to a lower data type. Let's look at the specific rules that govern the evaluation of mathematical expressions.

Rule 1: chars, shorts, and unsigned shorts are automatically promoted to int.
You will notice that char, short, and unsigned short do not appear in Table 3-7. That's because anytime they are used in a mathematical expression, they are automatically promoted to an int. The only exception to this rule is when an unsigned short holds a value larger than can be held by an int. This can happen on systems where shorts are the same size as ints. In this case, the unsigned short is promoted to unsigned int.

Rule 2: When an operator works with two values of different data types, the lower-ranking value is promoted to the type of the higher-ranking value.
In the following expression, assume that years is an int and interestRate is a float:

```
years * interestRate
```

Before the multiplication takes place, years will be promoted to a float.
Rule 3: When the final value of an expression is assigned to a variable, it will be converted to the data type of that variable.
In the following statement, assume that area is a long int, while length and width are both ints:

```
area = length * width;
```

Since length and width are both ints, they will not be converted to any other data type. The result of the multiplication, however, will be converted to long so that it can be stored in area.
Watch out for situations where an expression results in a fractional value being assigned to an integer variable. Here is an example:

```
int x, y = 4;
float z = 2.7;
x = y * z;
```

In the expression $y^{*} \mathrm{z}$, y will be promoted to f 1 oat and 10.8 will result from the multiplication. Since x is an integer, however, 10.8 will be truncated and 10 will be stored in x .

## Integer Division

When you divide an integer by another integer in C++, the result is always an integer. If there is a remainder, it will be discarded. For example, in the following code, parts is assigned the value 2.0:

```
double parts;
parts = 15 / 6;
```

Even though 15 divided by 6 is really 2.5 , the .5 part of the result is discarded because we are dividing an integer by an integer. It doesn't matter that parts is declared as a double because the fractional part of the result is discarded before the assignment takes place. In order for a division operation to return a floating-point value, at least one of the operands must be of a floating-point data type. For example, the previous code could be written as:

```
double parts;
parts = 15.0 / 6;
```

In this code, the literal value 15.0 is interpreted as a floating-point number, so the division operation will return a floating-point number. The value 2.5 will be assigned to parts.

### 3.4 Overflow and Underflow

CONCEPT: When a variable is assigned a value that is too large or too small in range for that variable's data type, the variable overflows or underflows.

Trouble can arise when a variable is being assigned a value that is too large for its type. Here is a statement where $a, b$, and $c$ are all short integers:

$$
\mathrm{a}=\mathrm{b} \text { * } \mathrm{c} \text {; }
$$

If b and c are set to large enough values, the multiplication will produce a number too big to be stored in a. To prepare for this, a should have been defined as an int, or a long int.
When a variable is assigned a number that is too large for its data type, it overflows. Likewise, assigning a value that is too small for a variable causes it to underflow. Program 3-7 shows what happens when an integer overflows or underflows. (The output shown is from a system with two-byte short integers.)

## Program 3-7

```
// This program demonstrates integer overflow and underflow.
#include <iostream>
using namespace std;
int main()
{
    // testVar is initialized with the maximum value for a short.
    short testVar = 32767;
    // Display testVar.
    cout << testVar << endl;
    // Add 1 to testVar to make it overflow.
    testVar = testVar + 1;
    cout << testVar << endl;
    // Subtract 1 from testVar to make it underflow.
    testVar = testVar - 1;
    cout << testVar << endl;
        return 0;
}
```

## Program Output

32767
-32768
32767
Typically, when an integer overflows, its contents wrap around to that data type's lowest possible value. In Program 3-7, testVar wrapped around from 32,767 to -32,768 when 1 was added to it. When 1 was subtracted from testVar, it underflowed, which caused its
contents to wrap back around to 32,767 . No warning or error message is given, so be careful when working with numbers close to the maximum or minimum range of an integer. If an overflow or underflow occurs, the program will use the incorrect number, and therefore produce incorrect results.

When floating-point variables overflow or underflow, the results depend upon how the compiler is configured. Your system may produce programs that do any of the following:

- Produce an incorrect result and continue running.
- Print an error message and immediately stop when either floating-point overflow or underflow occurs.
- Print an error message and immediately stop when floating-point overflow occurs, but store a 0 in the variable when it underflows.
- Give you a choice of behaviors when overflow or underflow occurs.

You can find out how your system reacts by compiling and running Program 3-8.

## Program 3-8

```
// This program can be used to see how your system handles
// floating-point overflow and underflow.
#include <iostream>
using namespace std;
int main()
{
    float test;
    test = 2.0e38 * 1000; // Should overflow test.
    cout << test << endl;
    test = 2.0e-38 / 2.0e38; // Should underflow test.
    cout << test << endl;
    return 0;
}
```

### 3.5 Type Casting

CONCEPT: Type casting allows you to perform manual data type conversion.
A type cast expression lets you manually promote or demote a value. The general format of a type cast expression is

```
static_cast<DataType>(Value)
```

where Value is a variable or literal value that you wish to convert, and DataType is the data type to which you wish to convert Value. Here is an example of code that uses a type cast expression:

```
double number = 3.7;
int val;
val = static_cast<int>(number);
```

This code defines two variables: number, a double, and val, an int. The type cast expression in the third statement returns a copy of the value in number, converted to an int. When a double is converted to an int, the fractional part is truncated, so this statement stores 3 in val. The original value in number is not changed, however.
Type cast expressions are useful in situations where C++ will not perform the desired conversion automatically. Program 3-9 shows an example where a type cast expression is used to prevent integer division from taking place. The statement that uses the type cast expression is

```
perMonth = static_cast<double>(books) / months;
```

## Program 3-9

```
// This program uses a type cast to avoid integer division.
#include <iostream>
using namespace std;
int main()
{
    int books; // Number of books to read
    int months; // Number of months spent reading
    double perMonth; // Average number of books per month
    cout << "How many books do you plan to read? ";
    cin >> books;
    cout << "How many months will it take you to read them? ";
    cin >> months;
    perMonth = static_cast<double>(books) / months;
    cout << "That is " << perMonth << " books per month.\n";
    return 0;
}
```

## Program Output with Example Input Shown in Bold

How many books do you plan to read? 30 Enter
How many months will it take you to read them? 7 Enter
That is 4.28571 books per month.
The variable books is an integer, but its value is converted to a double before the division takes place. Without the type cast expression in line 15 , integer division would have been performed, resulting in an incorrect answer.

WARNING! In Program 3-9, the following statement would still have resulted in integer division:
perMonth = static_cast<double>(books / months);
The result of the expression books / months is 4 . When 4 is converted to a double, it is 4.0. To prevent the integer division from taking place, one of the operands should be converted to a double prior to the division operation. This forces $\mathrm{C}++$ to automatically convert the value of the other operand to a double.

Program 3-10 further demonstrates the type cast expression.

## Program 3-10

```
// This program uses a type cast expression to print a character
// from a number.
#include <iostream>
using namespace std;
int main()
{
    int number = 65;
    // Display the value of the number variable.
    cout << number << endl;
    // Display the value of number converted to
    // the char data type.
    cout << static_cast<char>(number) << endl;
    return 0;
}
```

## Program Output

65
A
Let's take a closer look at this program. In line 8 , the int variable number is initialized with the value 65 . In line 11 , number is sent to cout, causing 65 to be displayed. In line 15 , a type cast expression is used to convert the value in number to the char data type. Recall from Chapter 2 that characters are stored in memory as integer ASCII codes. The number 65 is the ASCII code for the letter 'A', so this statement causes the letter ' A ' to be displayed.

NOTE: C++ provides several different type cast expressions. static_cast is the most commonly used type cast expression, so we will primarily use it in this book.

## Checkpoint

3.11 Assume the following variable definitions:
int $a=5, b=12 ;$
double $x=3.4, z=9.1$;
What are the values of the following expressions?
A) b / a
B) $x{ }^{*} a$
C) static_cast<double>(b / a)
D) static_cast<double>(b) / a
E) b / static_cast<double>(a)
F) static_cast<double>(b) / static_cast<double>(a)
G) b / static_cast<int>(x)
H) static_cast<int>(x) * static_cast<int>(z)
I) static_cast<int>(x * z)
J) static_cast<double>(static_cast<int>(x) * static_cast<int>(z))
3.12 Complete the following program skeleton so it asks the user to enter a character. Store the character in the variable letter. Use a type cast expression with the variable in a cout statement to display the character's ASCII code on the screen.

```
#include <iostream>
using namespace std;
int main()
{
    char letter;
    // Finish this program
    // as specified above.
    return 0;
}
```

3.13 What will the following program display?

```
#include <iostream>
using namespace std;
int main()
{
    int integer1, integer2;
    double result;
    integer1 = 19;
    integer2 = 2;
    result = integer1 / integer2;
    cout << result << endl;
        result = static_cast<double>(integer1) / integer2;
        cout << result << endl;
        result = static_cast<double>(integer1 / integer2);
        cout << result << endl;
        return 0;
}
```

### 3.6 Multiple Assignment and Combined Assignment

CONCEPT: Multiple assignment means to assign the same value to several variables with one statement.

C++ allows you to assign a value to multiple variables at once. If a program has several variables, such as $a, b, c$, and $d$, and each variable needs to be assigned a value, such as 12 , the following statement may be constructed:

$$
a=b=c=d=12 ;
$$

The value 12 will be assigned to each variable listed in the statement.*

[^1]
## Combined Assignment Operators

Quite often, programs have assignment statements of the following form:

```
number = number + 1;
```

The expression on the right side of the assignment operator gives the value of number plus 1. The result is then assigned to number, replacing the value that was previously stored there. Effectively, this statement adds 1 to number. In a similar fashion, the following statement subtracts 5 from number.

```
number = number - 5;
```

If you have never seen this type of statement before, it might cause some initial confusion because the same variable name appears on both sides of the assignment operator. Table 3-8 shows other examples of statements written this way.

Table 3-8 (Assume $x=6$ )

| Statement | What It Does | Value of x <br> After the Statement |
| :--- | :--- | :--- |
| $\mathrm{x}=\mathrm{x}+4 ;$ | Adds 4 to x | 10 |
| $\mathrm{x}=\mathrm{x}-3 ;$ | Subtracts 3 from x | 3 |
| $\mathrm{x}=\mathrm{x} * 10 ;$ | Multiplies x by 10 | 60 |
| $\mathrm{x}=\mathrm{x} / 2 ;$ | Divides x by 2 |  |
| $\mathrm{x}=\mathrm{x} \% 4$ | Makes x the remainder of $\mathrm{x} / 4$ | 3 |

These types of operations are very common in programming. For convenience, C++ offers a special set of operators designed specifically for these jobs. Table 3-9 shows the combined assignment operators, also known as compound operators, and arithmetic assignment operators.

Table 3-9 Combined Assignment Operators

| Operator | Example Usage | Equivalent to |
| :--- | :--- | :--- |
| $+=$ | $\mathrm{x}+=5 ;$ | $\mathrm{x}=\mathrm{x}+5 ;$ |
| $-=$ | $\mathrm{y}-=2 ;$ | $\mathrm{y}=\mathrm{y}-2 ;$ |
| $*=$ | $\mathrm{z} *=10 ;$ | $\mathrm{z}=\mathrm{z} * 10 ;$ |
| l= | $\mathrm{a} /=\mathrm{b} ;$ | $\mathrm{a}=\mathrm{a} / \mathrm{b} ;$ |
| $\%=$ | $\mathrm{c} \%=3 ;$ | $\mathrm{c}=\mathrm{c} \% 3 ;$ |

As you can see, the combined assignment operators do not require the programmer to type the variable name twice. Also, they give a clear indication of what is happening in the statement. Program 3-11 uses combined assignment operators.

## Program 3-11

```
1 // This program tracks the inventory of three widget stores
2 // that opened at the same time. Each store started with the
3 // same number of widgets in inventory. By subtracting the
```

## Program 3-11 (continued)

```
// number of widgets each store has sold from its inventory,
// the current inventory can be calculated.
#include <iostream>
using namespace std;
int main()
{
    int begInv, // Beginning inventory for all stores
        sold, // Number of widgets sold
        store1, // Store 1's inventory
        store2, // Store 2's inventory
        store3; l/ Store 3's inventory
    // Get the beginning inventory for al1 the stores.
    cout << "One week ago, 3 new widget stores opened\n";
    cout << "at the same time with the same beginning\n";
    cout << "inventory. What was the beginning inventory? ";
    cin >> begInv;
    // Set each store's inventory.
    store1 = store2 = store3 = begInv;
    // Get the number of widgets sold at store 1.
    cout << "How many widgets has store 1 sold? ";
    cin >> sold;
    store1 -= sold; // Adjust store 1's inventory.
    // Get the number of widgets sold at store 2.
    cout << "How many widgets has store 2 sold? ";
    cin >> sold;
    store2 -= sold; // Adjust store 2's inventory.
    // Get the number of widgets sold at store 3.
    cout << "How many widgets has store 3 sold? ";
    cin >> sold;
    store3 -= sold; // Adjust store 3's inventory.
    // Display each store's current inventory.
    cout << "\nThe current inventory of each store:\n";
    cout << "Store 1: " << store1 << endl;
    cout << "Store 2: " << store2 << endl;
    cout << "Store 3: " << store3 << endl;
    return 0;
}
```

## Program Output with Example Input Shown in Bold

One week ago, 3 new widget stores opened at the same time with the same beginning inventory. What was the beginning inventory? 100 Enter

```
How many widgets has store 1 sold? 25 Enter
How many widgets has store 2 sold? 15 Enter
How many widgets has store 3 sold? 45 Enter
The current inventory of each store:
Store 1: 75
Store 2: 85
Store 3: 55
```

More elaborate statements may be expressed with the combined assignment operators. Here is an example:

```
result *= a + 5;
```

In this statement, result is multiplied by the sum of a +5 . When constructing such statements, you must realize the precedence of the combined assignment operators is lower than that of the regular math operators. The statement above is equivalent to

```
result = result * (a + 5);
```

which is different from

```
result = result * a + 5;
```

Table 3-10 shows other examples of such statements and their assignment statement equivalencies.

Table 3-10 Example Usage of the Combined Assignment Operators

| Example Usage | Equivalent to |
| :--- | :--- |
| $x+=b+5 ;$ | $x=x+(b+5) ;$ |
| $y-=a * 2 ;$ | $y=y-(a * 2) ;$ |
| $z *=10-c ;$ | $z=z *(10-c) ;$ |
| $a /=b+c ;$ | $a=a /(b+c) ;$ |
| $c \%=d-3 ;$ | $c=c \%(d-3) ;$ |

## Checkpoint

3.14 Write a multiple assignment statement that assigns 0 to the variables tota1, subtotal, tax, and shipping.
3.15 Write statements using combined assignment operators to perform the following:
A) Add 6 to $x$.
B) Subtract 4 from amount.
C) Multiply y by 4 .
D) Divide total by 27 .
E) Store in x the remainder of x divided by 7 .
F) Add $y$ * 5 to $x$.
G) Subtract discount times 4 from total.
H) Multiply increase by salesRep times 5 .
I) Divide profit by shares minus 1000 .
3.16 What will the following program display?

```
#include <iostream>
using namespace std;
int main()
{
        int unus, duo, tres;
        unus = duo = tres = 5;
        unus += 4;
        duo *= 2;
        tres -= 4;
        unus /= 3;
        duo += tres;
        cout << unus << endl;
        cout << duo << endl;
        cout << tres << endl;
        return 0;
}
```

### 3.7 Formatting Output

CONCEPT: The cout object provides ways to format data as it is being displayed.
This affects the way data appears on the screen.
The same data can be printed or displayed in several different ways. For example, all of the following numbers have the same value, although they look different:

```
7 2 0
7 2 0 . 0
720.00000000
7.2e+2
+720.0
```

The way a value is printed is called its formatting. The cout object has a standard way of formatting variables of each data type. Sometimes, however, you need more control over the way data is displayed. Consider Program 3-12, for example, which displays three rows of numbers with a space between each one.

## Program 3-12

```
// This program displays three rows of numbers.
#include <iostream>
using namespace std;
int main()
{
    int num1 = 2897, num2 = 5, num3 = 837,
            num4 = 34, num5 = 7, num6 = 1623,
            num7 = 390, num8 = 3456, num9 = 12;
```

        // Display the first row of numbers
        cout << num1 << " " << num2 << " " << num3 << end1;
        // Display the second row of numbers
        cout << num4 << " " << num5 << " " << num6 << end1;
        // Display the third row of numbers
        cout << num7 << " " << num8 << " " << num9 << end1;
        return 0;
    20 \}

## Program Output

28975837
3471623
390345612

Unfortunately, the numbers do not line up in columns. This is because some of the numbers, such as 5 and 7 , occupy one position on the screen, while others occupy two or three positions. cout uses just the number of spaces needed to print each number.
To remedy this, cout offers a way of specifying the minimum number of spaces to use for each number. A stream manipulator, setw, can be used to establish print fields of a specified width. Here is an example of how it is used:

```
value = 23;
cout << setw(5) << value;
```

The number inside the parentheses after the word setw specifies the field width for the value immediately following it. The field width is the minimum number of character positions, or spaces, on the screen to print the value in. In the example above, the number 23 will be displayed in a field of 5 spaces. Since 23 only occupies 2 positions on the screen, 3 blank spaces will be printed before it. To further clarify how this works, look at the following statements:

```
value = 23;
cout << "(" << setw(5) << value << ")";
```

This will cause the following output:
( 23)
Notice the number occupies the last two positions in the field. Since the number did not use the entire field, cout filled the extra 3 positions with blank spaces. Because the number appears on the right side of the field with blank spaces "padding" it in front, it is said to be right-justified.
Program 3-13 shows how the numbers in Program 3-12 can be printed in columns that line up perfectly by using setw.

## Program 3-13

```
// This program displays three rows of numbers.
#include <iostream>
#include <iomanip> // Required for setw
using namespace std;
int main()
{
    int num1 = 2897, num2 = 5, num3 = 837,
            num4 = 34, num5 = 7, num6 = 1623,
            num7 = 390, num8 = 3456, num9 = 12;
    // Display the first row of numbers
    cout << setw(6) << num1 << setw(6)
            << num2 << setw(6) << num3 << endl;
        // Display the second row of numbers
        cout << setw(6) << num4 << setw(6)
            << num5 << setw(6) << num6 << endl;
        // Display the third row of numbers
        cout << setw(6) << num7 << setw(6)
            << num8 << setw(6) << num9 << endl;
        return 0;
}
```

## Program Output

| 2897 | 5 | 837 |
| ---: | ---: | ---: |
| 34 | 7 | 1623 |
| 390 | 3456 | 12 |

By printing each number in a field of 6 positions, they are displayed in perfect columns.

NOTE: A new header file, <iomanip>, is included in Program 3-13. It must be used in any program that uses setw.

Notice how a setw manipulator is used with each value, because setw only establishes a field width for the value immediately following it. After that value is printed, cout goes back to its default method of printing.

You might wonder what will happen if the number is too large to fit in the field, as in the following statement:

```
value = 18397;
cout << setw(2) << value;
```

In cases like this, cout will print the entire number. setw only specifies the minimum number of positions in the print field. Any number larger than the minimum will cause cout to override the setw value.

You may specify the field width of any type of data. Program 3-14 shows setw being used with an integer, a floating-point number, and a string object.

## Program 3-14

```
// This program demonstrates the setw manipulator being
// used with values of various data types.
#include <iostream>
#include <iomanip>
#include <string>
using namespace std;
int main()
{
    int intValue = 3928;
    double doubleValue = 91.5;
    string stringValue = "John J. Smith";
    cout << "(" << setw(5) << intValue << ")" << endl;
    cout << "(" << setw(8) << doubleValue << ")" << endl;
    cout << "(" << setw(16) << stringValue << ")" << endl;
    return 0;
}
```

## Program Output

(3928)
91.5)

John J. Smith)

Program 3-14 can be used to illustrate the following points:

- The field width of a floating-point number includes a position for the decimal point.
- The field width of a string object includes all characters in the string, including spaces.
- The values printed in the field are right-justified by default. This means they are aligned with the right side of the print field, and any blanks that must be used to pad it are inserted in front of the value.

## The setprecision Manipulator

## Formatting

 Numbers with setprecisionFloating-point values may be rounded to a number of significant digits, or precision, which is the total number of digits that appear before and after the decimal point. You can control the number of significant digits with which floating-point values are displayed by using the setprecision manipulator. Program 3-15 shows the results of a division operation displayed with different numbers of significant digits.

## Program 3-15

```
// This program demonstrates how setprecision rounds a
// floating-point value.
#include <iostream>
#include <iomanip>
using namespace std;
int main()
{
        double quotient, number1 = 132.364, number2 = 26.91;
        quotient = number1 / number2;
        cout << quotient << endl;
        cout << setprecision(5) << quotient << endl;
        cout << setprecision(4) << quotient << endl;
        cout << setprecision(3) << quotient << endl;
        cout << setprecision(2) << quotient << endl;
        cout << setprecision(1) << quotient << endl;
        return 0;
}
```

## Program Output

4.91877
4.9188
4.919
4.92
4.9

5

The first value is displayed in line 12 without the setprecision manipulator. (By default, the system in the illustration displays floating-point values with 6 significant digits.) The subsequent cout statements print the same value, but rounded to $5,4,3,2$, and 1 significant digits.

If the value of a number is expressed in fewer digits of precision than specified by setprecision, the manipulator will have no effect. In the following statements, the value of dollars only has four digits of precision, so the number printed by both cout statements is 24.51 .

```
double dollars = 24.51;
cout << dollars << endl; // Displays 24.51
cout << setprecision(5) << dollars << endl; // Displays 24.51
```

Table 3-11 shows how setprecision affects the way various values are displayed.

## Table 3-11 The setprecision Manipulator

| Number | Manipulator | Value Displayed |
| :--- | :--- | :--- |
| 28.92786 | setprecision(3) | 28.9 |
| 21 | setprecision(5) | 21 |
| 109.5 | setprecision(4) | 109.5 |
| 34.28596 | setprecision(2) | 34 |

Unlike field width, the precision setting remains in effect until it is changed to some other value. As with all formatting manipulators, you must include the header file <iomanip> to use setprecision.

Program 3-16 shows how the setw and setprecision manipulators may be combined to fully control the way floating-point numbers are displayed.

## Program 3-16

```
// This program asks for sales amounts for 3 days. The total
// sales are calculated and displayed in a table.
#include <iostream>
#include <iomanip>
using namespace std;
int main()
{
    doub1e day1, day2, day3, tota1;
    // Get the sales for each day.
    cout << "Enter the sales for day 1: ";
    cin >> day1;
    cout << "Enter the sales for day 2: ";
    cin >> day2;
    cout << "Enter the sales for day 3: ";
    cin >> day3;
    // Calculate the total sales.
    tota1 = day1 + day2 + day3;
    // Display the sales amounts.
    cout << "\nSales Amounts\n";
    cout << "------------\n";
    cout << setprecision(5);
    cout << "Day 1: " << setw(8) << day1 << end1;
    cout << "Day 2: " << setw(8) << day2 << end1;
    cout << "Day 3: " << setw(8) << day3 << end1;
    cout << "Total: " << setw(8) << total << endl;
    return 0;
}
```

Program Output with Example Input Shown in Bold
Enter the sales for day 1: $\mathbf{3 2 1 . 5 7}$ Enter
Enter the sales for day 2: 269.62 Enter
Enter the sales for day 3: 307.77 Enter
Sales Amounts
Day 1: 321.57
Day 2: 269.62
Day 3: 307.77
Total: 898.96

## The fixed Manipulator

The setprecision manipulator can sometimes surprise you in an undesirable way. When the precision of a number is set to a lower value, numbers tend to be printed in scientific notation. For example, here is the output of Program 3-16 with larger numbers being input:

## Program 3-16

## Program Output with Example Input Shown in Bold

```
Enter the sales for day 1: 145678.99 Enter
Enter the sales for day 2: 205614.85 Enter
Enter the sales for day 3: 198645.22 Enter
Sales Amounts
Day 1: 1.4568e+005
Day 2: 2.0561e+005
Day 3: 1.9865e+005
Tota1: 5.4994e+005
```

Another stream manipulator, fixed, forces cout to print the digits in fixed-point notation, or decimal. Program 3-17 shows how the fixed manipulator is used.

## Program 3-17

```
// This program asks for sales amounts for 3 days. The total
// sales are calculated and displayed in a table.
#include <iostream>
#include <iomanip>
using namespace std;
int main()
{
    doub1e day1, day2, day3, tota1;
    // Get the sales for each day.
    cout << "Enter the sales for day 1: ";
    cin >> day1;
    cout << "Enter the sales for day 2: ";
    cin >> day2;
    cout << "Enter the sales for day 3: ";
    cin >> day3;
    // Calculate the total sales.
    tota1 = day1 + day2 + day3;
```

```
22
23
24
25
26
27
28
29
30
31 }
```

## Program Output with Example Input Shown in Bold

```
Sales Amounts
Day 1: 1321.87
Day 2: 1869.26
Day 3: 1403.77
Total: 4594.90
```

Enter the sales for day 1: 1321.87 Enter
Enter the sales for day 2: 1869.26 Enter
Enter the sales for day 3: 1403.77 Enter

The statement in line 25 uses the fixed manipulator:

```
cout << setprecision(2) << fixed;
```

When the fixed manipulator is used, all floating-point numbers that are subsequently printed will be displayed in fixed-point notation, with the number of digits to the right of the decimal point specified by the setprecision manipulator.

When the fixed and setprecision manipulators are used together, the value specified by the setprecision manipulator will be the number of digits to appear after the decimal point, not the number of significant digits. For example, look at the following code:

```
double x = 123.4567;
cout << setprecision(2) << fixed << x << endl;
```

Because the fixed manipulator is used, the setprecision manipulator will cause the number to be displayed with two digits after the decimal point. The value will be displayed as 123.46.

## The showpoint Manipulator

By default, floating-point numbers are not displayed with trailing zeros, and floating-point numbers that do not have a fractional part are not displayed with a decimal point. For example, look at the following code:

```
double x = 123.4, y = 456.0;
cout << setprecision(6) << x << endl;
cout << y << endl;
```

The cout statements will produce the following output:
123.4

456
Although six significant digits are specified for both numbers, neither number is displayed with trailing zeros. If we want the numbers padded with trailing zeros, we must use the showpoint manipulator as shown in the following code:

```
double x = 123.4, y = 456.0;
cout << setprecision(6) << showpoint << x << endl;
cout << y << endl;
```

These cout statements will produce the following output:
123.400
456.000

NOTE: With most compilers, trailing zeros are displayed when the setprecision and fixed manipulators are used together.

## The 1 eft and right Manipulators

Normally output is right-justified. For example, look at the following code:

```
double x = 146.789, y = 24.2, z = 1.783;
cout << setw(10) << x << endl;
cout << setw(10) << y << endl;
cout << setw(10) << z << endl;
```

Each of the variables, $x, y$, and $z$, is displayed in a print field of 10 spaces. The output of the cout statements is
146.789
24.2
1.783

Notice each value is right-justified, or aligned to the right of its print field. You can cause the values to be left-justified by using the left manipulator, as shown in the following code.

```
double x = 146.789, y = 24.2, z = 1.783;
cout << left << setw(10) << x << endl;
cout << setw(10) << y << endl;
cout << setw(10) << z << end1;
```

The output of these cout statements is
146.789
24.2
1.783

In this case, the numbers are aligned to the left of their print fields. The left manipulator remains in effect until you use the right manipulator, which causes all subsequent output to be right-justified.

Table 3-12 summarizes the manipulators we have discussed.

Table 3-12 Stream Manipulators

| Stream Manipulator | Description |
| :--- | :--- |
| setw $(n)$ | Establishes a print field of $n$ spaces. |
| fixed | Displays floating-point numbers in fixed-point notation. |
| showpoint | Causes a decimal point and trailing zeros to be displayed, <br> even if there is no fractional part. |
| setprecision $(n)$ | Sets the precision of floating-point numbers. |
| left | Causes subsequent output to be left-justified. |
| right | Causes subsequent output to be right-justified. |

## Checkpoint

3.17 Write cout statements with stream manipulators that perform the following:
A) Display the number 34.789 in a field of nine spaces with two decimal places of precision.
B) Display the number 7.0 in a field of five spaces with three decimal places of precision.
The decimal point and any trailing zeros should be displayed.
C) Display the number $5.789 \mathrm{e}+12$ in fixed-point notation.
D) Display the number 67 left-justified in a field of seven spaces.
3.18 The following program will not compile because the lines have been mixed up:

```
#include <iomanip>
}
cout << person << endl;
string person = "Wolfgang Smith";
int main()
cout << person << endl;
{
#include <iostream>
return 0;
cout << left;
using namespace std;
cout << setw(20);
cout << right;
```

When the lines are properly arranged, the program should display the following:
Wolfgang Smith
Wolfgang Smith
Rearrange the lines in the correct order. Test the program by entering it on the computer, compiling it, and running it.
3.19 The following program skeleton asks for an angle in degrees and converts it to radians. The formatting of the final output is left to you.

```
#include <iostream>
#include <iomanip>
using namespace std;
int main()
{
    const double PI = 3.14159;
    double degrees, radians;
    cout << "Enter an angle in degrees and I will convert it\n";
    cout << "to radians for you: ";
    cin >> degrees;
    radians = degrees * PI / 180;
    // Display the value in radians left-justified, in fixed
    // point notation, with 4 places of precision, in a field
    // 5 spaces wide, making sure the decimal point is always
    // displayed.
    return 0;
}
```

### 3.8 Working with Characters and string Objects

CONCEPT: Special functions exist for working with characters and string objects.
Although it is possible to use cin with the >> operator to input strings, it can cause problems of which you need to be aware. When cin reads input, it passes over and ignores any leading whitespace characters (spaces, tabs, or line breaks). Once it comes to the first nonblank character and starts reading, it stops reading when it gets to the next whitespace character. Program 3-18 illustrates this problem.

## Program 3-18

```
// This program illustrates a problem that can occur if
// cin is used to read character data into a string object.
#include <iostream>
#include <string>
using namespace std;
int main()
{
    string name;
    string city;
    cout << "Please enter your name: ";
    cin >> name;
    cout << "Enter the city you live in: ";
    cin >> city;
```

```
    cout << "Hello, " << name << endl;
    cout << "You live in " << city << endl;
    return 0;
}
```

## Program Output with Example Input Shown in Bold

```
Please enter your name: Kate Smith Enter
Enter the city you live in: Hello, Kate
You live in Smith
```

Notice the user was never given the opportunity to enter the city. In the first input statement, when cin came to the space between Kate and Smi th, it stopped reading, storing just Kate as the value of name. In the second input statement, cin used the leftover characters it found in the keyboard buffer and stored Smith as the value of city.

To work around this problem, you can use a C++ function named getline. The getline function reads an entire line, including leading and embedded spaces, and stores it in a string object. The getline function looks like the following, where cin is the input stream we are reading from and inputLine is the name of the string object receiving the input:

```
getline(cin, inputLine);
```

Program 3-19 illustrates using the get 1 ine function.

## Program 3-19

```
// This program demonstrates using the getline function
// to read character data into a string object.
#include <iostream>
#include <string>
using namespace std;
int main()
{
    string name;
    string city;
    cout << "Please enter your name: ";
    getline(cin, name);
    cout << "Enter the city you live in: ";
    getline(cin, city);
    cout << "Hello, " << name << endl;
    cout << "You live in " << city << endl;
    return 0;
}
```

## Program Output with Example Input Shown in Bold

## Please enter your name: Kate Smith Enter

Enter the city you live in: Raleigh Enter
Hello, Kate Smith
You live in Raleigh

## Inputting a Character

Sometimes you want to read only a single character of input. For example, some programs display a menu of items for the user to choose from. Often the selections are denoted by the letters A, B, C, and so forth. The user chooses an item from the menu by typing a character. The simplest way to read a single character is with cin and the >> operator, as illustrated in Program 3-20.

## Program 3-20

```
    // This program reads a single character into a char variable.
```

    \#include <iostream>
    using namespace std;
    int main()
    \{
        char ch;
        cout << "Type a character and press Enter: ";
        cin >> ch;
        cout << "You entered " << ch << endl;
        return 0;
    \}

# Program Output with Example Input Shown in Bold 

```
Type a character and press Enter: A Enter
```

You entered A

## Using cin.get

As with string input, however, there are times when using cin >> to read a character does not do what you want. For example, because it passes over all leading whitespace, it is impossible to input just a blank or Enter with cin >>. The program will not continue past the cin statement until some character other than the spacebar, tab key, or Enter key has been pressed. (Once such a character is entered, the Enter key must still be pressed before the program can continue to the next statement.) Thus, programs that ask the user to "Press the Enter key to continue." cannot use the >> operator to read only the pressing of the Enter key.

In those situations, the cin object has a built-in function named get that is helpful. Because the get function is built into the cin object, we say that it is a member function of cin. The get member function reads a single character, including any whitespace character. If the program needs to store the character being read, the get member function can be called in either of the following ways. In both examples, assume ch is the name of a char variable into which the character is being read.

```
cin.get(ch);
ch = cin.get();
```

If the program is using the cin.get function simply to pause the screen until the Enter key is pressed and does not need to store the character, the function can also be called like this:

```
cin.get();
```

Program 3-21 illustrates all three ways to use the cin.get function.

## Program 3-21

```
// This program demonstrates three ways
// to use cin.get() to pause a program.
#include <iostream>
using namespace std;
int main()
{
        char ch;
        cout << "This program has paused. Press Enter to continue.";
        cin.get(ch);
        cout << "It has paused a second time. Please press Enter again.";
        ch = cin.get();
        cout << "It has paused a third time. Please press Enter again.";
        cin.get();
        cout << "Thank you!";
        return 0;
}
```

## Program Output with Example Input Shown in Bold

This program has paused. Press Enter to continue. Enter
It has paused a second time. Please press Enter again. Enter
It has paused a third time. Please press Enter again. Enter
Thank you!

## Mixing cin $\gg$ and cin.get

Mixing cin >> with cin.get can cause an annoying and hard-to-find problem. For example, look at Program 3-22.

## Program 3-22

```
// This program demonstrates a problem that occurs
// when you mix cin >> with cin.get().
#include <iostream>
using namespace std;
int main()
{
    char ch; // Define a character variable
    int number; // Define an integer variable
```

```
Program 3-22 (continued)
    cout << "Enter a number: ";
    cin >> number; // Read an integer
    cout << "Enter a character: ";
    ch = cin.get(); // Read a character
    cout << "Thank You!\n";
    return 0;
    }
```

Program Output with Example Input Shown in Bold
Enter a number: 100 Enter
Enter a character: Thank You!

When this program runs, line 12 lets the user enter a number, but it appears as though the statement in line 14 is skipped. This happens because cin >> and cin.get use slightly different techniques for reading data.

In the example run of the program, when line 12 executed, the user entered 100 and pressed the Enter key. Pressing the Enter key causes a newline character ('\n') to be stored in the keyboard buffer, as shown in Figure 3-5. The cin >> statement in line 12 begins reading the data that the user entered, and stops reading when it comes to the newline character. This is shown in Figure 3-6. The newline character is not read, but remains in the keyboard buffer.

Figure 3-5 Contents of the keyboard buffer

Figure 3-6 cin stops reading at the newline character
Keyboard buffer
cin stops reading here, but does not read the $\backslash n$ character.

When the cin.get function in line 14 executes, it begins reading the keyboard buffer where the previous input operation stopped. That means cin.get reads the newline character, without giving the user a chance to enter any more input. You can remedy this situation by using the cin.ignore function, described in the following section.

## Using cin.ignore

To solve the problem previously described, you can use another of the cin object's member functions named ignore. The cin.ignore function tells the cin object to skip one or more characters in the keyboard buffer. Here is its general form:

```
cin.ignore(n, c);
```

The arguments shown in the parentheses are optional. If used, $n$ is an integer and $c$ is a character. They tell cin to skip $n$ number of characters, or until the character $c$ is encountered. For example, the following statement causes cin to skip the next 20 characters or until a newline is encountered, whichever comes first:

```
cin.ignore(20,'\n');
```

If no arguments are used, cin will skip only the very next character. Here's an example:

```
cin.ignore();
```

Program 3-23, which is a modified version of Program 3-22, demonstrates the function. Notice a call to cin. ignore has been inserted in line 13, right after the cin >> statement.

## Program 3-23

```
// This program successfully uses both
// cin >> and cin.get() for keyboard input.
#include <iostream>
using namespace std;
int main()
{
    char ch;
    int number;
    cout << "Enter a number: ";
    cin >> number;
    cin.ignore(); // Skip the newline character
    cout << "Enter a character: ";
    ch = cin.get();
    cout << "Thank You!\n";
    return 0;
}
```

## Program Output with Example Input Shown in Bold

Enter a number: 100 Enter
Enter a character: Z Enter
Thank You!

## string Member Functions and Operators

C++ string objects also have a number of member functions. For example, if you want to know the length of the string that is stored in a string object, you can call the object's length member function. Here is an example of how to use it:

```
string state = "Texas";
int size = state.length();
```

The first statement creates a string object named state and initializes it with the string "Texas". The second statement defines an int variable named size and initializes it with the length of the string in the state object. After this code executes, the size variable will hold the value 5 .

Certain operators also work with string objects. One of them is the + operator. You have already encountered the + operator to add two numeric quantities. Because strings cannot be added, when this operator is used with string operands it concatenates them, or joins them together. Assume we have the following definitions and initializations in a program:

```
string greeting1 = "Hello ";
string greeting2;
string name1 = "World";
string name2 = "People";
```

The following statements illustrate how string concatenation works:

```
greeting2 = greeting1 + name1; // greeting2 now holds "He1lo Wor1d"
greeting1 = greeting1 + name2; // greeting1 now holds "Hello People"
```

Notice the string stored in greeting1 has a blank as its last character. If the blank were not there, greeting2 would have been assigned the string "HelloWorld".

The last statement in the previous example could also have been written using the += combined assignment operator, to achieve the same result:

```
greeting1 += name2;
```

You will learn about other useful string member functions and operators in Chapter 10.

### 3.9 More Mathematical Library Functions

CONCEPT: The C++ runtime library provides several functions for performing complex mathematical operations.

Earlier in this chapter, you learned to use the pow function to raise a number to a power. The C++ library has numerous other functions that perform specialized mathematical operations. These functions are useful in scientific and special-purpose programs. Table 3-13 shows several of these, each of which requires the <cmath> header file.

Table 3-13 <cmath> Library Functions

| Function | Example | Description |
| :---: | :---: | :---: |
| abs | $y=\operatorname{abs}(x) ;$ | Returns the absolute value of the argument. The argument and the return value are integers. |
| cos | $y=\cos (x) ;$ | Returns the cosine of the argument. The argument should be an angle expressed in radians. The return type and the argument are doubles. |
| exp | $y=\exp (x) ;$ | Computes the exponential function of the argument, which is x . The return type and the argument are doubles. |
| fmod | $y=f m o d(x, z) ;$ | Returns, as a double, the remainder of the first argument divided by the second argument. Works like the modulus operator, but the arguments are doubles. (The modulus operator only works with integers.) Take care not to pass zero as the second argument. Doing so would cause division by zero. |
| 10 g | $y=\log (x) ;$ | Returns the natural logarithm of the argument. The return type and the argument are doubles. |
| $\log 10$ | $y=10 \mathrm{l} 10(x) ;$ | Returns the base-10 logarithm of the argument. The return type and the argument are doubles. |
| round | $y=\operatorname{round}(x)$ | The argument, $x$, can be a double, a float, or a long double. Returns the value of $x$ rounded to the nearest whole number. For example, if x is 2.8 , the function returns 3.0 , or if x is 2.1 , the function returns 2.0. The return type is the same as the type of the argument. |
| sin | $y=\sin (x) ;$ | Returns the sine of the argument. The argument should be an angle expressed in radians. The return type and the argument are doubles. |
| sqrt | $y=\operatorname{sqrt}(x) ;$ | Returns the square root of the argument. The return type and argument are doubles. |
| tan | $y=\tan (x) ;$ | Returns the tangent of the argument. The argument should be an angle expressed in radians. The return type and the argument are doubles. |

Each of these functions is as simple to use as the pow function. The following program segment demonstrates the sqrt function, which returns the square root of a number:

```
cout << "Enter a number: ";
cin >> num;
s = sqrt(num);
cout << "The square root of " << num << " is " << s << endl;
```

Here is the output of the program segment, with 25 as the number entered by the user:
Enter a number: 25
The square root of 25 is 5
Program 3-24 shows the sqrt function being used to find the hypotenuse of a right triangle. The program uses the following formula, taken from the Pythagorean theorem:
$c=\sqrt{a^{2}+b^{2}}$
In the formula, $c$ is the length of the hypotenuse, and $a$ and $b$ are the lengths of the other sides of the triangle.

## Program 3-24

// This program asks for the lengths of the two sides of a
// right triangle. The length of the hypotenuse is then
// calculated and displayed.
\#include <iostream>
\#include <iomanip> // For setprecision
\#include <cmath> // For the sqrt and pow functions using namespace std;
int main()
\{
double a, b, c;
cout << "Enter the length of side a: ";
cin >> a;
cout << "Enter the length of side b: ";
cin >> b;
$c=\operatorname{sqrt}(\operatorname{pow}(a, 2.0)+\operatorname{pow}(b, 2.0))$;
cout << "The length of the hypotenuse is ";
cout << setprecision(2) << c << endl; return 0;
\}

## Program Output with Example Input Shown in Bold

```
Enter the length of side a: 5.0 Enter
Enter the length of side b: 12.0 Enter
The length of the hypotenuse is 13
```

The following statement, taken from Program 3-24, calculates the square root of the sum of the squares of the triangle's two sides:

```
c = sqrt(pow(a, 2.0) + pow(b, 2.0));
```

Notice the following mathematical expression is used as the sqrt function's argument:
pow(a, 2.0) + pow(b, 2.0)
This expression calls the pow function twice: once to calculate the square of a, and again to calculate the square of $b$. These two squares are then added together, and the sum is sent to the sqrt function.

## Random Numbers

Random numbers are useful for lots of different programming tasks. The following are just a few examples:

- Random numbers are commonly used in games. For example, computer games that let the player roll dice use random numbers to represent the values of the dice.
- Programs that show cards being drawn from a shuffled deck use random numbers to represent the face values of the cards.
- Random numbers are useful in simulation programs. In some simulations, the computer must randomly decide how a person, animal, insect, or other living being will behave. Formulas can be constructed in which a random number is used to determine various actions and events that take place in the program.
- Random numbers are useful in statistical programs that must randomly select data for analysis.
- Random numbers are commonly used in computer security to encrypt sensitive data.

The C++ library has a function, rand(), that you can use to generate random numbers. (The rand () function requires the <cstdlib> header file.) The number returned from the function is an int. Here is an example of its usage:

```
y = rand();
```

After this statement executes, the variable $y$ will contain a random number. In actuality, the numbers produced by rand()are pseudorandom. The function uses an algorithm that produces the same sequence of numbers each time the program is repeated on the same system. For example, suppose the following statements are executed:

```
cout << rand() << endl;
cout << rand() << endl;
cout << rand() << endl;
```

The three numbers displayed will appear to be random, but each time the program runs, the same three values will be generated. In order to randomize the results of rand(), the srand() function must be used. srand() accepts an unsigned int argument, which acts as a seed value for the algorithm. By specifying different seed values, rand() will generate different sequences of random numbers.
A common practice for getting unique seed values is to call the time function, which is part of the standard library. The time function returns the number of seconds that have elapsed since midnight, January 1, 1970. The time function requires the <ctime> header file, and you pass 0 as an argument to the function. Program 3-25 demonstrates this. The program should generate three different random numbers each time it is executed.

## Program 3-25

```
// This program demonstrates random numbers.
#include <iostream>
#include <cstdlib> // For rand and srand
#include <ctime> // For the time function
using namespace std;
int main()
{
    // Get the system time.
        unsigned seed = time(0);
        // Seed the random number generator.
        srand(seed);
```

## Program 3-25 (continued)

```
15 // Display three random numbers.
16 cout << rand() << endl;
17 cout << rand() << endl;
18 cout << rand() << endl;
19 return 0;
20 }
```

## Program Output

23861
20884
21941

If you wish to limit the range of the random number, use the following formula:

```
y = (rand() % (maxValue - minValue + 1)) + minValue;
```

In the formula, minValue is the lowest number in the range, and maxValue is the highest number in the range. For example, the following code assigns a random number in the range of 1 through 100 to the variable y :

```
const int MIN_VALUE = 1;
const int MAX_VALUE = 100;
y = (rand() % (MAX_VALUE - MIN_VALUE + 1)) + MIN_VALUE;
```

As another example, the following code assigns a random number in the range of 100 through 200 to the variable y :

```
const int MIN_VALUE = 100;
const int MAX_VALUE = 200;
y = (rand() % (MAX_VALUE - MIN_VALUE + 1)) + MIN_VALUE;
```

The following In the Spotlight section demonstrates how to use random numbers to simulate rolling dice.

## In the Spotlight:

## Using Random Numbers

Dr. Kimura teaches an introductory statistics class and has asked you to write a program that he can use in class to simulate the rolling of dice. The program should randomly generate two numbers in the range of 1 through 6 and display them. Program 3-26 shows the program, with three examples of program output.

## Program 3-26

```
// This program simulates rolling dice.
#include <iostream>
#include <cstdlib> // For rand and srand
#include <ctime> // For the time function
using namespace std;
```

```
int main()
{
    // Constants
    const int MIN_VALUE = 1; // Minimum die value
    const int MAX_VALUE = 6; // Maximum die value
    // Variables
    int die1; // To hold the value of die #1
    int die2; // To hold the value of die #2
    // Get the system time.
    unsigned seed = time(0);
    // Seed the random number generator.
    srand(seed);
    cout << "Rolling the dice...\n";
    die1 = (rand() % (MAX_VALUE - MIN_VALUE + 1)) + MIN_VALUE;
    die2 = (rand() % (MAX_VALUE - MIN_VALUE + 1)) + MIN_VALUE;
    cout << die1 << endl;
    cout << die2 << endl;
        return 0;
}
```

## Checkpoint

3.20 Write a short description of each of the following functions:

| cos | $\log$ | sin |
| :--- | :--- | :--- |
| exp | $\log 10$ | sqrt |
| fmod | pow | tan |

3.21 Assume the variables angle1 and ang1e2 hold angles stored in radians. Write a statement that adds the sine of angle1 to the cosine of angle2 and stores the result in the variable $x$.
3.22 To find the cube root (the third root) of a number, raise it to the power of $1 / 3$. To find the fourth root of a number, raise it to the power of $1 / 4$. Write a statement that will find the fifth root of the variable x and store the result in the variable y .
3.23 The cosecant of the angle $a$ is

$$
\frac{1}{\sin a}
$$

Write a statement that calculates the cosecant of the angle stored in the variable $a$, and stores it in the variable $y$.

### 3.10 Focus on Debugging: Hand Tracing a Program

Hand tracing is a debugging process where you pretend that you are the computer executing a program. You step through each of the program's statements one by one. As you look at a statement, you record the contents that each variable will have after the statement executes. This process is often helpful in finding mathematical mistakes and other logic errors.

To hand trace a program, you construct a chart with a column for each variable. The rows in the chart correspond to the lines in the program. For example, Program 3-27 is shown with a hand trace chart. The program uses the following four variables: num1, num2, num3, and avg. Notice the hand trace chart has a column for each variable, and a row for each line of code in function main.

## Program 3-27

```
// This program asks for three numbers, then
// displays the average of the numbers.
#include <iostream>
using namespace std;
int main()
{
    double num1, num2, num3, avg;
    cout << "Enter the first number: ";
    cin >> num1;
    cout << "Enter the second number: ";
    cin >> num2;
    cout << "Enter the third number: ";
    cin >> num3;
    avg = num1 + num2 + num3 / 3;
    cout << "The average is " << avg << endl;
    return 0;
\begin{tabular}{|l|l|l|l|}
\multicolumn{1}{l}{ num1 } & \multicolumn{1}{c}{ num2 } & \multicolumn{1}{c}{ num3 } & \multicolumn{1}{c}{ avg } \\
\hline & & & \\
\hline & & & \\
\hline & & & \\
\hline & & & \\
\hline & & & \\
\hline & & & \\
\hline & & & \\
\hline & & & \\
\hline & & & \\
\hline & & & \\
\hline
\end{tabular}
```

\}

This program, which asks the user to enter three numbers and then displays the average of the numbers, has a bug. It does not display the correct average. The output of a sample session with the program follows.

```
Program Output with Example Input Shown in Bold
Enter the first number: 10 Enter
Enter the second number: 20 Enter
Enter the third number: 30 Enter
The average is 40
```

The correct average of 10,20 , and 30 is 20 , not 40 . To find the error, we will hand trace the program. To hand trace this program, you step through each statement, observing the operation that is taking place, then record the contents of the variables after the statement executes. After the hand trace is complete, the chart will appear as follows. We have written question marks in the chart where we do not know the contents of a variable.

## Program 3-27 (with hand trace chart filled)

```
// This program asks for three numbers, then
// displays the average of the numbers.
#include <iostream>
using namespace std;
int main()
{
    double num1, num2, num3, avg;
    cout << "Enter the first number: ";
    cin >> num1;
    cout << "Enter the second number: ";
    cin >> num2;
    cout << "Enter the third number: ";
    cin >> num3;
    avg = num1 + num2 + num3 / 3;
    cout << "The average is " << avg << endl;
    return 0;
    }
```

Do you see the error? By examining the statement that performs the math operation in line 14, we find a mistake. The division operation takes place before the addition operations, so we must rewrite that statement as

```
avg = (num1 + num2 + num3) / 3;
```

Hand tracing is a simple process that focuses your attention on each statement in a program. Often this helps you locate errors that are not obvious.

### 3.11 Focus on Problem Solving: A Case Study

General Crates, Inc. builds custom-designed wooden crates. With materials and labor, it costs GCI $\$ 0.23$ per cubic foot to build a crate. In turn, they charge their customers $\$ 0.50$ per cubic foot for the crate. You have been asked to write a program that calculates the volume (in cubic feet), cost, customer price, and profit of any crate GCI builds.

## Variables

Table 3-14 shows the named constants and variables needed.

Table 3-14 Named Constants and Variables

| Constant or Variable | Description |
| :--- | :--- |
| COST_PER_CUBIC_FOOT | A named constant, declared as a double and initialized with the <br> value 0.23. This represents the cost to build a crate, per cubic foot. |
| CHARGE_PER_CUBIC_FOOT | A named constant, declared as a double and initialized with the value <br> 0.5. This represents the amount charged for a crate, per cubic foot. <br> length <br> A double variable to hold the length of the crate, which is input by <br> the user. |
| width | A double variable to hold the width of the crate, which is input by <br> the user. |
| height | A double variable to hold the height of the crate, which is input by <br> the user. |
| volume | A double variable to hold the volume of the crate. The value <br> stored in this variable is calculated. |
| cost | A double variable to hold the cost of building the crate. The value <br> stored in this variable is calculated. |
| charge | A double variable to hold the amount charged to the customer for <br> the crate. The value stored in this variable is calculated. |
| profit | A double variable to hold the profit GCI makes from the crate. <br> The value stored in this variable is calculated. |

## Program Design

The program must perform the following general steps:

1. Ask the user to enter the dimensions of the crate (the crate's length, width, and height).
2. Calculate the crate's volume, the cost of building the crate, the customer's charge, and the profit made.
3. Display the data calculated in Step 2.

A general hierarchy chart for this program is shown in Figure 3-7.

Figure 3-7 Hierarchy chart for the program

The "Get Crate Dimensions" step is shown in greater detail in Figure 3-8.
Figure 3-8 Hierarchy chart for the "Get Crate Dimensions" step

The "Calculate Volume, Cost, Customer Charge, and Profit" step is shown in greater detail in Figure 3-9.

Figure 3-9 Hierarchy chart for the "Calculate Volume, Cost, Customer Charge, and Profit" step

The "Display Calculated Data" step is shown in greater detail in Figure 3-10.
Figure 3-10 Hierarchy chart for the "Display Calculated Data" step

Pseudocode for the program is as follows:

```
Ask the user to input the crate's length.
Ask the user to input the crate's width.
Ask the user to input the crate's height.
Calculate the crate's volume.
Calculate the cost of building the crate.
Calculate the customer's charge for the crate.
Calculate the profit made from the crate.
Display the crate's volume.
Display the cost of building the crate.
Display the customer's charge for the crate.
Display the profit made from the crate.
```

## Calculations

The following formulas will be used to calculate the crate's volume, cost, charge, and profit:
volume $=$ length $\times$ width $\times$ height
cost $=$ volume $\times 0.23$
charge $=$ volume $\times 0.5$
profit $=$ charge - cost

## The Program

The last step is to expand the pseudocode into the final program, which is shown in Program 3-28.

## Program 3-28

```
// This program is used by General Crates, Inc. to calculate
// the volume, cost, customer charge, and profit of a crate
// of any size. It calculates this data from user input, which
// consists of the dimensions of the crate.
#include <iostream>
#include <iomanip>
using namespace std;
int main()
{
    // Constants for cost and amount charged
    const double COST_PER_CUBIC_FOOT = 0.23;
    const double CHARGE_PER_CUBIC_FOOT = 0.5;
    // Variables
    double length, // The crate's length
        width, // The crate's width
        height, // The crate's height
        volume, // The volume of the crate
        cost, // The cost to build the crate
```

```

```

## Program Output with Example Input Shown in Bold

Enter the dimensions of the crate (in feet):
Length: 10 Enter
Width: 8 Enter
Height: 4 Enter
The volume of the crate is 320.00 cubic feet.
Cost to build: \$73.60
Charge to customer: \$160.00
Profit: \$86.40

## Program Output with Different Example Input Shown in Bold

Enter the dimensions of the crate (in feet):
Length: 12.5 Enter
Width: 10.5 Enter
Height: 8 Enter
The volume of the crate is 1050.00 cubic feet.
Cost to build: \$241.50
Charge to customer: \$525.00
Profit: \$283.50

## Review Questions and Exercises

## Short Answer

1. Assume that the following variables are defined:
```
int length;
double breadth;
```

What will be the values in length and breadth, if the user enters 9.5 and 10.5 in response to the statement, cin >> length >> breadth?
2. Assume a string object has been defined as follows:

```
string description;
```

A) Write a cin statement that reads in a one-word string.
B) Write a statement that reads in a string that can contain multiple words separated by blanks.
3. What header files must be included in the following program?

```
int main()
{
    double amount = 89.7;
    cout << showpoint << fixed;
    cout << setw(8) << amount << endl;
    return 0;
}
```

4. Complete the following table by determining the value of each expression.

| Expression | Value |
| :--- | :--- |
| $28 / 4-2$ |  |
| $6+12 * 2-8$ |  |
| $4+8 * 2$ |  |
| $6+17 \% 3-2$ |  |
| $2+22 *(9-7)$ |  |
| $(8+7) * 2$ |  |
| $(16+7) \% 2-1$ |  |
| $12 /(10-6)$ |  |
| $(19-3) *(2+2) / 4$ |  |

5. Write C++ expressions for the following algebraic expressions:
$a=12 x$
$z=5 x+14 y+6 k$
$y=x^{4}$
$g=\frac{h+12}{4 k}$
$c=\frac{a^{3}}{b^{2} k^{4}}$
6. Assume a program has the following variable definitions:
int units;
float mass;
double weight;
and the following statement:
```
weight = mass * units;
```

Which automatic data type conversion will take place?
A) mass is demoted to an int, units remains an int, and the result of mass * units is an int.
B) units is promoted to a float, mass remains a float, and the result of mass * units is a float.
C) units is promoted to a float, mass remains a float, and the result of mass * units is a double.
7. Assume a program has the following variable definitions:
int $a, b=2$;
float $c=4.2$;
and the following statement:
$\mathrm{a}=\mathrm{b}$ * c ;
What value will be stored in a?
A) 8.4
B) 8
C) 0
D) None of the above
8. Assume qty and salesReps are both integers. Use a type cast expression to rewrite the following statement so it will no longer perform integer division.

```
unitsEach = qty / salesReps;
```

9. Rewrite the following variable definition so that the variable is a named constant.
int rate;
10. Complete the following table by providing statements with combined assignment operators for the right-hand column. The statements should be equivalent to the statements in the left-hand column.

| Statements with <br> Assignment Operator | Statements with <br> Combined Assignment Operator |
| :--- | :--- |
| $\mathrm{x}=\mathrm{x}+5 ;$ |  |
| total $=$ tota1 + subtota1; |  |
| dist $=$ dist $/$ rep; |  |
| pp1 $=$ pp1 * period; |  |
| inv $=$ inv - shrinkage; |  |
| num $=$ num \% 2; |  |

11. Write a multiple assignment statement that can be used instead of the following group of assignment statements:
```
east = 1;
west = 1;
north = 1;
south = 1;
```

12. Write a cout statement so the variable divSales is displayed in a field of 8 spaces, in fixed-point notation, with a precision of 2 decimal places. The decimal point should always be displayed.
13. Write a cout statement so the variable totalAge is displayed in a field of 12 spaces, in fixed-point notation, with a precision of 4 decimal places.
14. A variable velocity has a value of 180.67245612456 . Write a cout statement to display it in a field of six spaces left-justified. Write another cout statement to display it in 18 spaces with a precision of 12 decimal spaces, in fixed notation, with trailing zeros.

## Fill-in-the-Blank

15. The $\qquad$ library function returns the cosine of an angle.
16. The $\qquad$ library function returns the sine of an angle.
17. The $\qquad$ library function returns the tangent of an angle.
18. The $\qquad$ library function returns the exponential function of a number.
19. The $\qquad$ function generates a random number.
20. The $\qquad$ library function returns the natural logarithm of a number.
21. Stream manipulators are used for formatting the $\qquad$ of a program.
22. The $\qquad$ library function returns the value of a number raised to a power.
23. $\qquad$ is a debugging process that simulates execution of a program by the computer.
24. The $\qquad$ file must be included in a program that uses the mathematical functions.

## Algorithm Workbench

25. A retail store grants its customers a maximum amount of credit. Each customer's available credit is his or her maximum amount of credit minus the amount of credit used. Write a pseudocode algorithm for a program that asks for a customer's maximum amount of credit and amount of credit used. The program should then display the customer's available credit.
After you write the pseudocode algorithm, convert it to a complete C++ program.
26. Write a pseudocode algorithm for a program that calculates the total of a retail sale. The program should ask for the amount of the sale and the sales tax rate. The sales tax rate should be entered as a floating-point number. For example, if the sales tax rate is 6 percent, the user should enter 0.06 . The program should display the amount of sales tax and the total of the sale.
After you write the pseudocode algorithm, convert it to a complete C++ program.
27. Write a pseudocode algorithm for a program that asks the user to enter a golfer's score for three games of golf, and then displays the average of the three scores.
After you write the pseudocode algorithm, convert it to a complete C++ program.

## Find the Errors

Each of the following programs has some errors. Locate as many as you can.

```
28. using namespace std;
    int main ()
    {
        doub1e number1, number2, sum;
        Cout << "Enter a number: ";
        Cin << number1;
        Cout << "Enter another number: ";
        Cin << number2;
        number1 + number2 = sum;
        Cout "The sum of the two numbers is " << sum
        return 0;
    }
```

29. \#include <iostream>
using namespace std;
int main()
\{
int number1, number2;
float quotient;
cout << "Enter two numbers and I will divide\n";
cout << "the first by the second for you. \n";
cin >> number1, number2;
quotient = float<static_cast>(number1) / number2;
cout << quotient
return 0;
\}
30. \#include <iostream>;
using namespace std;
int main()
\{
const int number1, number2, product;
cout << "Enter two numbers and I will multiply\n";
cout << "them for you. ln ";
cin >> number1 >> number2;
product $=$ number1 * number2;
cout << product
return 0;
\}
```
31. #include <iostream>;
    using namespace std;
    main
    {
        int number1, number2;
        cout << "Enter two numbers and I will multiply\n"
        cout << "them by 50 for you.\n"
        cin >> number1 >> number2;
        number1 =* 50;
        number2 =* 50;
        cout << number1 << " " << number2;
        return 0;
    }
32. #include <iostream>;
    using namespace std;
    main
    {
        double number, half;
        cout << "Enter a number and I will divide it\n"
        cout << "in half for you.\n"
        cin >> number1;
        ha1f =/ 2;
        cout << fixedpoint << showpoint << half << endl;
        return 0;
    }
33. #include <iostream>;
    using namespace std
    int main()
    {
        double number, sqrtnumber;
    cout << "Enter any number: ";
    cin << number;
    cout << "Square Root = << " sqrt(number) << endl;
    return 0;
    }
```

## Predict the Output

What will each of the following programs display? (Some should be hand traced and require a calculator.)
34. (Assume the user enters 38700. Use a calculator.)
\#include <iostream>
using namespace std;

```
    int main()
{
    double salary, monthly;
    cout << "What is your annual salary? ";
    cin >> salary;
    month1y = static_cast<int>(salary) / 12;
    cout << "Your monthly wages are " << monthly << endl;
    return 0;
}
35. #include <iostream>
using namespace std;
int main()
{
    doub7e x=5, y=7.5;
    int z;
    x += 1;
    y -= 1;
    z = y - x;
    cout << x << " " << y << " " << z << endl;
    return 0;
}
36. (Assume the user enters George Washington.)
\#include <iostream>
#include <iomanip>
#include <string>
using namespace std;
```

```
int main()
```

int main()
{
{
string userInput;
string userInput;
cout << "What is your name? ";
cout << "What is your name? ";
getline(cin, userInput);
getline(cin, userInput);
cout << "Hello " << userInput << endl;
cout << "Hello " << userInput << endl;
return 0;
return 0;
}
}
37. (Assume the user enters 36720152 . Use a calculator.)

```
```

\#include <iostream>

```
#include <iostream>
#include <iomanip>
using namespace std;
int main()
{
    1ong seconds;
    double minutes, hours, days, months, years;
    cout << "Enter the number of seconds that have\n";
    cout << "elapsed since some time in the past and\n";
    cout << "I will tell you how many minutes, hours,ln";
    cout << "days, months, and years have passed: ";
    cin >> seconds;
```

```
    minutes = seconds / 60;
    hours = minutes / 60;
    days = hours / 24;
    years = days / 365;
    months = years * 12;
    cout << setprecision(4) << fixed << showpoint << right;
    cout << "Minutes: " << setw(6) << minutes << endl;
    cout << "Hours: " << setw(6) << hours << endl;
    cout << "Days: " << setw(6) << days << endl;
    cout << "Months: " << setw(6) << months << endl;
    cout << "Years: " << setw(6) << years << endl;
    return 0;
}
```

## Programming Challenges

## 1. Gallons to Liters

Write a program that calculates the price of gasoline. The program should ask the user to input the volume of gasoline in liters. It should then display the volume in gallons and the corresponding price. Assume that the price of gasoline is $\$ 3.58$ per gallon. Note that 1 gallon $=4.546$ liters .

## 2. Stadium Seating

There are three seating categories at a stadium. For a softball game, Class A seats cost $\$ 15$, Class B seats cost $\$ 12$, and Class C seats cost $\$ 9$. Write a program that asks how many tickets for each class of seats were sold, then displays the amount of income generated from ticket sales. Format your dollar amount in fixed-point notation, with two decimal places of precision, and be sure the decimal point is always displayed.

## 3. Percentage of Scores

Write a program that asks for the test scores of six subjects. Each subject can have a maximum score of 100 . The program should calculate and display the total score and the percentage obtained out of 600 , formatted in fixed-point notation, with two decimal points of precision.

## 4. Average Rainfall

Write a program that calculates the average rainfall for three months. The program should ask the user to enter the name of each month, such as June or July, and the amount of rain (in inches) that fell each month. The program should display a message similar to the following:
The average rainfall for June, July, and August is 6.72 inches.

## 5. Battery Charge Consumption

Battery consumption is a major issue for portable electronics, especially smartphones. A full battery may contain 3000 mAh , but if a component requires 300 mA of current, after only 10 hours the battery will be completely drained.
Suppose that using GPS consumes 148 mA , WiFi uses 352 mA , and the display uses 197 mA at full brightness. Write a program that lets the user input the time spent using GPS, on WiFi with the display on full brightness, and calculates the battery consumption.

## 6. Surface Area and Volume of a Cylinder

The surface area A of a cylinder is given by the following formula:

$$
A=2 \pi r h+2 \pi r^{2}
$$

The volume V of a cylinder is given by the following formula:

$$
V=\pi r^{2} b
$$

The term r is the radius and h is the height of the cylinder. Write a program that asks the user for the radius and height of the cylinder and displays the area and volume. Assume that value of $\pi$ is 3.1415926535 .

## 7. Box Office

A movie theater only keeps a percentage of the revenue earned from ticket sales. The remainder goes to the movie distributor. Write a program that calculates a theater's gross and net box office profit for a night. The program should ask for the name of the movie, and how many adult and child tickets were sold. (The price of an adult ticket is $\$ 10.00$ and a child's ticket is $\$ 6.00$.) It should display a report similar to:

| Movie Name: | "Wheels of Fury" |
| :--- | :---: |
| Adult Tickets Sold: | 382 |
| Child Tickets Sold: | 127 |
| Gross Box Office Profit: | $\$ 4,582.00$ |
| Net Box Office Profit: | $\$ 916.40$ |
| Amount Paid to Distributor: | $\$ 3,665.60$ |

NOTE: Assume the theater keeps 20 percent of the gross box office profit.

## 8. How Many Widgets?

The Yukon Widget Company manufactures widgets that weigh 12.5 pounds each. Write a program that calculates how many widgets are stacked on a pallet, based on the total weight of the pallet. The program should ask the user how much the pallet weighs by itself and with the widgets stacked on it. It should then calculate and display the number of widgets stacked on the pallet.

## 9. How Many Calories?

A bag of cookies holds 30 cookies. The calorie information on the bag claims there are 10 "servings" in the bag and that a serving equals 300 calories. Write a program that asks the user to input how many cookies he or she actually ate, then reports how many total calories were consumed.

## 10. Guess the Number

Write a program that asks the user for two values and calculates a random number between the two values. Then print a message that informs the user that a number between the given inputs has been selected and ask the user to guess the actual number. Display the correct answer and the difference between the guess and the correct answer.

## 11. Automobile Costs

Write a program that asks the user to enter the monthly costs for the following expenses incurred from operating his or her automobile: loan payment, insurance, gas, oil, tires,
and maintenance. The program should then display the total monthly cost of these expenses, and the total annual cost of these expenses.

## 12. Sum of Two Fractions

The formula to find the sum of two fractions $\frac{a}{b}$ and $\frac{c}{d}$ is:
$\frac{a}{b}+\frac{c}{d}=\frac{a d+b c}{b d}$
Write a program that asks for the numerator and denominator of each fraction and displays the sum in fractional form.

## 13. Currency

Write a program that will convert U.S. dollar amounts to Japanese yen and to euros, storing the conversion factors in the constants YEN_PER_DOLLAR and EUROS_PER_ DOLLAR. To get the most up-to-date exchange rates, search the Internet using the term "currency exchange rate". If you cannot find the most recent exchange rates, use the following:

1 Dollar = 98.93 Yen
1 Dollar = 0.74 Euros
Format your currency amounts in fixed-point notation, with two decimal places of precision, and be sure the decimal point is always displayed.

## 14. Temperature in the Mountains

As one goes higher up the mountains, the temperature decreases. The rate at which this occurs is called the lapse rate. The actual value depends on the humidity of the air. We can easily use the typical value of around $5^{\circ} \mathrm{C} / \mathrm{km}$ or $2.7^{\circ} \mathrm{F} / 1000 \mathrm{ft}$.
Write a program that asks the user for the temperature at sea level in degrees Celsius and displays the following:

The temperature at sea level (for reference)
The temperature at 1000,2000 and 3000 m
The temperature at the top of Mount Everest ( 8.848 m )
The height at which the temperature is $0^{\circ} \mathrm{C}$
As an additional exercise, show also the temperatures in degrees Fahrenheit and the height in feet. To convert temperatures in degrees Celsius to degrees Fahrenheit, multiply by 1.8 (or $9 / 5$ ) and add 32 ; to convert meters to feet, multiply by 3.28 .

## 15. Container Space

Containers are used when shipping large amounts of goods between countries. The shipping cost depends on the number of containers, not on how much they are filled. The capacity of a container is typically expressed in liters. Write a program that asks for the capacity of a container in liters and the amount of goods to be shipped (also in liters). Display the number of containers needed and the amount of free space remaining.

## 16. Rectangular to Polar Coordinates

A point in a rectangular coordinate system is represented by $(x, y)$, where $x$ is its position along the $x$-axis and $y$ is its position along the $y$-axis. The point can be represented in a polar coordinate system by $(r, \theta)$, where $r$ is the distance of the point from the origin and $\theta$ is the angle in radians between the $x$-axis and the line joining the point with the origin. To convert from the rectangular to the polar coordinates, the following formulas are used:
$r^{2}=x^{2}+y^{2}$
$\theta=\tan ^{-1}(x / y)$
Write a program that asks the user for the position of a point in the rectangular coordinate system and displays the point in the polar coordinate system. (Use library function atan for finding $\theta$.)

## 17. Math Tutor

Write a program that can be used as a math tutor for a young student. The program should display two random numbers to be added, such as
$+129$
The program should then pause while the student works on the problem. When the student is ready to check the answer, he or she can press a key and the program will display the correct solution:

$$
247
$$

$\begin{array}{r}+129 \\ \hline 376\end{array}$

## 18. Interest Earned

Assuming there are no deposits other than the original investment, the balance in a savings account after one year may be calculated as

$$
\text { Amount }=\text { Principal } \times\left(1+\frac{\text { Rate }}{T}\right)^{\top}
$$

Principal is the balance in the savings account, Rate is the interest rate, and $T$ is the number of times the interest is compounded during a year ( T is 4 if the interest is compounded quarterly).
Write a program that asks for the principal, the interest rate, and the number of times the interest is compounded. It should display a report similar to:

| Interest Rate: |  | $4.25 \%$ |
| :--- | ---: | ---: |
| Times Compounded: |  | 12 |
| Principal: | $\$ 1000.00$ |  |
| Interest: | $\$$ | 43.34 |
| Amount in Savings: | $\$ 1043.34$ |  |

## 19. Monthly Payments

The monthly payment on a loan may be calculated by the following formula:

$$
\text { Payment }=\frac{\text { Rate } \times(1+\text { Rate })^{N}}{\left((1+\text { Rate })^{N}-1\right)} \times L
$$

Rate is the monthly interest rate, which is the annual interest rate divided by 12 . (12 percent annual interest would be 1 percent monthly interest.) N is the number of payments, and L is the amount of the loan. Write a program that asks for these values then displays a report similar to:
Loan Amount: \$ 10000.00
Monthly Interest Rate: 1\%
Number of Payments: 36
Monthly Payment: \$ 332.14
Amount Paid Back: \$ 11957.15
Interest Paid: \$ 1957.15

## 20. Pizza Pi

Joe's Pizza Palace needs a program to calculate the number of slices a pizza of any size can be divided into. The program should perform the following steps:
A) Ask the user for the diameter of the pizza in inches.
B) Calculate the number of slices that may be taken from a pizza of that size.
A) Display a message telling the number of slices.

To calculate the number of slices that may be taken from the pizza, you must know the following facts:

- Each slice should have an area of 14.125 inches.
- To calculate the number of slices, simply divide the area of the pizza by 14.125 .
- The area of the pizza is calculated with this formula:

$$
\text { Area }=\pi r^{2}
$$

NOTE: $\pi$ is the Greek letter pi. 3.14159 can be used as its value. The variable $r$ is the radius of the pizza. Divide the diameter by 2 to get the radius.

Make sure the output of the program displays the number of slices in fixed-point notation, rounded to one decimal place of precision. Use a named constant for pi.

## 21. How Many Pizzas?

Modify the program you wrote in Programming Challenge 20 (Pizza Pi) so it reports the number of pizzas you need to buy for a party if each person attending is expected to eat an average of four slices. The program should ask the user for the number of people who will be at the party, and for the diameter of the pizzas to be ordered. It should then calculate and display the number of pizzas to purchase.

## 22. Angle Calculator

Write a program that asks the user for an angle, entered in radians. The program should then display the sine, cosine, and tangent of the angle. (Use the sin, cos, and tan library functions to determine these values.) The output should be displayed in fixed-point notation, rounded to four decimal places of precision.

## 23. Stock Transaction Program

Last month Joe purchased some stock in Acme Software, Inc. Here are the details of the purchase:

- The number of shares that Joe purchased was 1,000 .
- When Joe purchased the stock, he paid $\$ 45.50$ per share.
- Joe paid his stockbroker a commission that amounted to 2 percent of the amount he paid for the stock.

Two weeks later, Joe sold the stock. Here are the details of the sale:

- The number of shares that Joe sold was 1,000 .
- He sold the stock for $\$ 56.90$ per share.
- He paid his stockbroker another commission that amounted to 2 percent of the amount he received for the stock.

Write a program that displays the following information:

- The amount of money Joe paid for the stock.
- The amount of commission Joe paid his broker when he bought the stock.
- The amount that Joe sold the stock for.
- The amount of commission Joe paid his broker when he sold the stock.
- Display the amount of profit that Joe made after selling his stock and paying the two commissions to his broker. (If the amount of profit that your program displays is a negative number, then Joe lost money on the transaction.)

## 24. Planting Grapevines

A vineyard owner is planting several new rows of grapevines, and needs to know how many grapevines to plant in each row. She has determined that after measuring the length of a future row, she can use the following formula to calculate the number of vines that will fit in the row, along with the trellis end-post assemblies that will need to be constructed at each end of the row:
$V=\frac{R-2 E}{S}$
The terms in the formula are:
$V$ is the number of grapevines that will fit in the row.
$R$ is the length of the row, in feet.
$E$ is the amount of space, in feet, used by an end-post assembly.
$S$ is the space between vines, in feet.
Write a program that makes the calculation for the vineyard owner. The program should ask the user to input the following:

- The length of the row, in feet
- The amount of space used by an end-post assembly, in feet
- The amount of space between the vines, in feet

Once the input data has been entered, the program should calculate and display the number of grapevines that will fit in the row.

## 25. Word Game

Write a program that plays a word game with the user. The program should ask the user to enter the following:

- His or her name
- His or her age
- The name of a city
- The name of a college
- A profession
- A type of animal
- A pet's name

After the user has entered these items, the program should display the following story, inserting the user's input into the appropriate locations:

There once was a person named NAME who lived in CITY. At the age of AGE, NAME went to college at COLLEGE. NAME graduated and went to work as a PROFESSION. Then, NAME adopted a(n) ANIMAL named PETNAME. They both lived happily ever after!

### 4.1 Relational Operators

CONCEPT: Relational operators allow you to compare numeric and char values and determine whether one is greater than, less than, equal to, or not equal to another.

So far, the programs you have written follow this simple scheme:

- Gather input from the user.
- Perform one or more calculations.
- Display the results on the screen.

Computers are good at performing calculations, but they are also quite adept at comparing values to determine whether one is greater than, less than, or equal to the other. These types of operations are valuable for tasks such as examining sales figures, determining profit and loss, checking a number to ensure it is within an acceptable range, and validating the input given by a user.

Numeric data is compared in C++ by using relational operators. Each relational operator determines whether a specific relationship exists between two values. For example,
the greater-than operator $(>)$ determines if a value is greater than another. The equality operator (==) determines if two values are equal. Table 4-1 lists all of C++'s relational operators.

## Table 4-1 Relational Operators

| Relational Operators | Meaning |
| :--- | :--- |
| $>$ | Greater than |
| $<$ | Less than |
| $>=$ | Greater than or equal to |
| $<=$ | Less than or equal to |
| $==$ | Equal to |
| $!=$ | Not equal to |

All of the relational operators are binary, which means they use two operands. Here is an example of an expression using the greater-than operator:

```
x > y
```

This expression is called a relational expression. It is used to determine whether x is greater than y . The following expression determines whether x is less than y :

$$
x<y
$$

Table 4-2 shows examples of several relational expressions that compare the variables x and $y$.

## Table 4-2 Relational Expressions

| Expression | What the Expression Means |
| :--- | :--- |
| $x>y$ | Is $x$ greater than $y ?$ |
| $x<y$ | Is $x$ less than $y ?$ |
| $x>=y$ | Is $x$ greater than or equal to $y$ ? |
| $x<=y$ | Is $x$ less than or equal to $y ?$ |
| $x==y$ | Is $x$ equal to $y$ ? |
| $x!=y$ | Is $x$ not equal to $y ?$ |

## NOTE: All the relational operators ha ciativity is the order in which an operato The Value of a Relationship

So, how are relational expressions used in a program? Remember, all expressions have a value. Relational expressions are also known as Boolean expressions, which means their value can only be true or false. If x is greater than y , the expression $\mathrm{x}>\mathrm{y}$ will be true, while the expression $\mathrm{y}==\mathrm{x}$ will be false.

The == operator determines whether the operand on its left is equal to the operand on its right. If both operands have the same value, the expression is true. Assuming that a is 4 , the following expression is true:

$$
a=4
$$

But the following is false:

$$
a=2
$$

WARNING! Notice the equality operator is two = symbols together. Don't confuse this operator with the assignment operator, which is one $=$ symbol. The $==$ operator determines whether a variable is equal to another value, but the = operator assigns the value on the operator's right to the variable on its left. There will be more about this later in the chapter.

A couple of the relational operators actually test for two relationships. The >= operator determines whether the operand on its left is greater than or equal to the operand on the right. Assuming a is $4, \mathrm{~b}$ is 6 , and c is 4 , both of the following expressions are true:

$$
\begin{aligned}
& b>=a \\
& a>=c
\end{aligned}
$$

But the following is false:
$a>=5$
The <= operator determines whether the operand on its left is less than or equal to the operand on its right. Once again, assuming $a$ is 4 , $b$ is 6 , and $c$ is 4 , both of the following expressions are true:

```
a <= c
b <= 10
```

But the following is false:

```
b <= a
```

The last relational operator is $!=$, which is the not-equal-to operator. It determines whether the operand on its left is not equal to the operand on its right, which is the opposite of the $==$ operator. As before, assuming a is $4, \mathrm{~b}$ is 6 , and c is 4 , both of the following expressions are true:

```
a != b
b != c
```

These expressions are true because a is not equal to b and b is not equal to c . But the following expression is false because a is equal to c :
a != c

Table 4-3 shows other relational expressions and their true or false values.

Table 4-3 (Assume x is 10 and y is 7. )

| Expression | Value |
| :--- | :--- |
| $x<y$ | False, because $x$ is not less than $y$. |
| $x>y$ | True, because $x$ is greater than $y$. |
| $x>=y$ | True, because $x$ is greater than or equal to $y$. |
| $x<=y$ | False, because $x$ is not less than or equal to $y$. |
| $y!=x$ | True, because $y$ is not equal to $x$. |

## What Is Truth?

The question "what is truth?" is one you would expect to find in a philosophy book, not a C++ programming text. It's a good question for us to consider, though. If a relational expression can be either true or false, how are those values represented internally in a program? How does a computer store true in memory? How does it store false?

As you saw in Program 2-17, those two abstract states are converted to numbers. In C++, relational expressions represent true states with the number 1 , and false states with the number 0 .

NOTE: As you will see later in this chapter, 1 is not the only value regarded as true.

To illustrate this more fully, look at Program 4-1.

## Program 4-1

```
// This program displays the values of true and false states.
#include <iostream>
using namespace std;
int main()
{
    bool trueValue, falseValue;
    int x = 5, y = 10;
    trueValue = x < y;
    falseValue = y == x;
    cout << "True is " << trueValue << endl;
    cout << "False is " << falseValue << endl;
    return 0;
}
```

## Program Output

True is 1
False is 0

Let's examine the statements containing the relational expressions, in lines 10 and 11, a little closer:

```
trueValue = x < y;
falseValue = y == x;
```

These statements may seem odd because they are assigning the value of a comparison to a variable. In line 10 , the variable trueValue is being assigned the result of $x<y$. Since $x$ is less than $y$, the expression is true, and the variable trueValue is assigned the value 1 . In line 11 , the expression $y==x$ is false, so the variable falseValue is set to 0 . Table $4-4$ shows examples of other statements using relational expressions and their outcomes.

NOTE: Relational expressions have a higher precedence than the assignment operator. In the statement
$z=x<y ;$
the expression $x<y$ is evaluated first, then its value is assigned to $z$.

Table 4-4 (Assume $x$ is 10, $y$ is 7, and $z$, $a$, and $b$ are ints or boo 1 s.)

| Statement | Outcome |
| :--- | :--- |
| $z=x<y$ | $z$ is assigned 0 because $x$ is not less than $y$. |
| cout $\ll(x>y) ;$ | Displays 1 because $x$ is greater than $y$. |
| $a=x>=y ;$ | a is assigned 1 because $x$ is greater than or equal to $y$. |
| cout $\ll(x<=y) ;$ | Displays 0 because $x$ is not less than or equal to $y$. |
| $b=y!=x ;$ | $b$ is assigned 1 because $y$ is not equal to $x$. |

When writing statements such as these, it sometimes helps to enclose the relational expression in parentheses, such as:

```
trueValue = (x < y);
falseValue = (y == x);
```

As interesting as relational expressions are, we've only scratched the surface of how to use them. In this chapter's remaining sections, you will see how to get the most from relational expressions by using them in statements that take action based on the results of the comparison.

## Checkpoint

4.1 Assuming $x$ is 5 , $y$ is 6 , and $z$ is 8 , indicate whether each of the following relational expressions is true or false:
A) $x=5$
B) $7<=(x+2)$
C) $z<4$
D) $(2+x) \quad!=y$
E) $z \quad!=4$
F) $x>=9$
G) $x<=(y$ * 2$)$
4.2 Indicate whether the following statements about relational expressions are correct or incorrect:
A) $x<=y$ is the same as $y>x$.
B) $x \quad!=y$ is the same as $y>=x$.
C) $x>=y$ is the same as $y<=x$.
4.3 Answer the following questions with a yes or no:
A) If it is true that $x>y$ and it is also true that $x<z$, does that mean $y<z$ is true?
B) If it is true that $x>=y$ and it is also true that $z==x$, does that mean that $z==y$ is true?
C) If it is true that $x!=y$ and it is also true that $x!=z$, does that mean that $z \quad!=y$ is true?
4.4 What will the following program display?

```
#include <iostream>
using namespace std;
int main ()
{
        int a = 0, b = 2, x = 4, y = 0;
        cout << (a == b) << endl;
        cout << (a != y) << endl;
        cout << (b <= x) << endl;
        cout << (y > a) << endl;
        return 0;
}
```

### 4.2 The if Statement

CONCEPT: The if statement can cause other statements to execute only under certain conditions.

You might think of the statements in a procedural program as individual steps taken as you are walking down a road. To reach the destination, you must start at the beginning and take each step, one after the other, until you reach the destination. The programs you have written so far are like a "path" of execution for the program to follow.

The type of code in Figure 4-1 is called a sequence structure because the statements are executed in sequence, without branching off in another direction. Programs often need more than one path of execution, however. Many algorithms require a program to execute some statements only under certain circumstances. This can be accomplished with a decision structure.

In a decision structure's simplest form, a specific action is taken only when a specific condition exists. If the condition does not exist, the action is not performed. The flowchart in Figure 4-2 shows the logic of a decision structure. The diamond symbol represents a yes/no

Figure 4-1 Sequence structure

question or a true/false condition. If the answer to the question is yes (or if the condition is true), the program flow follows one path, which leads to an action being performed. If the answer to the question is no (or the condition is false), the program flow follows another path, which skips the action.

Figure 4-2 Decision structure

In the flowchart, the action "Wear a coat" is performed only when it is cold outside. If it is not cold outside, the action is skipped. The action is conditionally executed because it is performed only when a certain condition (cold outside) exists. Figure 4-3 shows a more elaborate flowchart, where three actions are taken only when it is cold outside.

We perform mental tests like these every day. Here are some other examples:
If the car is low on gas, stop at a service station and get gas.
If it's raining outside, go inside.
If you're hungry, get something to eat.

One way to code a decision structure in C++ is with the if statement. Here is the general format of the if statement:

```
if (expression)
    statement;
```

The if statement is simple in the way it works: If the value of the expression inside the parentheses is true, the very next statement is executed. Otherwise, it is skipped. The statement is conditionally executed because it only executes under the condition that the expression in the parentheses is true. Program 4-2 shows an example of an if statement. The user enters three test scores, and the program calculates their average. If the average is greater than 95 , the program congratulates the user on obtaining a high score.

## Program 4-2

```
// This program averages three test scores
#include <iostream>
#include <iomanip>
using namespace std;
int main()
{
    const int HIGH_SCORE = 95; // A high score is 95 or greater
    int score1, score2, score3; /l To hold three test scores
    double average; // To hold the average score
```

```
    // Get the three test scores.
    cout << "Enter 3 test scores and I will average them: ";
    cin >> score1 >> score2 >> score3;
    // Calculate and display the average score.
    average = (score1 + score2 + score3) / 3.0;
    cout << fixed << showpoint << setprecision(1);
    cout << "Your average is " << average << endl;
    // If the average is a high score, congratulate the user.
    if (average > HIGH_SCORE)
        cout << "Congratulations! That's a high score!\n";
    return 0;
}
```

## Program Output with Example Input Shown in Bold

Enter 3 test scores and I will average them: $\mathbf{8 0 9 0 7 0} \mathbf{7 0}$ Enter
Your average is 80.0

## Program Output with Different Example Input Shown in Bold

Enter 3 test scores and I will average them: $\mathbf{1 0 0 1 0 0 1 0 0}$ Enter
Your average is 100.0
Congratulations! That's a high score!

Lines 22 and 23 cause the congratulatory message to be printed:

```
if (average > HIGH_SCORE)
    cout << "Congratulations! That's a high score!\n";
```

The cout statement in line 23 is executed only if the average is greater than 95 , the value of the HIGH_SCORE constant. If the average is not greater than 95, the cout statement is skipped. Figure $4-4$ shows the logic of this if statement.

Figure 4-4 if statement logic

Table 4-5 shows other examples of if statements and their outcomes.

Table 4-5 if Statements and Their Outcomes

| Statement | Outcome |
| :--- | :--- |
| if (hours > 40) | Assigns true to the bool variable overTime only |
| $\quad$ overTime $=$ true; | if hours is greater than 40 |
| if (value > 32) | Displays the message "Invalid number" only if |
| $\quad$ cout << "Invalid number $\backslash n " ;$ | value is greater than 32 |
| if (overTime == true) | Multiplies payRate by 2 only if overTime is equal <br> payRate * $=2 ;$ |

## Be Careful with Semicolons

Semicolons do not mark the end of a line, but the end of a complete C++ statement. The if statement isn't complete without the conditionally executed statement that comes after it. So, you must not put a semicolon after the if (expression) portion of an if statement.

No semicolon goes here.

If you inadvertently put a semicolon after the if part, the compiler will assume you are placing a null statement there. The null statement is an empty statement that does nothing. This will prematurely terminate the if statement, which disconnects it from the statement that follows it. The statement following the if will always execute, as shown in Program 4-3.

## Program 4-3

```
// This program demonstrates how a misplaced semicolon
// prematurely terminates an if statement.
#include <iostream>
using namespace std;
int main()
{
    int x = 0, y = 10;
    cout << "x is " << x << " and y is " << y << endl;
    if (x > y); // Error! Misplaced semicolon
            cout << "x is greater than y\n"; //This is always executed.
        return 0;
}
```

## Program Output

```
x is 0 and y is 10
x is greater than y
```

## Programming Style and the if Statement

Even though if statements usually span more than one line, they are technically one long statement. For instance, the following if statements are identical except in style:

```
if (a >= 100)
    cout << "The number is out of range.\n";
if (a >= 100) cout << "The number is out of range.\n";
```

In both the examples above, the compiler considers the if part and the cout statement as one unit, with a semicolon properly placed at the end. Indention and spacing are for the human readers of a program, not the compiler. Here are two important style rules you should adopt for writing if statements:

- The conditionally executed statement should appear on the line after the if statement.
- The conditionally executed statement should be indented one "level" from the if statement.

NOTE: In most editors, each time you press the tab key, you are indenting one level.

By indenting the conditionally executed statement, you are causing it to stand out visually. This is so that you can tell at a glance what part of the program the if statement executes. This is a standard way of writing if statements, and is the method you should use.

NOTE: Indentation and spacing are for the human readers of a program, not the compiler. Even though the cout statement following the if statement in Program 4-3 is indented, the semicolon still terminates the if statement.

## Comparing Floating-Point Numbers

Because of the way floating-point numbers are stored in memory, rounding errors sometimes occur. This is because some fractional numbers cannot be exactly represented using binary. So, you should be careful when using the equality operator ( $==$ ) to compare floating-point numbers. For example, Program 4-4 uses two double variables, a and b. Both variables are initialized to the value 1.5 . Then, the value 0.0000000000000001 is added to a. This should make a's contents different from b's contents. Because of a roundoff error, however, the two variables are still the same.

## Program 4-4

```
// This program demonstrates how floating-point
// round-off errors can make equality operations unreliable.
#include <iostream>
using namespace std;
int main()
{
```

## Program 4-4

(continued)

```
    double a = 1.5; // a is 1.5.
    double b = 1.5; // b is 1.5.
    a += 0.0000000000000001; // Add a little to a.
    if (a == b)
    cout << "Both a and b are the same.\n";
    else
    cout << "a and b are not the same.\n";
return 0;
}
```

## Program Output

Both $a$ and $b$ are the same.

To prevent round-off errors from causing this type of problem, you should stick with greater-than and less-than comparisons with floating-point numbers.

## And Now Back to Truth

Now that you've gotten your feet wet with relational expressions and if statements, let's look at the subject of truth again. You have seen that a relational expression has the value 1 when it is true and 0 when false. In the world of the if statement, however, the concept of truth is expanded. 0 is still false, but all values other than 0 are considered true. This means that any value, even a negative number, represents as true as long as it is not 0 .

Just as in real life, truth is a complicated thing. Here is a summary of the rules you have seen so far:

- When a relational expression is true, it has the value 1.
- When a relational expression is false, it has the value 0 .
- Any expression that has the value 0 is considered false by the if statement. This includes the bool value false, which is equivalent to 0 .
- Any expression that has any value other than 0 is considered true by the if statement. This includes the bool value true, which is equivalent to 1 .

The fact that the if statement considers any nonzero value as true opens many possibilities. Relational expressions are not the only conditions that may be tested. For example, the following is a legal if statement in C++:

```
if (value)
```

    cout << "It is True!";
    The if statement above does not test a relational expression, but rather the contents of a variable. If the variable, value, contains any number other than 0 , the message "It is True!" will be displayed. If value is set to 0 , however, the cout statement will be skipped. Here is another example:

```
if (x + y)
    cout << "It is True!";
```

In this statement, the sum of $x$ and $y$ is tested like any other value in an if statement: 0 is false and all other values are true. You may also use the return value of function calls as conditional expressions. Here is an example that uses the pow function:

```
if (pow(a, b))
    cout << "It is True!";
```

This if statement uses the pow function to raise a to the power of $b$. If the result is anything other than 0 , the cout statement is executed. This is a powerful programming technique that you will learn more about in Chapter 6.

## Don't Confuse == with =

Earlier you saw a warning not to confuse the equality operator (==) with the assignment operator ( $=$ ), as in the following statement:

```
if (x = 2) //Caution here!
    cout << "It is True!";
```

The statement above does not determine whether x is equal to 2 , it assigns x the value 2 ! Furthermore, the cout statement will always be executed because the expression $x=2$ is always true.

This occurs because the value of an assignment expression is the value being assigned to the variable on the left side of the $=$ operator. That means the value of the expression $\mathrm{x}=2$ is 2. Since 2 is a nonzero value, it is interpreted as a true condition by the if statement. Program 4-5 is a version of Program 4-2 that attempts to test for a perfect average of 100 . The = operator, however, was mistakenly used in the if statement.

## Program 4-5

```
// This program averages 3 test scores. The if statement
// uses the = operator, but the == operator was intended
#include <iostream>
#include <iomanip>
using namespace std;
int main()
{
    int score1, score2, score3; // To hold three test scores
    double average; // To hold the average score
    // Get the three test scores
    cout << "Enter 3 test scores and I wil1 average them: ";
    cin >> score1 >> score2 >> score3;
    // Calculate and display the average score.
    average = (score1 + score2 + score3) / 3.0;
    cout << fixed << showpoint << setprecision(1);
    cout << "Your average is " << average << endl;
```

```
Program 4-5 (continued)
    // Our intention is to congratulate the user
    // for having a perfect score. But, this doesn't work.
    if (average = 100) // WRONG! This is an assignment!
    cout << "Congratulations! That's a perfect score!\n";
    return 0;
    }
```

## Program Output with Example Input Shown in Bold

Enter three test scores and I will average them: $\mathbf{8 0 9 0 7 0} \mathbf{7 0}$ Enter
Your average is 80.0
Congratulations! That's a perfect score!

Regardless of the average score, this program will print the message congratulating the user on a perfect score.

Checkpoint
4.5 Write an if statement that performs the following logic: if the variable x is equal to 20 , then assign 0 to the variable $y$.
4.6 Write an if statement that performs the following logic: if the variable price is greater than 500 , then assign 0.2 to the variable discountRate.
4.7 Write an if statement that multiplies payRate by 1.5 if hours is greater than 40.
4.8 True or False: Both of the following if statements perform the same operation.

```
if (sales > 10000)
    commissionRate = 0.15;
    if (sales > 10000) commissionRate = 0.15;
```

4.9 True or false: Both of the following if statements perform the same operation.
if (calls == 20)
rate *= 0.5;
if (calls = 20)
rate *= 0.5;

### 4.3 Expanding the if Statement

CONCEPT: The if statement can conditionally execute a block of statements enclosed in braces.

What if you want an if statement to conditionally execute a group of statements, not just one line? For instance, what if the test-averaging program needed to use several cout
statements when a high score was reached? The answer is to enclose all of the conditionally executed statements inside a set of braces. Here is the format:

```
if (expression)
{
    statement;
    statement;
    // Place as many statements here as necessary.
}
```

Program 4-6, another modification of the test-averaging program, demonstrates this type of if statement.

## Program 4-6

```
// This program averages 3 test scores.
// It demonstrates an if statement executing
// a block of statements.
#include <iostream>
#include <iomanip>
using namespace std;
int main()
{
    const int HIGH_SCORE = 95; // A high score is 95 or greater
    int score1, score2, score3; // To hold three test scores
    double average; // To hold the average score
    // Get the three test scores.
    cout << "Enter 3 test scores and I will average them: ";
    cin >> score1 >> score2 >> score3;
    // Calculate and display the average score.
    average = (score1 + score2 + score3) / 3.0;
    cout << fixed << showpoint << setprecision(1);
    cout << "Your average is " << average << endl;
    // If the average is high, congratulate the user.
    if (average > HIGH_SCORE)
    {
        cout << "Congratulations!\n";
        cout << "That's a high score.\n";
        cout << "You deserve a pat on the back!\n";
    }
        return 0;
}
```

```
Program 4-6
(continued)
```

```
Program Output with Example Input Shown in Bold
```

Program Output with Example Input Shown in Bold
Enter 3 test scores and I will average them: 100 100 100 Enter
Enter 3 test scores and I will average them: 100 100 100 Enter
Your average is 100.0
Your average is 100.0
Congratulations!
Congratulations!
That's a high score.
That's a high score.
You deserve a pat on the back!

```
You deserve a pat on the back!
```

Program Output with Different Example Input Shown in Bold
Enter 3 test scores and I will average them: $\mathbf{8 0 9 0 7 0} \mathbf{9 0}$ Enter
Your average is 80.0

Program 4-6 prints a more elaborate message when the average score is greater than 95 . The if statement was expanded to execute three cout statements when highScore is set to true. Enclosing a group of statements inside a set of braces creates a block of code. The if statement will execute all the statements in the block, in the order they appear, only when average is greater than 95 . Otherwise, the block will be skipped.

Notice all the statements inside the braces are indented. As before, this visually separates the statements from lines that are not indented, making it more obvious they are part of the if statement.

NOTE: Anytime your program has a block of code, all the statements inside the braces should be indented.

## Don't Forget the Braces!

If you intend to conditionally execute a block of statements with an if statement, don't forget the braces. Remember, without a set of braces, the if statement only executes the very next statement. Program 4-7 shows the test-averaging program with the braces inadvertently left out of the if statement's block.

## Program 4-7

```
// This program averages 3 test scores. The braces
// were inadvertently left out of the if statement.
#include <iostream>
#include <iomanip>
using namespace std;
    int main()
{
    const int HIGH_SCORE = 95; // A high score is 95 or greater
    int score1, score2, score3; // To hold three test scores
    double average; // To hold the average score
```

```
1 3
14
1 5
16
1 7
1 8
19
20
21
22
23
24
25
26
27
28
```

## Program Output with Example Input Shown in Bold

Enter 3 test scores and I will average them: $\mathbf{8 0 9 0 7 0} \mathbf{7 0}$ Enter
Your average is 80
That's a high score.
You deserve a pat on the back!

The cout statements in lines 25 and 26 are always executed, even when average is not greater than 95 . Because the braces have been removed, the if statement only controls execution of line 24. This is illustrated in Figure 4-5.

Figure 4-5 Conditionally executed statement

## Checkpoint

4.10 Write an if statement that performs the following logic: if the variable sales is greater than 50,000 , then assign 0.25 to the commissionRate variable, and assign 250 to the bonus variable.
4.11 The following code segment is syntactically correct, but it appears to contain a logic error. Can you find the error?

```
if (interestRate > .07)
cout << "This account earns a $10 bonus.\n";
balance += 10.0;
```

### 4.4 The if/else Statement

CONCEPT: The if/else statement will execute one group of statements if the expression is true, or another group of statements if the expression is false.

```
if (expression)
    statement or block
e1se
    statement or block
```

As with the if statement, an expression is evaluated. If the expression is true, a statement or block of statements is executed. If the expression is false, however, a separate group of statements is executed. Program 4-8 uses the if/else statement along with the modulus operator to determine if a number is odd or even.

## Program 4-8

```
// This program uses the modulus operator to determine
// if a number is odd or even. If the number is evenly divisible
// by 2, it is an even number. A remainder indicates it is odd.
#include <iostream>
using namespace std;
int main()
{
    int number;
    cout << "Enter an integer and I will tell you if it\n";
    cout << "is odd or even. ";
    cin >> number;
    if (number % 2 == 0)
        cout << number << " is even.\n";
    else
        cout << number << " is odd.\n";
    return 0;
}
```

## Program Output with Example Input Shown in Bold

```
Enter an integer and I will tell you if it
is odd or even. 17 Enter
17 is odd.
```

The else part at the end of the if statement specifies a statement that is to be executed when the expression is false. When number $\% 2$ does not equal 0 , a message is printed indicating the number is odd. Note the program will only take one of the two paths in the if/else statement. If you think of the statements in a computer program as steps taken down a road,
consider the $\mathrm{if} / \mathrm{el}$ se statement as a fork in the road. Instead of being a momentary detour, like an if statement, the if/else statement causes program execution to follow one of two exclusive paths. The flowchart in Figure 4-6 shows the logic of this if/el se statement.

Figure 4-6 $\mathrm{if} / \mathrm{e} 7$ se statement logic

Notice the programming style used to construct the $\mathrm{if} / \mathrm{el}$ se statement. The word else is at the same level of indention as if. The statement whose execution is controlled by else is indented one level. This visually depicts the two paths of execution that may be followed.
Like the if part, the else part controls a single statement. If you wish to control more than one statement with the else part, create a block by writing the lines inside a set of braces. Program 4-9 shows this as a way of handling a classic programming problem: division by zero.

Division by zero is mathematically impossible to perform, and it normally causes a program to crash. This means the program will prematurely stop running, sometimes with an error message. Program 4-9 shows a way to test the value of a divisor before the division takes place.

## Program 4-9

```
// This program asks the user for two numbers, num1 and num2.
// num1 is divided by num2 and the result is displayed.
// Before the division operation, however, num2 is tested
// for the value 0. If it contains 0, the division does not
// take place.
#include <iostream>
using namespace std;
int main()
{
    double num1, num2, quotient;
        // Get the first number.
        cout << "Enter a number: ";
        cin >> num1;
        // Get the second number.
        cout << "Enter another number: ";
        cin >> num2;
```

```
Program 4-9
(continued)
20
    // If num2 is not zero, perform the division.
    if (num2 == 0)
    {
        cout << "Division by zero is not possible.\n";
        cout << "Please run the program again and enter\n";
        cout << "a number other than zero.\n";
    }
    else
    {
        quotient = num1 / num2;
        cout << "The quotient of " << num1 << " divided by ";
        cout << num2 << " is " << quotient << ".\n";
        }
        return 0;
}
```

## Program Output with Example Input Shown in Bold

```
Enter a number: 10 Enter
Enter another number: 0 Enter
Division by zero is not possible.
Please run the program again and enter
a number other than zero.
```

The value of num 2 is tested in line 22 before the division is performed. If the user enters 0 , the lines controlled by the if part execute, displaying a message that indicates that the program cannot perform a division by zero. Otherwise, the el se part takes control, which divides num 1 by num 2 and displays the result.

## Checkpoint

4.12 True or false: The following if/else statements cause the same output to display.

```
A) if (x > y)
    cout << "x is the greater.\n";
    else
        cout << "x is not the greater.\n";
B) if (y <= x)
    cout << "x is not the greater.\n";
    else
    cout << "x is the greater.\n";
```

4.13 Write an $i f / e 1$ se statement that assigns 1 to $x$ if $y$ is equal to 100 . Otherwise, it should assign 0 to $x$.
4.14 Write an $\mathrm{if} / \mathrm{el}$ se statement that assigns 0.10 to commissionRate unless sales is greater than or equal to 50000.00 , in which case it assigns 0.20 to commissionRate.

### 4.5 Nested if Statements

CONCEPT: To test more than one condition, an if statement can be nested inside another if statement.

Sometimes an if statement must be nested inside another if statement. For example, consider a banking program that determines whether a bank customer qualifies for a special, low interest rate on a loan. To qualify, two conditions must exist: (1) the customer must be currently employed, and (2) the customer must have recently graduated from college (in the past 2 years). Figure $4-7$ shows a flowchart for an algorithm that could be used in such a program.

Figure 4-7 Nested decision structures

If we follow the flow of execution in the flowchart, we see that the expression employed $==$ ' $Y$ ' is tested. If this expression is false, there is no need to perform further tests; we know that the customer does not qualify for the special interest rate. If the expression is true, however, we need to test the second condition. This is done with a nested decision structure that tests the expression recentGrad $==$ ' $Y$ '. If this expression is true, then the customer qualifies for the special interest rate. If this expression is false, then the customer does not qualify. Program 4-10 shows the code for the complete program.

## Program 4-10

```
// This program demonstrates the nested if statement.
#include <iostream>
using namespace std;
int main()
{
    char employed, // Currently employed, Y or N
            recentGrad; // Recent graduate, Y or N
    // Is the user employed and a recent graduate?
    cout << "Answer the following questions\n";
    cout << "with either Y for Yes or ";
    cout << "N for No.\n";
    cout << "Are you employed? ";
    cin >> employed;
    cout << "Have you graduated from college ";
    cout << "in the past two years? ";
    cin >> recentGrad;
    // Determine the user's loan qualifications.
    if (employed == 'Y')
    {
        if (recentGrad == 'Y') //Nested if
        {
            cout << "You qualify for the special ";
            cout << "interest rate.\n";
        }
    }
    return 0;
}
```

## Program Output with Example Input Shown in Bold

Answer the following questions
with either $Y$ for Yes or $N$ for No.
Are you employed? Y Enter
Have you graduated from college in the past two years? Y Enter
You qualify for the special interest rate.

## Program Output with Different Example Input Shown in Bold

Answer the following questions
with either $Y$ for Yes or $N$ for No.
Are you employed? Y Enter
Have you graduated from college in the past two years? N Enter
Look at the if statement that begins in line 21. It tests the expression employed $==$ ' $Y$ '. If this expression is true, the if statement that begins in line 23 is executed. Otherwise, the program jumps to the return statement in line 29 and the program ends.

Notice in the second sample execution of Program 4-10 that the program output does not inform the user whether he or she qualifies for the special interest rate. If the user enters an ' N ' (or any character other than ' Y ') for employed or recentGrad, the program does not
print a message letting the user know that he or she does not qualify. An else statement should be able to remedy this, as illustrated by Program 4-11.

## Program 4-11

```
// This program demonstrates the nested if statement
#include <iostream>
using namespace std;
int main()
{
    char employed, // Currently employed, Y or N
        recentGrad; // Recent graduate, Y or N
    // Is the user employed and a recent graduate?
    cout << "Answer the following questions\n";
    cout << "with either Y for Yes or ";
    cout << "N for No.\n";
    cout << "Are you employed? ";
    cin >> employed;
    cout << "Have you graduated from college ";
    cout << "in the past two years? ";
    cin >> recentGrad;
    // Determine the user's loan qualifications.
    if (employed == 'Y')
    {
        if (recentGrad == 'Y') // Nested if
        {
            cout << "You qualify for the special ";
            cout << "interest rate.\n";
        }
        else // Not a recent grad, but employed
        {
            cout << "You must have graduated from ";
            cout << "college in the past two\n";
            cout << "years to qualify.\n";
        }
    }
    else // Not employed
    {
        cout << "You must be employed to qualify.\n";
    }
        return 0;
}
```

## Program Output with Example Input Shown in Bold

Answer the following questions
with either $Y$ for Yes or $N$ for No.
Are you employed? N Enter
Have you graduated from college in the past two years? $\mathbf{Y}$ Enter
You must be employed to qualify.

## Program 4-11 <br> (continued)

## Program Output with Different Example Input Shown in Bold

Answer the following questions
with either $Y$ for Yes or $N$ for No.
Are you employed? Y Enter
Have you graduated from college in the past two years? N Enter
You must have graduated from college in the past two years to qualify.

## Program Output with Different Example Input Shown in Bold

Answer the following questions
with either $Y$ for $Y$ es or $N$ for No.
Are you employed? $\mathbf{Y}$ Enter
Have you graduated from college in the past two years? Yenter You qualify for the special interest rate.

In this version of the program, both if statements have else clauses that inform the user why he or she does not qualify for the special interest rate.

## Programming Style and Nested Decision Structures

For readability and easier debugging, it's important to use proper alignment and indentation in a set of nested if statements. This makes it easier to see which actions are performed by each part of the decision structure. For example, the following code is functionally equivalent to lines 21 through 38 in Program 4-11. Although this code is logically correct, it is very difficult to read, and would be very difficult to debug because it is not properly indented.

```
if (employed == 'Y')
{
if (recentGrad == 'Y') // Nested if
{
cout << "You qualify for the special ";
cout << "interest rate.\n";
}
else // Not a recent grad, but employed
{
cout << "You must have graduated from ";
cout << "college in the past two\n";
cout << "years to qualify.\n";
}
}
else // Not employed
{
cout << "You must be employed to qualify.\n";
}
``` like this!

Proper indentation and alignment also makes it easier to see which if and else clauses belong together, as shown in Figure 4-8.

Figure 4-8 Proper indentation and alignment

\section*{Testing a Series of Conditions}

In the previous example, you saw how a program can use nested decision structures to test more than one condition. It is not uncommon for a program to have a series of conditions to test then perform an action depending on which condition is true. One way to accomplish this is to have a decision structure with numerous other decision structures nested inside it. For example, consider the program presented in the following In the Spotlight section.

\section*{In the Spotlight:}

\section*{Multiple Nested Decision Structures}

Dr. Suarez teaches a literature class and uses the following 10-point grading scale for all of his exams:
\begin{tabular}{ll} 
Test Score & Grade \\
\hline 90 and above & A \\
\(80-89\) & B \\
\(70-79\) & C \\
\(60-69\) & D \\
Below 60 & F
\end{tabular}

He has asked you to write a program that will allow a student to enter a test score and then display the grade for that score. Here is the algorithm that you will use:

Ask the user to enter a test score.
Determine the grade in the following manner:
If the score is greater than or equal to 90 , then the grade is \(A\).
Otherwise, if the score is greater than or equal to 80 , then the grade is \(B\).
Otherwise, if the score is greater than or equal to 70, then the grade is \(C\).
Otherwise, if the score is greater than or equal to 60 , then the grade is \(D\).
Otherwise, the grade is \(F\).

You decide that the process of determining the grade will require several nested decision structures, as shown in Figure 4-9. Program 4-12 shows the code for the complete program. The code for the nested decision structures is in lines 17 through 45.

Figure 4-9 Nested decision structure to determine a grade

\section*{Program 4-12}
```

// This program uses nested if/else statements to assign a
// letter grade (A, B, C, D, or F) to a numeric test score.
\#include <iostream>
using namespace std;
int main()
{
// Constants for grade thresholds
const int A_SCORE = 90,
B_SCORE = 80,
C_SCORE = 70,
D_SCORE = 60;
int testScore; // To hold a numeric test score
// Get the numeric test score.
cout << "Enter your numeric test score and I will\n";

```
```

cout << "tell you the letter grade you earned: ";
cin >> testScore;
// Determine the letter grade.
if (testScore >= A_SCORE)
{
cout << "Your grade is A.\n";
}
else
{
if (testScore >= B_SCORE)
{
cout << "Your grade is B.\n";
}
else
{
if (testScore >= C_SCORE)
{
cout << "Your grade is C.\n";
}
else
{
if (testScore >= D_SCORE)
{
cout << "Your grade is D.\n";
}
else
{
cout << "Your grade is F.ln";
}
}
}
}
return 0;
}

```

\section*{Program Output with Example Input Shown in Bold}

Enter your numeric test score and I will tell you the letter grade you earned: 78 Enter
Your grade is C.

\section*{Program Output with Different Example Input Shown in Bold}

Enter your numeric test score and I will
tell you the letter grade you earned: 84 Enter
Your grade is B.

\section*{Checkpoint}
4.15 If you executed the following code, what would it display if the user enters 5? What if the user enters 15 ? What if the user enters 30 ? What if the user enters -1 ?
```

int number;
cout << "Enter a number: ";
cin >> number;
if (number > 0)
{
cout << "Zero\n";
if (number > 10)
{
cout << "Ten\n";
if (number > 20)
{
cout << "Twenty\n";
}
}
}

```

\subsection*{4.6 The if/e1se if Statement}

CONCEPT: The if/else if statement tests a series of conditions. It is often simpler to test a series of conditions with the if/else if statement than with a set of nested \(\mathrm{if} / \mathrm{el}\) se statements.

VideoNote
The if/else if Statement

Even though Program 4-12 is a simple example, the logic of the nested decision structure is fairly complex. In C++, and many other languages, you can alternatively test a series of conditions using the if/else if statement. The if/else if statement makes certain types of nested decision logic simpler to write. Here is the general format of the \(\mathrm{if} / \mathrm{else}\) if statement:
```

```
if (expression_1)
```

```
if (expression_1)
{
{
    statement
    statement
    statement
    statement
    etc.
    etc.
}
}
e1se if (expression_2)
e1se if (expression_2)
{
{
    statement Otherwise, if expression_2 is true these
    statement Otherwise, if expression_2 is true these
    statement
    statement
    etc.
    etc.
}
}
Insert as many else if clauses as necessary
Insert as many else if clauses as necessary
else
else
{
{
    statement
    statement
    statement
    statement
    etc.
    etc.
}
```

```
}
```

```

If expression_1 is true these statements are executed, and the rest of the structure is ignored.

Otherwise, if expression_2 is true these statements are executed, and the rest of the structure is ignored.

When the statement executes, expression_1 is tested. If expression_1 is true, the block of statements that immediately follows is executed, and the rest of the structure is ignored. If expression_1 is false, however, the program jumps to the very next else if clause and tests expression_2. If it is true, the block of statements that immediately follows is executed, and then the rest of the structure is ignored. This process continues, from the top of the structure to the bottom, until one of the expressions is found to be true. If none of the expressions are true, the last e1 se clause takes over, and the block of statements immediately following it is executed.

The last e1se clause, which does not have an if statement following it, is referred to as the trailing else. The trailing e1se is optional, but in most cases you will use it.

NOTE: The general format shows braces surrounding each block of conditionally executed statements. As with other forms of the if statement, the braces are required only when more than one statement is conditionally executed.

Program 4-13 shows an example of the if/else if statement. This program is a modification of Program 4-12, which appears in the previous In the Spotlight section.

\section*{Program 4-13}
```

// This program uses an if/else if statement to assign a
// letter grade (A, B, C, D, or F) to a numeric test score.
\#include <iostream>
using namespace std;
int main()
{
// Constants for grade thresholds
const int A_SCORE = 90,
B_SCORE = 80,
C_SCORE = 70,
D_SCORE = 60;
int testScore; // To hold a numeric test score
// Get the numeric test score.
cout << "Enter your numeric test score and I will\n"
<< "tell you the letter grade you earned: ";
cin >> testScore;
// Determine the letter grade.
if (testScore >= A_SCORE)
cout << "Your grade is A.\n";
else if (testScore >= B_SCORE)
cout << "Your grade is B.\n";
else if (testScore >= C_SCORE)
cout << "Your grade is C.\n";
else if (testScore >= D_SCORE)
cout << "Your grade is D.\n";
e1se
cout << "Your grade is F.\n";

```
```

Program 4-13 (continued)
33 return 0;
34 }

```

\section*{Program Output with Example Input Shown in Bold}

Enter your numeric test score and I will tell you the letter grade you earned: 78 Enter
Your grade is C.

\section*{Program Output with Different Example Input Shown in Bold}
```

Enter your numeric test score and I will
tell you the letter grade you earned: 84 Enter
Your grade is B.

```

Let's analyze how the if/e1se if statement in lines 22 through 31 works. First, the expression testScore >= A_SCORE is tested in line 22:
```

if (testScore >= A_SCORE)
cout << "Your grade is A.ln";
else if (testScore >= B_SCORE)
cout << "Your grade is B.\n";
else if (testScore >= C_SCORE)
cout << "Your grade is C.\n";
else if (testScore >= D_SCORE)
cout << "Your grade is D.\n";
else
cout << "Your grade is F.\n";

```

If testScore is greater than or equal to 90 , the string "Your grade is A. \(\ln\) " is displayed and the rest of the \(\mathrm{if} / \mathrm{else} \mathrm{if}\) statement is skipped. If testScore is not greater than or equal to 90 , the e1 se clause in line 24 takes over and causes the next if statement to be executed:
```

    if (testScore >= A_SCORE)
    cout << "Your grade is A.\n";
    -> else if (testScore >= B_SCORE)
cout << "Your grade is B.ln";
else if (testScore >= C_SCORE)
cout << "Your grade is C.\n";
else if (testScore >= D_SCORE)
cout << "Your grade is D.\n";
else
cout << "Your grade is F.\n";

```

The first if statement handles all of the grades greater than or equal to 90 , so when this if statement executes, testScore will have a value of 89 or less. If testScore is greater than or equal to 80 , the string "Your grade is B. \(\backslash \mathrm{n}\) " is displayed and the rest of the \(\mathrm{if} /\) else if statement is skipped. This chain of events continues until one of the expressions is found to be true, or the last else clause at the end of the statement is encountered.

Notice the alignment and indentation that is used with the if/else if statement: The starting if clause, the e1se if clauses, and the trailing else clause are all aligned, and the conditionally executed statements are indented.

\section*{Using the Trailing e1se to Catch Errors}

The trailing e1 se clause, which appears at the end of the if/else if statement, is optional, but in many situations you will use it to catch errors. For example, Program 4-13 will assign a grade to any number that is entered as the test score, including negative numbers. If a negative test score is entered, however, the user has probably made a mistake. We can modify the code as shown in Program 4-14 so the trailing e1 se clause catches any test score that is less than 0 and displays an error message.

\section*{Program 4-14}
```

// This program uses an if/else if statement to assign a
// letter grade (A, B, C, D, or F) to a numeric test score.
\#include <iostream>
using namespace std;
int main()
{
// Constants for grade thresholds
const int A_SCORE = 90,
B_SCORE = 80,
C_SCORE = 70,
D_SCORE = 60;
int testScore; // To hold a numeric test score
// Get the numeric test score.
cout << "Enter your numeric test score and I will\n"
<< "tell you the letter grade you earned: ";
cin >> testScore;
// Determine the letter grade.
if (testScore >= A_SCORE)
cout << "Your grade is A.\n";
else if (testScore >= B_SCORE)
cout << "Your grade is B.\n";
else if (testScore >= C_SCORE)
cout << "Your grade is C.\n";
else if (testScore >= D_SCORE)
cout << "Your grade is D.\n";
else if (testScore >= 0)
cout << "Your grade is F.\n";
else
cout << "Invalid test score.\n";
return 0;
}

```

\section*{Program Output with Example Input Shown in Bold}

Enter your numeric test score and I will tell you the letter grade you earned: -1 Enter
Invalid test score.

\section*{The if/e1se if Statement Compared to a Nested Decision Structure}

You never have to use the if/else if statement because its logic can be coded with nested if/else statements. However, a long series of nested if/else statements has two particular disadvantages when you are debugging code:
- The code can grow complex and become difficult to understand.
- Because indenting is important in nested statements, a long series of nested if/else statements can become too long to be displayed on the computer screen without horizontal scrolling. Also, long statements tend to "wrap around" when printed on paper, making the code even more difficult to read.
The logic of an if/else if statement is usually easier to follow than that of a long series of nested if/else statements. And, because all of the clauses are aligned in an if/else if statement, the lengths of the lines in the statement tend to be shorter.

\section*{Checkpoint}
4.16 What will the following code display?
```

int funny = 7, serious = 15;
funny = serious % 2;
if (funny != 1)
{
funny = 0;
serious = 0;
}
else if (funny == 2)
{
funny = 10;
serious = 10;
}
else
{
funny = 1;
serious = 1;
}
cout << funny << "" << serious << endl;

```
4.17 The following code is used in a bookstore program to determine how many discount coupons a customer gets. Complete the table that appears after the program.
```

int numBooks, numCoupons;
cout << "How many books are being purchased? ";
cin >> numBooks;
if (numBooks < 1)
numCoupons = 0;
else if (numBooks < 3)
numCoupons = 1;
else if (numBooks < 5)
numCoupons = 2;

```
```

else
numCoupons = 3;
cout << "The number of coupons to give is "
<< numCoupons << endl;

```

If the customer purchases this many books This many coupons are given. 1 3 4 5

\subsection*{4.7 Flags}

CONCEPT: A flag is a Boolean or integer variable that signals when a condition exists.

A flag is typically a bool variable that signals when some condition exists in the program. When the flag variable is set to false, it indicates that the condition does not exist. When the flag variable is set to true, it means the condition does exist.

For example, suppose a program that calculates sales commissions has a bool variable, defined and initialized as shown here:
```

bool salesQuotaMet = false;

```

In the program, the salesQuotaMet variable is used as a flag to indicate whether a salesperson has met the sales quota. When we define the variable, we initialize it with false because we do not yet know if the salesperson has met the sales quota. Assuming a variable named sales holds the amount of sales, code similar to the following might be used to set the value of the salesQuotaMet variable:
```

if (sales >= QUOTA_AMOUNT)
salesQuotaMet = true;
else
salesQuotaMet = false;

```

As a result of this code, the salesQuotaMet variable can be used as a flag to indicate whether the sales quota has been met. Later in the program, we might test the flag in the following way:
```

if (salesQuotaMet)
cout << "You have met your sales quota!\n";

```

This code displays You have met your sales quota! if the bool variable salesQuotaMet is true. Notice we did not have to use the \(==\) operator to explicitly compare the salesQuotaMet variable with the value true. This code is equivalent to the following:
```

if (salesQuotaMet == true)
cout << "You have met your sales quota!\n";

```

\section*{Integer Flags}

Integer variables may also be used as flags. This is because in C++ the value 0 is considered false, and any nonzero value is considered true. In the sales commission program previously described, we could define the salesQuotaMet variable with the following statement:
```

int salesQuotaMet = 0; // 0 means false.

```

As before, we initialize the variable with 0 because we do not yet know if the sales quota has been met. After the sales have been calculated, we can use code similar to the following to set the value of the salesQuotaMet variable:
```

if (sales >= QUOTA_AMOUNT)
salesQuotaMet = 1;
else
salesQuotaMet = 0;

```

Later in the program, we might test the flag in the following way:
if (salesQuotaMet) cout << "You have met your sales quota!\n";

\subsection*{4.8 Logical Operators}

CONCEPT: Logical operators connect two or more relational expressions into one or reverse the logic of an expression.

In the previous section, you saw how a program tests two conditions with two if statements. In this section, you will see how to use logical operators to combine two or more relational expressions into one. Table 4-6 lists C++'s logical operators.
Table 4-6 Logical Operators
\begin{tabular}{lll}
\hline Operator & Meaning & Effect \\
\hline\(\& \&\) & AND & \begin{tabular}{l} 
Connects two expressions into one. Both expressions must be true for \\
the overall expression to be true.
\end{tabular} \\
I। & OR & \begin{tabular}{l} 
Connects two expressions into one. One or both expressions must be \\
true for the overall expression to be true. It is only necessary for one to \\
be true, and it does not matter which.
\end{tabular} \\
! & NOT & \begin{tabular}{l} 
The ! operator reverses the "truth" of an expression. It makes a true \\
expression false, and a false expression true.
\end{tabular} \\
\hline
\end{tabular}

\section*{The \&\& Operator}

The \&\& operator is known as the logical AND operator. It takes two expressions as operands and creates an expression that is true only when both subexpressions are true. Here is an example of an if statement that uses the \&\& operator:
```

if (temperature < 20 \&\& minutes > 12)
cout << "The temperature is in the danger zone.";

```

In the statement above, the two relational expressions are combined into a single expression. The cout statement will only be executed if temperature is less than 20 AND minutes is greater than 12 . If either relational test is false, the entire expression is false, and the cout statement is not executed.

TIP: You must provide complete expressions on both sides of the \&\& operator. For example, the following statement is not correct because the condition on the right side of the \&\& operator is not a complete expression:
```

temperature > 0 \&\& < 100

```

The expression must be rewritten as
temperature > 0 \&\& temperature < 100

Table 4-7 shows a truth table for the \&\& operator. The truth table lists all the possible combinations of values that two expressions may have, and the resulting value returned by the \&\& operator connecting the two expressions.

Table 4-7 Truth Table for the \&\& Operator
\begin{tabular}{ll}
\hline Expression & Value of Expression \\
\hline true \&\& false & false (0) \\
false \&\& true & false (0) \\
false \&\& false & false (0) \\
true \&\& true & true (1) \\
\hline
\end{tabular}

As the table shows, both subexpressions must be true for the \(\& \&\) operator to return a true value.

NOTE: If the subexpression on the left side of an \&\& operator is false, the expression on the right side will not be checked. Since the entire expression is false if only one of the subexpressions is false, it would waste CPU time to check the remaining expression. This is called short-circuit evaluation.

The \&\& operator can be used to simplify programs that otherwise would use nested if statements. Program 4-15 performs a similar operation as Program 4-11, which qualifies a bank customer for a special interest rate. This program uses a logical operator.

\section*{Program 4-15}
```

// This program demonstrates the \&\& logical operator.
\#include <iostream>
using namespace std;
int main()
{
char employed, // Currently employed, Y or N
recentGrad; // Recent graduate, Y or N
// Is the user employed and a recent graduate?
cout << "Answer the following questions\n";
cout << "with either Y for Yes or N for No.\n";

```

\section*{Program 4-15 (continued)}
```

14 cout << "Are you employed? ";
15 cin >> employed;
16
17
18
19
20
21 // Determine the user's loan qualifications.
if (employed == 'Y' \&\& recentGrad == 'Y')
23 {
24
25
26 }
27 else
28
29
30
31
32
}
33 return 0;
34 }

```

\section*{Program Output with Example Input Shown in Bold}

Answer the following questions
with either \(Y\) for Yes or \(N\) for No.
Are you employed? \(\mathbf{Y}\) Enter
Have you graduated from college in the past two years? \(\mathbf{N}\) Enter
You must be employed and have
graduated from college in the
past two years to qualify.

\section*{Program Output with Example Input Shown in Bold}

Answer the following questions
with either \(Y\) for Yes or \(N\) for No.
Are you employed? N Enter
Have you graduated from college in the past two years? Y Enter
You must be employed and have
graduated from college in the
past two years to qualify.

\section*{Program Output with Example Input Shown in Bold}

Answer the following questions
with either \(Y\) for Yes or \(N\) for No.
Are you employed? \(\mathbf{Y}\) Enter
Have you graduated from college in the past two years? Y Enter
You qualify for the special interest rate.
The message "You qualify for the special interest rate." is displayed only when both the expressions employed \(==\) ' \(Y\) ' and recentGrad \(==' Y\) ' are true. If either of these is false, the message "You must be employed and have graduated from college in the past two years to qualify." is printed.

NOTE: Although it is similar, Program 4-15 is not the logical equivalent of Program 4-11. For example, Program 4-15 doesn't display the message "You must be employed to qualify."

\section*{The || Operator}

The \|| operator is known as the logical OR operator. It takes two expressions as operands and creates an expression that is true when either of the subexpressions are true. Here is an example of an if statement that uses the \|| operator:
```

if (temperature < 20 || temperature > 100)
cout << "The temperature is in the danger zone.";

```

The cout statement will be executed if temperature is less than 20 OR temperature is greater than 100 . If either relational test is true, the entire expression is true and the cout statement is executed.

TIP: You must provide complete expressions on both sides of the \|| operator. For example, the following code is not correct because the condition on the right side of the || operator is not a complete expression:
temperature < \(0|\mid>100\)
The expression must be rewritten as
temperature < 0 || temperature > 100

Table 4-8 shows a truth table for the \| operator.
Table 4-8 Truth Table for the || Operator
\begin{tabular}{ll}
\hline \multicolumn{2}{l}{ Expression } \\
true || false & Value of the Expression \\
false || true & true (1) \\
false || false & true (1) \\
true || true & false (0) \\
\hline
\end{tabular}

All it takes for an OR expression to be true is for one of the subexpressions to be true. It doesn't matter if the other subexpression is false or true.

NOTE: The || operator also performs short-circuit evaluation. If the subexpression on the left side of an \|| operator is true, the expression on the right side will not be checked. Since it's only necessary for one of the subexpressions to be true, it would waste CPU time to check the remaining expression.

Program 4-16 performs different tests to qualify a person for a loan. This one determines if the customer earns at least \(\$ 35,000\) per year, or has been employed for more than 5 years.

\section*{Program 4-16}
```

// This program demonstrates the logical || operator.
\#include <iostream>
using namespace std;
int main()
{
// Constants for minimum income and years
const double MIN_INCOME = 35000.0;
const int MIN_YEARS = 5;
double income; // Annual income
int years; // Years at the current job
// Get the annual income
cout << "What is your annual income? ";
cin >> income;
// Get the number of years at the current job.
cout << "How many years have you worked at "
<< "your current job? ";
cin >> years;
// Determine the user's loan qualifications.
if (income >= MIN_INCOME || years > MIN_YEARS)
cout << "You qualify.\n";
else
{
cout << "You must earn at least \$"
<< MIN_INCOME << " or have been "
<< "employed more than " << MIN_YEARS
<< " years.\n";
}
return 0;
}

```

\section*{Program Output with Example Input Shown in Bold}

What is your annual income? 40000 Enter
How many years have you worked at your current job? 2 Enter
You qualify.

\section*{Program Output with Example Input Shown in Bold}

What is your annual income? 20000 Enter
How many years have you worked at your current job? 7 Enter
You qualify.

\section*{Program Output with Example Input Shown in Bold}

What is your annual income? 30000 Enter
How many years have you worked at your current job? 3 Enter
You must earn at least \(\$ 35000\) or have been employed more than 5 years.

The string "You qualify \(\backslash n\). " is displayed when either or both the expressions income >= 35000 or years > 5 are true. If both of these are false, the disqualifying message is printed.

\section*{The! Operator}

The! operator performs a logical NOT operation. It takes an operand and reverses its truth or falsehood. In other words, if the expression is true, the ! operator returns false, and if the expression is false, it returns true. Here is an if statement using the ! operator:
```

if (!(temperature > 100))
cout << "You are below the maximum temperature.\n";

```

First, the expression (temperature \(>100\) ) is tested to be true or false. Then the ! operator is applied to that value. If the expression (temperature \(>100\) ) is true, the ! operator returns false. If it is false, the ! operator returns true. In the example, it is equivalent to asking "is the temperature not greater than 100?"

Table 4-9 shows a truth table for the ! operator.

\section*{Table 4-9 Truth Table for the! Operator}
\begin{tabular}{ll}
\hline Expression & Value of the Expression \\
\hline\(!\) true & fa1se \((0)\) \\
! false & true \((1)\) \\
\hline
\end{tabular}

Program 4-17 performs the same task as Program 4-16. The if statement, however, uses the ! operator to determine if the user does not make at least \(\$ 35,000\), or has not been on the job more than 5 years.

\section*{Program 4-17}
```

// This program demonstrates the logical ! operator.
\#include <iostream>
using namespace std;
int main()
{
// Constants for minimum income and years
const double MIN_INCOME = 35000.0;
const int MIN_YEARS = 5;
double income; // Annual income
int years; // Years at the current job
// Get the annual income
cout << "What is your annual income? ";
cin >> income;
// Get the number of years at the current job.
cout << "How many years have you worked at "
<< "your current job? ";

```

\section*{Program 4-17 (continued)}
```

    cin >> years;
    // Determine the user's loan qualifications.
    if (!(income >= MIN_INCOME || years > MIN_YEARS))
    {
        cout << "You must earn at least $"
            << MIN_INCOME << " or have been "
            << "employed more than " << MIN_YEARS
            << " years.ln";
    }
        else
            cout << "You qualify.\n";
        return 0;
    }

```

The output of Program 4-17 is the same as Program 4-16.

\section*{Precedence and Associativity of Logical Operators}

Table 4-10 shows the precedence of C++'s logical operators, from highest to lowest.

\section*{Table 4-10 Precedence of Logical Operators}

Logical Operators in Order of Precedence
!
\&\&
11

The ! operator has a higher precedence than many of the C++ operators. To avoid an error, you should always enclose its operand in parentheses unless you intend to apply it to a variable or a simple expression with no other operators. For example, consider the following expressions:
\[
\begin{aligned}
& !(x>2) \\
& !x>2
\end{aligned}
\]

The first expression applies the ! operator to the expression \(x>2\). It is asking, "is \(x\) not greater than 2?" The second expression, however, applies the ! operator to \(x\) only. It is asking, "is the logical negation of \(x\) greater than 2 ?" Suppose \(x\) is set to 5 . Since 5 is nonzero, it would be considered true, so the ! operator would reverse it to false, which is 0 . The \(>\) operator would then determine if 0 is greater than 2 . To avoid a catastrophe like this, always use parentheses!

The \(\& \&\) and || operators rank lower in precedence than the relational operators, so precedence problems are less likely to occur. If you feel unsure, however, it doesn't hurt to use parentheses anyway.
```

(a>b) \&\& (x<y) is the same as a > b \&\& x < y
(x == y) || (b > a) is the same as x == y || b > a

```

The logical operators have left-to-right associativity. In the following expression, \(\mathrm{a}<\mathrm{b}\) is evaluated before \(y==z\).
```

a < b || y == z

```

In the following expression, \(y==z\) is evaluated first, however, because the \&\& operator has higher precedence than \|\|.
\[
a<b \| y==z \& \& m>j
\]

The expression is equivalent to
\[
(a<b)|\mid((y==z) \& \&(m>j))
\]

\subsection*{4.9 Checking Numeric Ranges with Logical Operators}

CONCEPT: Logical operators are effective for determining whether a number is in or out of a range.

When determining whether a number is inside a numeric range, it's best to use the \&\& operator. For example, the following if statement checks the value in \(x\) to determine whether it is in the range of 20 through 40:
```

if (x >= 20 \&\& x <= 40)
cout << x << " is in the acceptable range.\n";

```

The expression in the if statement will be true only when \(x\) is both greater than or equal to 20 AND less than or equal to 40 . \(x\) must be within the range of 20 through 40 for this expression to be true.

When determining whether a number is outside a range, the \|| operator is best to use. The following statement determines whether \(x\) is outside the range of 20 to 40 :
```

if (x < 20 || x > 40)
cout << x << " is outside the acceptable range.\n";

```

It's important not to get the logic of these logical operators confused. For example, the following if statement would never test true:
```

if (x < 20 \&\& x > 40)
cout << x << " is outside the acceptable range.\n";

```

Obviously, x cannot be less than 20 and at the same time greater than 40 .

NOTE: C++ does not allow you to check numeric ranges with expressions such as \(5<x<20\). Instead, you must use a logical operator to connect two relational expressions, as previously discussed.

\section*{Checkpoint}
4.18 The following truth table shows various combinations of the values true and false connected by a logical operator. Complete the table by indicating if the result of such a combination is True or False.
```

Logical Expression Result (True or False)
true \&\& false
true \&\& true
false \&\& true
false \&\& false
true || false
true || true
false || true
false || false
!true
!false

```
4.19 Assume the variables \(a=2, b=4\), and \(c=6\). Determine whether each of the following conditions is True or False:
A) \(a=4| | b>2\)
B) \(6<=c \& \& a>3\)
C) \(1 \quad!=b \quad \& \& \quad c \quad!=3\)
D) \(a>=-1| | a<=b\)
E) ! \((a>2)\)
4.20 Write an if statement that prints the message "The number is valid" if the variable speed is within the range 0 through 200.
4.21 Write an if statement that prints the message "The number is not valid" if the variable speed is outside the range 0 through 200.
4.10 Menus

CONCEPT: You can use nested if/else statements or the if/else if statement to create menu-driven programs. A menu-driven program allows the user to determine the course of action by selecting it from a list of actions.

A menu is a screen displaying a set of choices from which the user selects. For example, a program that manages a mailing list might give you the following menu:
1. Add a name to the list.
2. Remove a name from the list.
3. Change a name in the list.
4. Print the list.
5. Quit the program.

The user selects one of the operations by entering its number. Entering 4, for example, causes the mailing list to be printed, and entering 5 causes the program to end. Nested if/else statements or an if/else if structure can be used to set up such a menu. After the user enters a number, the program compares the number with the available selections and executes the statements that perform that operation.

Program 4-18 calculates the charges for membership in a health club. The club has three membership packages to choose from: standard adult membership, child membership, and
senior citizen membership. The program presents a menu that allows the user to choose the desired package then calculates the cost of the membership.

\section*{Program 4-18}
// This program displays a menu and asks the user to make a
// selection. An if/else if statement determines which item
// the user has chosen.
\#include <iostream>
\#include <iomanip>
using namespace std;
int main()
\{
    int choice; // To hold a menu choice
    int months; // To hold the number of months
    double charges; // To hold the monthly charges
    // Constants for membership rates
    const double ADULT = 40.0,
                SENIOR \(=30.0\),
                CHILD \(=20.0\);
    // Constants for menu choices
    const int ADULT_CHOICE = 1,
        CHILD_CHOICE = 2,
        SENIOR_CHOICE = 3,
        QUIT_CHOICE = 4;
    // Display the menu and get a choice.
    cout << "\t\tHealth Club Membership Menu\n\n"
        \(\ll\) "1. Standard Adult Membership\n"
        << "2. Child Membership\n"
        << "3. Senior Citizen Membership\n"
        << "4. Quit the Program\n\n"
        << "Enter your choice: ";
    cin >> choice;
    // Set the numeric output formatting.
    cout << fixed << showpoint << setprecision(2);
    // Respond to the user's menu selection.
    if (choice == ADULT_CHOICE)
    \{
        cout << "For how many months? ";
        cin >> months;
        charges \(=\) months * ADULT;
        cout << "The total charges are \$" << charges << end1;
    \}
    else if (choice == CHILD_CHOICE)
    \{
        cout << "For how many months? ";
```

Program 4-18 (continued)
8 cin >> months;
}

```

\section*{Program Output with Example Input Shown in Bold}

\author{
Health Club Membership Menu
}
1. Standard Adult Membership
2. Child Membership
3. Senior Citizen Membership
4. Quit the Program

Enter your choice: 3 Enter
For how many months? 6 Enter
The total charges are \(\$ 180.00\)
Let's take a closer look at the program:
- Lines 10-12 define the following variables:
- The choice variable will hold the user's menu choice.
- The months variable will hold the number of months of health club membership.
- The charges variable will hold the total charges.
- Lines 15-17 define named constants for the monthly membership rates for adult, senior citizen, and child memberships.
- Lines 20-23 define named constants for the menu choices.
- Lines \(26-32\) display the menu and get the user's choice.
- Line 35 sets the numeric output formatting for floating-point numbers.
- Lines 38-67 are an if/else if statement that determines the user's menu choice in the following manner:
- If the user selected 1 from the menu (adult membership), the statements in lines 40-43 are executed.
- Otherwise, if the user selected 2 from the menu (child membership), the statements in lines 47-50 are executed.
- Otherwise, if the user selected 3 from the menu (senior citizen membership), the statements in lines 54-57 are executed.
- Otherwise, if the user selected 4 from the menu (quit the program), the statement in line 61 is executed.
- If the user entered any choice other than \(1,2,3\), or 4 , the e 1 se clause in lines 63-67 executes, displaying an error message.

\subsection*{4.11 Focus on Software Engineering: Validating User Input}

CONCEPT: As long as the user of a program enters bad input, the program will produce bad output. Programs should be written to filter out bad input.

Perhaps the most famous saying of the computer world is "Garbage in, garbage out." The integrity of a program's output is only as good as its input, so you should try to make sure garbage does not go into your programs. Input validation is the process of inspecting data given to a program by the user and determining if it is valid. A good program should give clear instructions about the kind of input that is acceptable, and not assume the user has followed those instructions. Here are just a few examples of input validations performed by programs:
- Numbers are checked to ensure they are within a range of possible values. For example, there are 168 hours in a week. It is not possible for a person to be at work longer than 168 hours in one week.
- Values are checked for their "reasonableness." Although it might be possible for a person to be at work for 168 hours per week, it is not probable.
- Items selected from a menu or other sets of choices are checked to ensure they are available options.
- Variables are checked for values that might cause problems, such as division by zero.

Program 4-19 is a test scoring program that rejects any test score less than 0 or greater than 100.

\section*{Program 4-19}
// This test scoring program does not accept test scores
// that are less than 0 or greater than 100.
\#include <iostream>
using namespace std;
```

int main()

```
\{
// Constants for grade thresholds

\section*{Program 4-19 (continued)}
```

const int A_SCORE = 90,
B_SCORE = 80,
C_SCORE = 70,
D_SCORE = 60,
MIN_SCORE = 0, // Minimum valid score
MAX_SCORE = 100; // Maximum valid score
int testScore; // To hold a numeric test score
// Get the numeric test score.
cout << "Enter your numeric test score and I will\n"
<< "tell you the letter grade you earned: ";
cin >> testScore;
// Validate the input and determine the grade.
if (testScore >= MIN_SCORE \&\& testScore <= MAX_SCORE)
{
// Determine the letter grade.
if (testScore >= A_SCORE)
cout << "Your grade is A.\n";
else if (testScore >= B_SCORE)
cout << "Your grade is B.\n";
else if (testScore >= C_SCORE)
cout << "Your grade is C.\n";
else if (testScore >= D_SCORE)
cout << "Your grade is D.\n";
else
cout << "Your grade is F.\n";
}
e1se
{
// An invalid score was entered.
cout << "That is an invalid score. Run the program\n"
<< "again and enter a value in the range of\n"
<< MIN_SCORE << " through " << MAX_SCORE << ".\n";
}
return 0;
}

```

\section*{Program Output with Example Input Shown in Bold}

Enter your numeric test score and I will
tell you the letter grade you earned: -1 Enter
That is an invalid score. Run the program again and enter a value in the range of
0 through 100.

\section*{Program Output with Example Input Shown in Bold}

Enter your numeric test score and I will tell you the letter grade you earned: 81 Enter Your grade is B.

\subsection*{4.12 Comparing Characters and Strings}

\section*{CONCEPT: Relational operators can also be used to compare characters and string objects.}

Earlier in this chapter, you learned to use relational operators to compare numeric values. They can also be used to compare characters and string objects.

\section*{Comparing Characters}

As you learned in Chapter 3, characters are actually stored in memory as integers. On most systems, this integer is the ASCII value of the character. For example, the letter ' A ' is represented by the number 65 , the letter ' \(B\) ' is represented by the number 66 , and so on. Table \(4-11\) shows the ASCII numbers that correspond to some of the commonly used characters.

Table 4-11 ASCII Values of Commonly Used Characters
\begin{tabular}{ll}
\hline Character & ASCII Value \\
\hline '0'-'9' & \(48-57\) \\
'A'-'Z' & \(65-90\) \\
'a'-'z' & \(97-122\) \\
Blank & 32 \\
Period & 46 \\
\hline
\end{tabular}

Notice every character, even the blank, has an ASCII code associated with it. Notice also that the ASCII code of a character representing a digit, such as ' 1 ' or ' 2 ', is not the same as the value of the digit itself. A complete table showing the ASCII values for all characters can be found in Appendix A.

When two characters are compared, it is actually their ASCII values that are being compared. ' A ' < ' B ' because the ASCII value of ' A ' (65) is less than the ASCII value of ' B ' (66). Likewise ' 1 ' < ' 2 ' because the ASCII value of ' 1 ' (49) is less than the ASCII value of '2' (50). However, as shown in Table 4-11, lowercase letters have higher ASCII codes than uppercase letters, so ' a ' > ' Z '. Program 4-20 shows how characters can be compared with relational operators.

\section*{Program 4-20}
```

// This program demonstrates how characters can be
// compared with the relational operators.
\#include <iostream>
using namespace std;
int main()
{
char ch;

```
```

Program 4-20
(continued)
// Get a character from the user.
cout << "Enter a digit or a letter: ";
ch = cin.get();
// Determine what the user entered.
if (ch >= '0' \&\& ch <= '9')
cout << "You entered a digit.\n";
else if (ch >= 'A' \&\& ch <= 'Z')
cout << "You entered an uppercase letter.\n";
else if (ch >= 'a' \&\& ch <= 'z')
cout << "You entered a lowercase letter.\n";
else
cout << "That is not a digit or a letter.\n";
return 0;
}

```

\section*{Program Output with Example Input Shown in Bold}

Enter a digit or a letter: t Enter
You entered a lowercase letter.

\section*{Program Output with Example Input Shown in Bold}

Enter a digit or a letter: v Enter
You entered an uppercase letter.
Program Output with Example Input Shown in Bold
Enter a digit or a letter: 5 Enter
You entered a digit.
Program Output with Example Input Shown in Bold
Enter a digit or a letter: \& Enter
That is not a digit or a letter.

\section*{Comparing string Objects}
string objects can also be compared with relational operators. As with individual characters, when two string objects are compared, it is actually the ASCII values of the characters making up the strings that are being compared. For example, assume the following definitions exist in a program:
```

string str1 = "ABC";
string str2 = "XYZ";

```

The string object str1 is considered less than the string object str2 because the characters "ABC" alphabetically precede (have lower ASCII values than) the characters "XYZ". So, the following if statement will cause the message "str1 is less than str2." to be displayed on the screen.
```

if (str1 < str2)
cout << "str1 is less than str2.";

```

One by one, each character in the first operand is compared with the character in the corresponding position in the second operand. If all the characters in both string objects match, the two strings are equal. Other relationships can be determined if two characters in corresponding positions do not match. The first operand is less than the second operand if the first mismatched character in the first operand is less than its counterpart in the second operand. Likewise, the first operand is greater than the second operand if the first mismatched character in the first operand is greater than its counterpart in the second operand.

For example, assume a program has the following definitions:
```

string name1 = "Mary";
string name2 = "Mark";

```

The value in name1, "Mary", is greater than the value in name2, "Mark". This is because the first three characters in name1 have the same ASCII values as the first three characters in name2, but the ' y ' in the fourth position of "Mary" has a greater ASCII value than the ' k ' in the corresponding position of "Mark".

Any of the relational operators can be used to compare two string objects. Here are some of the valid comparisons of name 1 and name2:
```

name1 > name2 // true
name1 <= name2 // false
name1 != name2 // true

```
string objects can also, of course, be compared to string literals:
```

name1 < "Mary Jane" // true

```

Program 4-21 further demonstrates how relational operators can be used with string objects.

\section*{Program 4-21}
```

// This program uses relational operators to compare a string
// entered by the user with valid part numbers.
\#include <iostream>
\#include <iomanip>
\#include <string>
using namespace std;
int main()
{
const double PRICE_A = 249.0, // Price for part A
PRICE_B = 199.0; // Price for part B
string partNum; // Holds a part number
// Display available parts and get the user's selection
cout << "The headphone part numbers are:\n"
<< "Noise canceling: part number S-29A \n"
<< "Wireless: part number S-29B \n"
<< "Enter the part number of the headphones you\n"

```

\section*{Program 4-21 (continued)}
```

    << "wish to purchase: ";
    cin >> partNum;
    // Set the numeric output formatting
    cout << fixed << showpoint << setprecision(2);
    // Determine and display the correct price
    if (partNum == "S-29A")
        cout << "The price is $" << PRICE_A << endl;
    else if (partNum == "S-29B")
        cout << "The price is $" << PRICE_B << endl;
    else
        cout << partNum << " is not a valid part number.\n";
    return 0;
    }

```

\section*{Program Output with Example Input Shown in Bold}

The headphone part numbers are:
Noise canceling: part number S-29A
Wireless: part number S-29B
Enter the part number of the headphones you
wish to purchase: S-29A Enter
The price is \(\$ 249.00\)

\section*{Checkpoint}
4.22 Indicate whether each of the following relational expressions is True or False. Refer to the ASCII table in Appendix A if necessary.
A) 'a' < 'z'
B) 'a' == 'A'
C) \({ }^{\prime} 5\) ' < '7'
D) 'a' < 'A'
E) '1' == 1
F) '1' == 49
4.23 Indicate whether each of the following relational expressions is True or False. Refer to the ASCII table in Appendix A if necessary.
A) "Bill" == "BILL"
B) "Bill" < "BILL"
C) "Bill" < "Bob"
D) "189" > "23"
E) "189" > "Bill"
F) "Mary" < "MaryE1len"
G) "MaryEllen" < "Mary Ellen"

\subsection*{4.13 The Conditional Operator}

\section*{CONCEPT: You can use the conditional operator to create short expressions that work like \(\mathrm{if} / \mathrm{el}\) se statements.}

The conditional operator is powerful and unique. It provides a shorthand method of expressing a simple \(\mathrm{if} / \mathrm{e} 1\) se statement. The operator consists of the question-mark (?) and the colon (:). Its format is:
```

expression ? expression : expression;

```

Here is an example of a statement using the conditional operator:
\[
x<0 ? y=10: z=20
\]

The statement above is called a conditional expression and consists of three subexpressions separated by the ? and : symbols. The expressions are \(x<0, y=10\), and \(z=20\), as illustrated here:
```

x<0 ? y = 10 : z = 20;

```

NOTE: Since it takes three operands, the conditional operator is considered a ternary operator.

The conditional expression above performs the same operation as the following if/else statement:
```

if (x < 0)
y = 10;
else
z = 20;

```

The part of the conditional expression that comes before the question mark is the expression to be tested. It's like the expression in the parentheses of an if statement. If the expression is true, the part of the statement between the ? and the : is executed. Otherwise, the part after the : is executed. Figure 4-10 illustrates the roles played by the three subexpressions.

Figure 4-10 Conditional expression

If it helps, you can put parentheses around the subexpressions, as in the following:
```

(x<0) ? (y = 10) : (z = 20);

```

\section*{Using the Value of a Conditional Expression}

Remember, in C++ all expressions have a value, and this includes the conditional expression. If the first subexpression is true, the value of the conditional expression is the value of the second subexpression. Otherwise, it is the value of the third subexpression. Here is an example of an assignment statement using the value of a conditional expression:
```

a = x > 100 ? 0 : 1;

```

The value assigned to a will be either 0 or 1 , depending upon whether x is greater than 100 . This statement could be expressed as the following if/else statement:
```

if (x > 100)
a = 0;
else
a = 1;

```

Program 4-22 can be used to help a consultant calculate her charges. Her rate is \(\$ 50.00\) per hour, but her minimum charge is for 5 hours. The conditional operator is used in a statement that ensures the number of hours does not go below five.

\section*{Program 4-22}
```

// This program calculates a consultant's charges at \$50
// per hour, for a minimum of 5 hours. The ?: operator
// adjusts hours to 5 if less than 5 hours were worked.
\#include <iostream>
\#include <iomanip>
using namespace std;
int main()
{
const double PAY_RATE = 50.0; // Hourly pay rate
const int MIN_HOURS = 5; // Minimum billable hours
double hours, // Hours worked
charges; // Total charges
// Get the hours worked.
cout << "How many hours were worked? ";
cin >> hours;
// Determine the hours to charge for.
hours = hours < MIN_HOURS ? MIN_HOURS : hours;
// Calculate and display the charges.
charges = PAY_RATE * hours;
cout << fixed << showpoint << setprecision(2)
<< "The charges are \$" << charges << endl;
return 0;
}

```

\section*{Program Output with Example Input Shown in Bold \\ How many hours were worked? 10 Enter \\ The charges are \(\$ 500.00\) \\ Program Output with Example Input Shown in Bold \\ How many hours were worked? 2 Enter \\ The charges are \(\$ 250.00\)}

Notice in line 11 a constant named MIN_HOURS is defined to represent the minimum number of hours, which is 5 . Here is the statement in line 20, with the conditional expression:
```

hours = hours < MIN_HOURS ? MIN_HOURS : hours;

```

If the value in hours is less than 5 , then 5 is stored in hours. Otherwise, hours is assigned the value it already has. The hours variable will not have a value less than 5 when it is used in the next statement, which calculates the consultant's charges.

As you can see, the conditional operator gives you the ability to pack decision-making power into a concise line of code. With a little imagination, it can be applied to many other programming problems. For instance, consider the following statement:
```

cout << "Your grade is: " << (score < 60 ? "Fai1." : "Pass.");

```

If you were to use an \(\mathrm{if} / \mathrm{el}\) se statement, the statement above would be written as follows:
```

if (score < 60)
cout << "Your grade is: Fail.";
else
cout << "Your grade is: Pass.";

```

NOTE: The parentheses are placed around the conditional expression because the << operator has higher precedence than the ?: operator. Without the parentheses, just the value of the expression score < 60 would be sent to cout.

\section*{Checkpoint}
4.24 Rewrite the following \(\mathrm{if} / \mathrm{e} 1\) se statements as conditional expressions:
```

A) if ( $x>y$ )
$z=1 ;$
else
z = 20;
B) if (temp > 45)
population $=$ base * 10;
else
population $=$ base * 2;
C) if (hours > 40)
wages *= 1.5;
else
wages *= 1;
D) if (result >= 0)
cout << "The result is positive\n";
else
cout << "The result is negative. 1 n ";

```
4.25 The following statements use conditional expressions. Rewrite each with an if/ else statement.
A) \(\mathrm{j}=\mathrm{k}>90\) ? 57 : 12;
B) factor \(=x\) >= 10 ? \(y\) * 22 : \(y\) * 35 ;
C) total += count == 1 ? sales : count * sales;
D) cout << (((num \% 2) == 0) ? "Even\n" : "Odd \n");
4.26 What will the following program display?
```

\#include <iostream>
using namespace std;
int main()
{
const int UPPER = 8, LOWER = 2;
int num1, num2, num3 = 12, num4 = 3;
num1 = num3 < num4 ? UPPER : LOWER;
num2 = num4 > UPPER ? num3 : LOWER;
cout << num1 << " " << num2 << end1;
return 0;
}

```

\subsection*{4.14 The switch Statement}

CONCEPT: The switch statement lets the value of a variable or an expression determine where the program will branch.

A branch occurs when one part of a program causes another part to execute. The if/else if statement allows your program to branch into one of several possible paths. It performs a series of tests (usually relational) and branches when one of these tests is true. The switch statement is a similar mechanism. However, it tests the value of an integer expression and then uses that value to determine to which set of statements to branch. Here is the format of the switch statement:
```

switch (IntegerExpression)
{
case ConstantExpression:
// place one or more
// statements here
case ConstantExpression:
// place one or more
// statements here
// case statements may be repeated as many
// times as necessary
default:
// place one or more
// statements here
}

```

The first line of the statement starts with the word switch, followed by an integer expression inside parentheses. This can be either of the following:
- a variable of any of the integer data types (including char)
- an expression whose value is of any of the integer data types

On the next line is the beginning of a block containing several case statements. Each case statement is formatted in the following manner:
```

case ConstantExpression:
// place one or more
// statements here

```

After the word case is a constant expression (which must be of an integer type), followed by a colon. The constant expression may be an integer literal or an integer named constant. The case statement marks the beginning of a section of statements. The program branches to these statements if the value of the switch expression matches that of the case expression.

WARNING! The expression of each case statement in the block must be unique.

NOTE: The expression following the word case must be an integer literal or constant. It cannot be a variable, and it cannot be an expression such as \(x<22\) or \(n==50\).

An optional default section comes after all the case statements. The program branches to this section if none of the case expressions match the switch expression. So, it functions like a trailing else in an if/else if statement.

Program 4-23 shows how a simple switch statement works.

\section*{Program 4-23}
```

// The switch statement in this program tells the user something
// he or she already knows: the data just entered!
\#include <iostream>
using namespace std;
int main()
{
char choice;
cout << "Enter A, B, or C: ";
cin >> choice;
switch (choice)
{
case 'A': cout << "You entered A.\n";
break;
case 'B': cout << "You entered B.\n";
break;
case 'C': cout << "You entered C.\n";
break;
default: cout << "You did not enter A, B, or C!\n";
}
return 0;
}

```
```

Program 4-23
(continued)
Program Output with Example Input Shown in Bold
Enter A, B, or C: B Enter
You entered B.

```

\section*{Program Output with Example Input Shown in Bold}
```

Enter A, B, or C: F Enter
You did not enter A, B, or C!

```

The first case statement is case ' A ':, the second is case ' B ':, and the third is case ' C ':. These statements mark where the program is to branch to if the variable choice contains the values ' A ', ' B ', or ' C '. (Remember, character variables and literals are considered integers.) The default section is branched to if the user enters anything other than A, B, or C.

Notice the break statements in the case 'A', case 'B', and case 'C' sections.
```

switch (choice)
{
case 'A':cout << "You entered A.\n";
break;
case 'B':cout << "You entered B.\n";
break;
case 'C':cout << "You entered C.\n";
break;
default: cout << "You did not enter A, B, or C!\n";
}

```

The case statements show the program where to start executing in the block, and the break statements show the program where to stop. Without the break statements, the program would execute all of the lines from the matching case statement to the end of the block.

NOTE: The default section (or the last case section, if there is no default) does not need a break statement. Some programmers prefer to put one there anyway, for consistency.

Program 4-24 is a modification of Program 4-23, without the break statements.

\section*{Program 4-24}
```

// The switch statement in this program tells the user something
// he or she already knows: the data just entered!
\#include <iostream>
using namespace std;
int main()
{
char choice;

```
```

10 cout << "Enter A, B, or C: ";
11 cin >> choice;
12 // The following switch is
13
14
15
16
1 7
18
19
20
21 return 0;
22 }

```

\section*{Program Output with Example Input Shown in Bold}

Enter A, B, or C: A Enter
You entered \(A\).
You entered \(B\).
You entered C
You did not enter A, B, or C!

\section*{Program Output with Example Input Shown in Bold}
```

Enter A, B, or C: C Enter
You entered C.
You did not enter A, B, or C!

```

Without the break statement, the program "falls through" all of the statements below the one with the matching case expression. Sometimes this is what you want. Program 4-25 lists the features of three TV models a customer may choose from. The Model 100 has remote control. The Model 200 has remote control and stereo sound. The Model 300 has remote control, stereo sound, and picture-in-a-picture capability. The program uses a switch statement with carefully omitted breaks to print the features of the selected model.

\section*{Program 4-25}
```

// This program is carefully constructed to use the "fall through"
// feature of the switch statement.
\#include <iostream>
using namespace std;
int main()
{
int modelNum; // Model number
// Get a model number from the user.
cout << "Our TVs come in three models:\n";
cout << "The 100, 200, and 300. Which do you want? ";
cin >> modelNum;

```
```

Program 4-25
(continued)

```
```

    // Display the model's features.
    cout << "That model has the following features:\n";
    switch (modelNum)
    {
        case 300: cout << "\tPicture-in-a-picture.\n";
        case 200: cout << "\tStereo sound.\n";
        case 100: cout << "\tRemote control.\n";
        break;
        default: cout << "You can only choose the 100,";
            cout << "200, or 300.\n";
        }
        return 0;
    ```
Program Output with Example Input Shown in Bold
Our TVs come in three models:
The 100,200 , and 300 . Which do you want? 100 Enter
That model has the following features:
    Remote control.

\section*{Program Output with Example Input Shown in Bold}

Our TVs come in three models:
The 100,200 , and 300 . Which do you want? 200 Enter
That model has the following features:
Stereo sound.
Remote control.

\section*{Program Output with Example Input Shown in Bold}

Our TVs come in three models:
The 100, 200, and 300. Which do you want? \(\mathbf{3 0 0}\) Enter
That model has the following features:
Picture-in-a-picture.
Stereo sound.
Remote control.
Program Output with Example Input Shown in Bold
Our TVs come in three models:
The 100, 200, and 300. Which do you want? 500 Enter
That model has the following features:
You can only choose the 100,200 , or 300.
Another example of how useful this "fall through" capability can be is when you want the program to branch to the same set of statements for multiple case expressions. For instance, Program 4-26 asks the user to select a grade of pet food. The available choices are A, B, and C. The switch statement will recognize either upper or lowercase letters.

\section*{Program 4-26}
```

1 // The switch statement in this program uses the "fall through"
2 // feature to catch both uppercase and lowercase letters entered
3 // by the user.
4 \#include <iostream>

```
```

using namespace std;
int main()
{
char feedGrade;
// Get the desired grade of feed.
cout << "Our pet food is available in three grades:\n";
cout << "A, B, and C. Which do you want pricing for? ";
cin >> feedGrade;
// Display the price.
switch(feedGrade)
{
case 'a':
case 'A': cout << "30 cents per pound.\n";
break;
case 'b':
case 'B': cout << "20 cents per pound.\n";
break;
case 'c':
case 'C': cout << "15 cents per pound.\n";
break;
default: cout << "That is an invalid choice.\n";
}
return 0;
}

```

\section*{Program Output with Example Input Shown in Bold}

Our pet food is available in three grades:
A, B, and C. Which do you want pricing for? benter
20 cents per pound.

\section*{Program Output with Example Input Shown in Bold}

Our pet food is available in three grades:
A, B, and C. Which do you want pricing for? B Enter
20 cents per pound.
When the user enters 'a', the corresponding case has no statements associated with it, so the program falls through to the next case, which corresponds with ' A '.
```

case 'a':
case 'A': cout << "30 cents per pound.\n";
break;

```

The same technique is used for ' b ' and ' c '.

\section*{Using switch in Menu Systems}

The switch statement is a natural mechanism for building menu systems. Recall that Program 4-18 gives a menu to select which health club package the user wishes to purchase. The program uses if/else if statements to determine which package the user has selected and displays the calculated charges. Program 4-27 is a modification of that program, using a switch statement instead of if/else if.

\section*{Program 4-27}
```

// This program uses a switch statement to determine
// the item selected from a menu.
\#include <iostream>
\#include <iomanip>
using namespace std;
int main()
{
int choice; // To hold a menu choice
int months; // To hold the number of months
double charges; // To hold the monthly charges

```
// Constants for membership rates
const double ADULT \(=40.0\),
CHILD \(=20.0\),
SENIOR = 30.0;
// Constants for menu choices
const int ADULT_CHOICE = 1,
    CHILD_CHOICE = 2,
    SENIOR_CHOICE = 3,
    QUIT_CHOICE = 4;
// Display the menu and get a choice.
cout << "\t\tHealth Club Membership Menu\n\n"
    \(\ll\) "1. Standard Adult Membership\n"
    << "2. Child Membership\n"
    << "3. Senior Citizen Membership\n"
    << "4. Quit the Program\n\n"
    << "Enter your choice: ";
    cin >> choice;
    // Set the numeric output formatting.
    cout << fixed << showpoint << setprecision(2);
    // Respond to the user's menu selection.
    switch (choice)
    \{
        case ADULT_CHOICE:
            cout << "For how many months? ";
            cin >> months;
            charges \(=\) months * ADULT;
            cout << "The total charges are \$" << charges << end1;
            break;
        case CHILD_CHOICE:
            cout << "For how many months? ";
            cin >> months;
            charges \(=\) months * CHILD;
            cout << "The total charges are \$" << charges << endl;
            break;
```

53
54
5
56
57
58
59
60
6 1
6 2
6 3
6 4
6
6 6
6 7
68
return 0;
}

```

\section*{Program Output with Example Input Shown in Bold}

Health Club Membership Menu
1. Standard Adult Membership
2. Child Membership
3. Senior Citizen Membership
4. Quit the Program

Enter your choice: 2 Enter
For how many months? 6 Enter
The total charges are \(\$ 120.00\)

\section*{Checkpoint}
4.27 Explain why you cannot convert the following if/else if statement into a switch statement.
```

if (temp == 100)
x = 0;
else if (population > 1000)
x = 1;
else if (rate < .1)
x = -1;

```
4.28 What is wrong with the following switch statement?
```

switch (temp)
{
case temp < O : cout << "Temp is negative.\n";
break;
case temp == 0: cout << "Temp is zero.\n";
break;
case temp > 0 : cout << "Temp is positive.\n";
break;
}

```
4.29 What will the following program display?
```

\#include <iostream>
using namespace std;
int main()
{
int funny = 7, serious = 15;
funny = serious * 2;
switch (funny)
{ case 0 : cout << "That is funny.\n";
break;
case 30: cout << "That is serious.\n";
break;
case 32: cout << "That is seriously funny.\n";
break;
default: cout << funny << endl;
}
return 0;
}

```
4.30 Complete the following program skeleton by writing a switch statement that displays "one" if the user has entered 1, "two" if the user has entered 2, and "three" if the user has entered 3 . If a number other than 1,2 , or 3 is entered, the program should display an error message.
```

\#include <iostream>
using namespace std;
int main()
{
int userNum;
cout << "Enter one of the numbers 1, 2, or 3: ";
cin >> userNum;
|/
// Write the switch statement here.
|
return 0;
}

```
4.31 Rewrite the following program. Use a switch statement instead of the if/else if statement.
```

\#include <iostream>
using namespace std;
int main()
{
int selection;
cout << "Which formula do you want to see?\n\n";
cout << "1. Area of a circle\n";
cout << "2. Area of a rectangle\n";
cout << "3. Area of a cylinder\n"
cout << "4. None of them!\n";
cin >> selection;
if (selection == 1)
cout << "Pi times radius squared\n";

```
```

    else if (selection == 2)
        cout << "Length times width\n";
    else if (selection == 3)
        cout << "Pi times radius squared times height\n";
    else if (selection == 4)
    cout << "Well okay then, good bye!\n";
    else
        cout << "Not good with numbers, eh?\n";
    return 0;
    }

```

\subsection*{4.15 More about Blocks and Variable Scope}

CONCEPT: The scope of a variable is limited to the block in which it is defined.
C++ allows you to create variables almost anywhere in a program. Program 4-28 is a modification of Program 4-17, which determines if the user qualifies for a loan. The definitions of the variables income and years have been moved to later points in the program.

\section*{Program 4-28}
// This program demonstrates late variable definition \#include <iostream>
using namespace std;
int main()
\{
// Constants for minimum income and years
const double MIN_INCOME = 35000.0;
const int MIN_YEARS = 5;
// Get the annual income.
cout << "What is your annual income? ";
double income; // Variable definition
cin >> income;
// Get the number of years at the current job.
cout << "How many years have you worked at "
<< "your current job? ";
int years; // Variable definition
cin >> years;
// Determine the user's loan qualifications.
if (income >= MIN_INCOME || years > MIN_YEARS) cout << "You qualify. 1 n";
else
\{
cout << "You must earn at least \$"
<< MIN_INCOME << " or have been " << "employed more than " << MIN_YEARS << " years.ln";
\}
return 0;
\}

It is a common practice to define all of a function's variables at the top of the function. Sometimes, especially in longer programs, it's a good idea to define variables near the part of the program where they are used. This makes the purpose of the variable more evident.

Recall from Chapter 2 that the scope of a variable is defined as the part of the program where the variable may be used.

In Program 4-28, the scope of the income variable is the part of the program in lines 13 through 32. The scope of the years variable is the part of the program in lines 19 through 32.
The variables income and years are defined inside function main's braces. Variables defined inside a set of braces have local scope or block scope. They may only be used in the part of the program between their definition and the block's closing brace.
You may define variables inside any block. For example, look at Program 4-29. This version of the loan program has the variable years defined inside the block of the if statement. The scope of years is the part of the program in lines 21 through 31 .

\section*{Program 4-29}
```

// This program demonstrates a variable defined in an inner block.
\#include <iostream>
using namespace std;
int main()
{
// Constants for minimum income and years
const double MIN_INCOME = 35000.0;
const int MIN_YEARS = 5;
// Get the annual income.
cout << "What is your annual income? ";
double income; // Variable definition
cin >> income;
if (income >= MIN_INCOME)
{
// Get the number of years at the current job.
cout << "How many years have you worked at "
<< "your current job? ";
int years; // Variable definition
cin >> years;
if (years > MIN_YEARS)
cout << "You qualify.\n";
else
{
cout << "You must have been employed for\n"
<< "more than " << MIN_YEARS
<< " years to qualify.\n";
}
}
else

```
```

    {
        cout << "You must earn at least $" << MIN_INCOME
        << " to qualify.\n";
        }
        return 0;
    }

```

Notice the scope of years is only within the block where it is defined. The variable is not visible before its definition or after the closing brace of the block. This is true of any variable defined inside a set of braces.

NOTE: When a program is running and it enters the section of code that constitutes a variable's scope, it is said that the variable comes into scope. This simply means the variable is now visible and the program may reference it. Likewise, when a variable leaves scope, or goes out of scope, it may no longer be used.

\section*{Variables with the Same Name}

When a block is nested inside another block, a variable defined in the inner block may have the same name as a variable defined in the outer block. As long as the variable in the inner block is visible, however, the variable in the outer block will be hidden. This is illustrated by Program 4-30.

\section*{Program 4-30}
```

// This program uses two variables with the name number.
\#include <iostream>
using namespace std;
int main()
{
// Define a variable named number.
int number;
cout << "Enter a number greater than 0: ";
cin >> number;
if (number > 0)
{
int number; // Another variable named number.
cout << "Now enter another number: ";
cin >> number;
cout << "The second number you entered was "
<< number << endl;
}
cout << "Your first number was " << number << end1;
return 0;
}

```

\section*{Program Output with Example Input Shown in Bold}

Enter a number greater than 0: 2 Enter
Now enter another number: 7 Enter
The second number you entered was 7
Your first number was 2

Program 4-30 has two separate variables named number. The cin and cout statements in the inner block (belonging to the if statement) can only work with the number variable defined in that block. As soon as the program leaves that block, the inner number goes out of scope, revealing the outer number variable.

WARNING! Although it's perfectly acceptable to define variables inside nested blocks, you should avoid giving them the same names as variables in the outer blocks. It's too easy to confuse one variable with another.

Case Study: See the Sales Commission Case Study on the computer science portal at www.pearsonglobaleditions.com/gaddis.

\section*{Review Questions and Exercises}

\section*{Short Answer}
1. Describe the difference between the if/else if statement and a series of if statements.
2. In an if/else if statement, what is the purpose of a trailing else?
3. What is a flag and how does it work?
4. Can an if statement test expressions other than relational expressions? Explain.
5. Briefly describe how the \&\& operator works.
6. Briefly describe how the || operator works.
7. Why are the relational operators called relational?
8. Why do most programmers indent the conditionally executed statements in a decision structure?

\section*{Fill-in-the-Blank}
9. An expression using the greater-than, less-than, greater-than-or-equal-to, less-than-or-equal-to, equal-to, or not-equal-to operator is called a(n) \(\qquad\) expression.
10. A relational expression is either \(\qquad\) or \(\qquad\) .
11. If the values of variables \(x\) and \(y\) are 5 and 10, respectively, the relational expression \(x<=y\) will evaluate to \(\qquad\) .
12. The if statement regards an expression with the value 0 as \(\qquad\) .
13. The relational expression if \((-1)\) will evaluate to \(\qquad\) .
14. For an if statement to conditionally execute a group of statements, the statements must be enclosed in a set of \(\qquad\) ـ.
15. In an if/else statement, the if part executes its statement or block if the expression is \(\qquad\) , and the else part executes its statement or block if the expression is
\(\qquad\) .
16. The trailing else in an if/else if statement has a similar purpose as the \(\qquad\) section of a switch statement.
17. A relational operator has \(\qquad\) precedence over a binary arithmetic operator.
18. If the subexpression on the left of the \(\qquad\) logical operator is false, the right subexpression is not checked.
19. If the subexpression on the left of the \(\qquad\) logical operator is true, the right subexpression is not checked.
20. The \(\qquad\) logical operator has higher precedence than the other logical operators.
21. A flag variable generally has a data type \(\qquad\) or \(\qquad\) _.
22. The \(\qquad\) logical operator works best when testing a number to determine if it is within a range.
23. The \(\qquad\) logical operator evaluates to true if the relational expression is false and evaluates to false if the relational expression is true.
24. A variable with \(\qquad\) scope is only visible when the program is executing in the block containing the variable's definition.
25. You use the \(\qquad\) operator to determine whether one string object is greater than another string object.
26. The value of a after execution of the statement a \(=1\) ? \(0: 1\) will be \(\qquad\) .
27. The \(\qquad\) in a switch block is executed when none of the case values match.
28. The expression following a case statement must be a(n) \(\qquad\) .
29. A break statement within a block transfers the control to the \(\qquad\) of the block.
30. What value will be stored in the variable \(t\) after each of the following statements executes?
A) \(t=(12>1)\); \(\qquad\)
B) \(\mathrm{t}=(2<0)\); \(\qquad\)
C) \(t=(5=(3 * 2))\); \(\qquad\)
D) \(t=(5==5)\); \(\qquad\)

\section*{Algorithm Workbench}
31. Write an if statement that assigns half of \(x\) to \(y\) when \(x\) is even.
32. Write an if statement that prints the square root of a number num if its value is nonnegative, and prints "Error" otherwise.
33. Using the following chart, write an if/else if statement that assigns \(.10, .15\), or .20 to commission, depending on the value in sales.
\begin{tabular}{ll}
\hline Sales & Commission Rate \\
\hline Up to \(\$ 10,000\) & \(10 \%\) \\
\(\$ 10,000\) to \(\$ 15,000\) & \(15 \%\) \\
Over \(\$ 15,000\) & \(20 \%\) \\
\hline
\end{tabular}
34. Write an if statement that sets the variable hours to 10 when the flag variable minimum is set.
35. Write nested if statements that perform the following tests: If amount1 is greater than 10 and amount2 is less than 100, display the greater of the two.
36. Write an if statement that prints "Age is valid", if the value of the variable employeeAge is within the range 18 through 65, and prints "Invalid Age" otherwise.
37. Write an if statement that prints the message "Time is valid" if the variable hours is within the range 0 through 23 and the variable minutes is within the range 0 through 59 .
38. Write a conditional expression that prints "Negative" if the variable number is less than 0 and "Positive" otherwise.
39. Assume str1 and str2 are string objects that have been initialized with different values. Write an if/else statement that compares the two objects and displays the one that is alphabetically greatest.
40. Convert the following if/else if statement into a switch statement:
```

if (choice == 1)
{
cout << fixed << showpoint << setprecision(2);
}
else if (choice == 2 || choice == 3)
{
cout << fixed << showpoint << setprecision(4);
}
else if (choice == 4)
{
cout << fixed << showpoint << setprecision(6);
}
else
{
cout << fixed << showpoint << setprecision(8);
}

```
41. Match the conditional expression with the if/else statement that performs the same operation.
A) \(q=x<y\) ? \(a+b: x\) * 2 ;
B) \(q=x<y\) ? \(x\) * 2 : \(a+b ;\)
C) \(x<y\) ? \(q=0\) : \(q=1\);
\[
\text { __ if }(x<y)
\]
\[
q=0 ;
\]
else
\(q=1 ;\)
\(\qquad\) if ( \(x\) < \(y\) )
\(q=a+b ;\) else
\(\mathrm{q}=\mathrm{x}\) * 2;
___ if \((x<y)\)
\(q=x\) * 2;
else
\(\mathrm{q}=\mathrm{a}+\mathrm{b}\);

\section*{True or False}
42. T F The = operator and the == operator perform the same operation when used in a Boolean expression.
43. T F A nested if/else block with another if/else block facilitates checking of multiple conditions.
44. T F A conditionally executed statement should be indented one level from the if statement.
45. \(\mathrm{T} \quad \mathrm{F}\) The compiler reports an error if lines within a block are not indented.
46. T F It's safe to assume that all uninitialized variables automatically start with 0 as their value.
47. \(T \quad F\) If an if statement is nested within the if part of another statement, the block within the inner if is executed when both the conditions are false.
48. \(\mathrm{T} F \mathrm{~F}\) When an if statement is nested in the else part of another statement, as in an \(i f / e 1\) se \(i f\), the only time the inner if is executed is when the expression of the outer if is true.
49. \(\mathrm{T} \quad \mathrm{F}\) The scope of a variable is limited to the block in which it is defined.
50. T F You can use the relational operators to compare string objects.
51. T F The expression 'a' == 'A' || \(0==0\) is true.
52. T \(\mathrm{F} \quad \mathrm{y}<\mathrm{x}\) is the same as \(\mathrm{x}>=\mathrm{y}\)
53. \(\mathrm{T} F \quad \mathrm{~F}>=\mathrm{y}\) is the same as \((\mathrm{x}>\mathrm{y} \& \& \mathrm{x}=\mathrm{y})\)

Assume the variables \(x=5, y=6\), and \(z=8\). Indicate by circling the \(T\) or \(F\) whether each of the following conditions is True or False:
54. \(\mathrm{T} \mathrm{F} \quad \mathrm{x}==5 \| \mathrm{y}>3\)
55. \(\mathrm{T} F \mathrm{~F}==5\) \&\& \((\mathrm{y}<=10| | \mathrm{z}>10)\)
56. T F 2 ! \(=\) y \&\& \(z \quad!=4\)
57. T F ! \((x<5 \quad \& \& \quad z>5)\)

\section*{Find the Errors}

Each of the following programs has errors. Find as many as you can.
```

58. // This program averages 3 test scores.
// It uses the variable perfectScore as a flag.
include <iostream>
using namespace std;
int main()
{
cout << "Enter your 3 test scores and I wil1 ";
<< "average them:";
int score1, score2, score3,
cin >> score1 >> score2 >> score3;
double average;
average = (score1 + score2 + score3) / 3.0;
if (average = 100);
perfectScore = true; /l Set the flag variable
cout << "Your average is " << average << endl;
bool perfectScore;
if (perfectScore);
{
cout << "Congratulations!\n";
cout << "That's a perfect score.\n";
cout << "You deserve a pat on the back!\n";
return 0;
}
```
```

59. // This program divides a user-supplied number by another
// user-supplied number. It checks for division by zero.
\#include <iostream>
using namespace std;
int main()
{
double num1, num2, quotient;
cout << "Enter a number: ";
cin >> num1;
cout << "Enter another number: ";
cin >> num2;
if (num2 == 0)
cout << "Division by zero is not possible.\n";
cout << "Please run the program again ";
cout << "and enter a number besides zero.ln";
else
quotient = num1 / num2;
cout << "The quotient of " << num1 <<
cout << " divided by " << num2 << " is ";
cout << quotient << endl;
return 0;
}
60. // This program uses an if/else if statement to assign a // letter grade (A, B, C, D, or F) to a numeric test score. \#include <iostream>
using namespace std;
int main()
{
int testScore;
cout << "Enter your test score and I will tell you\n";
cout << "the letter grade you earned: ";
cin >> testScore;
if (testScore < 60)
cout << "Your grade is F.ln";
else if (testScore < 70)
cout << "Your grade is D.\n";
else if (testScore < 80)
cout << "Your grade is C.ln";
else if (testScore < 90)
cout << "Your grade is B.\n";
else
cout << "That is not a valid score.\n";
else if (testScore <= 100)
cout << "Your grade is A.ln";
return 0;
}
```
61. // This program uses a switch-case statement to assign a // letter grade (A, B, C, D, or F) to a numeric test score. \#include <iostream> using namespace std;
int main()
\{ double testScore;
    cout << "Enter your test score and I will tell youln";
    cout << "the letter grade you earned: ";
    cin >> testScore;
    switch (testScore)
    \{
        case (testScore < 60.0):
                                    cout << "Your grade is F.ln";
                                    break;
        case (testScore < 70.0):
                        cout << "Your grade is D. In";
                        break;
        case (testScore < 80.0):
                        cout << "Your grade is C.In";
                        break;
        case (testScore < 90.0):
                        cout << "Your grade is B.ln";
                        break;
        case (testScore <= 100.0):
                        cout << "Your grade is A.ln";
                        break;
        default:
                        cout << "That score isn't valid\n";
        return 0 ;
\}
62. The following statement should determine if \(x\) is not greater than 20 . What is wrong with it?
if (! \(x>20\) )
63. The following statement should determine if count is within the range of 0 through 100. What is wrong with it?
if (count >= 0 || count <= 100)
64. The following statement should determine if count is outside the range of 0 through 100. What is wrong with it?
if (count < 0 \&\& count > 100)
65. The following statement assigns ( \(0.1^{*}\) income) to tax if income is greater than 200,000, otherwise assigns 0 to tax. What is wrong with it?
```

tax = (income>200000)?(0.1*income::0);

```

\section*{Programming Challenges}

\section*{1. Absolute of a Number}

The absolute of a number is its value without the sign. Write a program that asks the user to enter a number and finds the absolute of the number using the conditional operator.

\section*{2. Age Check}

A company is hiring new recruits who should be within 18 to 28 years of age. Write a program that asks the user to input the current year and an applicant's year of birth. It then displays the age and a message indicating whether the applicant is eligible.

\section*{3. Magic Dates}

The date June 10, 1960 is special because when we write it in the following format, the month times the day equals the year.

\section*{6/10/60}

Write a program that asks the user to enter a month (in numeric form), a day, and a two-digit year. The program should then determine whether the month times the day is equal to the year. If so, it should display a message saying the date is magic. Otherwise, it should display a message saying the date is not magic.

\section*{4. Areas of Rectangles}

The area of a rectangle is the rectangle's length times its width. Write a program that asks for the length and width of two rectangles. The program should tell the user which rectangle has the greater area, or if the areas are the same.

\section*{5. Zero Points of a Quadratic Equation}

A quadratic equation (from the Latin quadratus for "square") is an equation of the form
\[
a x^{2}+b x+c=0
\]
where \(x\) is the unknown variable, and \(a, b\), and \(c\) are coefficients of the equation. The value of the discriminant determines whether a quadratic equation has a real solution or not, and how many solutions it can have. When the discriminant is less than zero, the quadratic equation has no real solution. When the discriminant equals zero, there is exactly one solution; otherwise, there are two solutions. The formula for the discriminant \(D\) is
\[
D^{2}=b^{2}-4 a c
\]

Write a program that asks the user to input the coefficients \(a, b\), and \(c\) and then displays the number of real solutions for the corresponding quadratic equation. It is not required to calculate the actual solutions.

\section*{6. Triangle Construction}

In a triangle, the sum of any two sides is always greater than the third side. Write a program that prompts the user to input the length of three lines. It then determines whether the three lines can be used to construct a triangle. If a triangle can be constructed, then compute the area of the triangle.
Note that the area of a triangle can be calculated using the following formula, where
\(s=\frac{(a+b+c)}{2}\) and \(a, b\), and \(c\) are the lengths of the sides:
area \(=\sqrt{s(s-a)(s-b)(s-c)}\)

\section*{7. Time Calculator}

Write a program that asks the user to enter a number of seconds.
- There are 60 seconds in a minute. If the number of seconds entered by the user is greater than or equal to 60 , the program should display the number of minutes in that many seconds.
- There are 3,600 seconds in an hour. If the number of seconds entered by the user is greater than or equal to 3,600 , the program should display the number of hours in that many seconds.
- There are 86,400 seconds in a day. If the number of seconds entered by the user is greater than or equal to 86,400 , the program should display the number of days in that many seconds.

\section*{8. Color Mixer}

The colors red, blue, and yellow are known as primary colors because they cannot be made by mixing other colors. When you mix two primary colors, you get a secondary color, as shown here:

When you mix red and blue, you get purple.
When you mix red and yellow, you get orange.
When you mix blue and yellow, you get green.
Write a program that prompts the user to enter the names of two primary colors to mix. If the user enters anything other than "red," "blue," or "yellow," the program should display an error message. Otherwise, the program should display the name of the secondary color that results by mixing two primary colors.

\section*{9. Middle of Three Numbers}

Write a program that lets the user input three numbers and outputs the number whose value is between the other two. This sounds like a very easy program, but it is not as straightforward as it sounds. This is a typical example of a task that is trivial for a human, but one that many people find hard to express in a program. Test at least for the values 1,2 , and 3 and for the values 3,2 , and 1 .

\section*{10. Days in a Month}

Write a program that asks the user to enter the month (letting the user enter an integer in the range of 1 through 12) and the year. The program should then display the number of days in that month. Use the following criteria to identify leap years:
1. Determine whether the year is divisible by 100 . If it is, then it is a leap year if and only if it is divisible by 400 . For example, 2000 is a leap year but 2100 is not.
2. If the year is not divisible by 100 , then it is a leap year if and only if it is divisible by 4. For example, 2008 is a leap year but 2009 is not.

Here is a sample run of the program:
```

Enter a month (1-12): 2 Enter
Enter a year: 2008 Enter
29 days

```

\section*{11. Math Tutor}

This is a modification of Programming Challenge 17 from Chapter 3. Write a program that can be used as a math tutor for a young student. The program should display two random numbers that are to be added, such as:
\[
247
\]
\[
\begin{array}{r}
+129 \\
\hline
\end{array}
\]

The program should wait for the student to enter the answer. If the answer is correct, a message of congratulations should be printed. If the answer is incorrect, a message should be printed showing the correct answer.

\section*{12. Software Sales}

A software company sells a package that retails for \(\$ 99\). Quantity discounts are given according to the following table.
\begin{tabular}{ll}
\hline Quantity & Discount \\
\hline \(10-19\) & \(20 \%\) \\
\(20-49\) & \(30 \%\) \\
\(50-99\) & \(40 \%\) \\
100 or more & \(50 \%\) \\
\hline
\end{tabular}

Write a program that asks for the number of units sold and computes the total cost of the purchase.
Input Validation: Make sure the number of units is greater than 0.

\section*{13. Book Club Points}

Serendipity Booksellers has a book club that awards points to its customers based on the number of books purchased each month. The points are awarded as follows:
- If a customer purchases 0 books, he or she earns 0 points.
- If a customer purchases 1 book, he or she earns 5 points.
- If a customer purchases 2 books, he or she earns 15 points.
- If a customer purchases 3 books, he or she earns 30 points.
- If a customer purchases 4 or more books, he or she earns 60 points.

Write a program that asks the user to enter the number of books he or she has purchased this month then displays the number of points awarded.

\section*{14. Membership Fees}

An organization wishing to attract more people decides to base its membership fees on the age of the member. Also, wanting members to attend more activities, it gives a reduction on the membership fee for each activity attended in the previous year.
The following table depicts the corresponding fee and reductions. The minimum membership fee is \(\$ 1\), even if the member attended a lot of activities.
\begin{tabular}{lll}
\hline Age & Membership Fee & Reduction per Activity \\
\hline 6 years or less & \(\$ 5\) & \(\$ 0.75\) \\
\(7-12\) years & \(\$ 10\) & \(\$ 1.25\) \\
\(13-18\) years & \(\$ 15\) & \(\$ 2\) \\
Over 18 years & \(\$ 25\) & \(\$ 2\) \\
\hline
\end{tabular}

Write a program that asks the user to input their age and the number of activities attended and then displays the corresponding membership fee.

Input Validation: Do not accept a negative value for either the age or the number of activities.

\section*{15. Shipping Charges}

The Fast Freight Shipping Company charges the following rates:
\begin{tabular}{ll}
\hline Weight of Package (in Kilograms) & Rate per 500 Miles Shipped \\
\hline 2 kg or less & \(\$ 1.10\) \\
Over 2 kg but not more than 6 kg & \(\$ 2.20\) \\
Over 6 kg but not more than 10 kg & \(\$ 3.70\) \\
Over 10 kg but not more than 20 kg & \(\$ 4.80\) \\
\hline
\end{tabular}

Write a program that asks for the weight of the package and the distance it is to be shipped, then displays the charges.
Input Validation: Do not accept values of 0 or less for the weight of the package. Do not accept weights of more than 20 kg (this is the maximum weight the company will ship). Do not accept distances of less than 10 miles or more than 3,000 miles. These are the company's minimum and maximum shipping distances.

\section*{16. Negative Split}

Running the second half of a race faster than the first half is called a negative split. Write a program that asks for the time (in seconds) for the first half of a race and for the total of the race, and outputs a congratulatory message in case of a negative split. Input Validation: Do not accept negative values for either time. Also check that the second time is greater than the first time.

\section*{17. Toss of a Coin}

Write a program that simulates the toss of a coin. The program asks the user to input either H (for head) or T (for tail). It then randomly generates either H (internally represented by 1 ) or T (internally represented by 0 ). If the user's prediction matches with the generated toss, display "Won"; otherwise display "Lost".

\section*{18. Fat Gram Calculator}

Write a program that asks for the number of calories and fat grams in a food. The program should display the percentage of calories that come from fat. If the calories from fat are less than 30 percent of the total calories of the food, it should also display a message indicating that the food is low in fat.
One gram of fat has 9 calories, so
Calories from fat \(=\) fat grams *9
The percentage of calories from fat can be calculated as
Calories from fat \(\div\) total calories
Input Validation: Make sure the number of calories and fat grams are not less than 0. Also, the number of calories from fat cannot be greater than the total number of calories. If that happens, display an error message indicating that either the calories or fat grams were incorrectly entered.

\section*{19. Spectral Analysis}

If a scientist knows the wavelength of an electromagnetic wave, he or she can determine what type of radiation it is. Write a program that asks for the wavelength of an electromagnetic wave in meters and then displays what that wave is according to the chart below. (For example, a wave with a wavelength of \(1 \mathrm{E}-10\) meters would be an X-ray.)

20. The Speed of Sound

The following table shows the approximate speed of sound in air, water, and steel.
\begin{tabular}{ll}
\hline Medium & Speed \\
\hline Air & 1,100 feet per second \\
Water & 4,900 feet per second \\
Steel & 16,400 feet per second \\
\hline
\end{tabular}

Write a program that displays a menu allowing the user to select air, water, or steel. After the user has made a selection, he or she should be asked to enter the distance a sound wave will travel in the selected medium. The program will then display the amount of time it will take. (Round the answer to four decimal places.)
Input Validation: Check that the user has selected one of the available choices from the menu. Do not accept distances less than 0 .

\section*{21. The Speed of Sound in Gases}

When sound travels through a gas, its speed depends primarily on the density of the medium. The less dense the medium, the faster the speed will be. The following table shows the approximate speed of sound at 0 degrees centigrade, measured in meters per second, when traveling through carbon dioxide, air, helium, and hydrogen.
\begin{tabular}{ll}
\hline Medium & Speed (Meters per Second) \\
\hline Carbon dioxide & 258.0 \\
Air & 331.5 \\
Helium & 972.0 \\
Hydrogen & \(1,270.0\) \\
\hline
\end{tabular}

Write a program that displays a menu allowing the user to select one of these four gases. After a selection has been made, the user should enter the number of seconds it took for the sound to travel in this medium from its source to the location at which it was detected. The program should then report how far away (in meters) the source of the sound was from the detection location.
Input Validation: Check that the user has selected one of the available menu choices. Do not accept times less than 0 seconds or more than 30 seconds.

\section*{22. Freezing and Boiling Points}

The following table lists the freezing and boiling points of several substances. Write a program that asks the user to enter a temperature then shows all the substances that will freeze at that temperature, and all that will boil at that temperature. For example, if the user enters -20 , the program should report that water will freeze and oxygen will boil at that temperature.
\begin{tabular}{llc}
\hline Substance & Freezing Point \(\left({ }^{\circ} \mathrm{F}\right)\) & Boiling Point \(\left({ }^{\circ} \mathrm{F}\right)\) \\
\hline Ethyl alcohol & -173 & 172 \\
Mercury & -38 & 676 \\
Oxygen & -362 & -306 \\
Water & 32 & 212 \\
\hline
\end{tabular}

\section*{23. Guessing Games}

Write a program that displays the following menu:

\section*{Guessing games}
1. Play Higher or Lower
2. Play paper-scissors-rock
3. Guess the number of fingers
4. Quit

Enter your choice (1-4):
If the user enters 1 , the program should generate two random numbers between 1 and 20 and display the first number. It should then ask the user to enter either H or L for Higher or Lower. The user wins if they entered H and the second number was higher than the first or when they entered L and the second number was lower.
If the user enters 2 , the program should generate one random number between 1 and 3 with 1 corresponding to paper, 2 to scissors, and 3 to rock. The program should then ask the user to enter P for paper, S for scissors, or R for rock. The program should then display who won: the computer or the user. Scissors beats paper, rock beats scissors, and paper beats rock.
Finally, if the user enters 3, the program should generate a random number between 1 and 5 . The user can enter a number in the same range, and they win when their guess is correct.

Input Validation: Display an error message if the user enters a number outside the range of 1 through 4 when selecting an item from the menu. Do not accept characters other than H or L for Higher/Lower, other than P, S, and R for paper-scissors-rock, or a value outside the range from 1 to 5 for guessing fingers.

\section*{24. Parking Lot}

A parking lot charges the following rates for parking:
\begin{tabular}{ll}
\hline Number of Hours & Rate per Hour \\
\hline\(\leq 2\) & \(\$ 2\) \\
Over 2 but not more than 4 & \(\$ 1.75\) \\
\(\geq 5\) & \(\$ 1.50\) \\
\hline
\end{tabular}

Write a program that asks for the starting and ending times of a parked car and displays the amount to be paid. The program should ask for the times to be entered as floating-point numbers in the form HH.MM. For example, 07:00 hours will be entered as 07.00 , and \(16: 28\) hours will be entered as 16.28 .
Note that each initiated hour must be paid in full. For example, 1 hour and 3 minutes will cost \$4.
Input Validation: The program should not accept times that are greater than 21:59 or less than 07:00, the operating hours of the parking lot. Also, no number whose last two digits are greater than 59 should be accepted.
Hint: You can get the minutes of the time by multiplying the time by 100 and then taking the remainder of the division by 100 .

\section*{25. Tourist Attraction}

A tourist attraction offers three types of tickets:
- Regular adult tickets at \(\$ 30\) per person, with a reduction of \(10 \%\) for groups of at least five persons.
- Student tickets at \(\$ 25\) per person
- Family tickets for two adults and two or more children. The price is \(\$ 75\), with an additional \(\$ 15\) for each child beyond two children.
Write a program that calculates the total price of tickets. The program displays a menu with the three options, lets the user select an option, and then asks for the number of people in the party. It should then display the total amount due.
Input Validation: Make sure the user cannot select invalid options in the menu and that the number of people in the party is always greater than 0 .

\section*{26. Tourist Attraction, Part 2}

Extend the previous solution by showing at the end of the program how much money was saved compared to a regular adult ticket. If there are no savings, no message should be shown. Also print out an advertisement for a "Come back" ticket at \$10 each and include the total amount in the message.

\section*{27. Wi-Fi Diagnostic Tree}

Figure 4-11 shows a simplified flowchart for troubleshooting a bad Wi-Fi connection. Use the flowchart to create a program that leads a person through the steps of fixing a bad Wi-Fi connection. Here is an example of the program's output:
```

Reboot the computer and try to connect.
Did that fix the problem? no Enter
Reboot the router and try to connect.
Did that fix the problem? yes Enter

```

Notice the program ends as soon as a solution is found to the problem. Here is another example of the program's output:
```

Reboot the computer and try to connect.
Did that fix the problem? no Enter
Reboot the router and try to connect.
Did that fix the problem? no Enter
Make sure the cables between the router and modem are plugged in firm7y.
Did that fix the problem? no Enter
Move the router to a new location.
Did that fix the problem? no Enter
Get a new router.

```

Figure 4-11 Troubleshooting a bad Wi-Fi connection

\section*{28. Exercise Generator}

Write a program that generates a math exercise for the user.
The program should first ask for which operation an exercise should be generated. The possibilities are addition ( + ), subtraction ( - ), multiplication (*), and division ( \(/\) ).
After selecting an operation, the user should answer the following question:
What is the maximum value for the input values of the exercise?
The answer to this question must be stored in a variable maximumValue.
Next, the program should ask
Are negative values allowed in the exercise?
The possible answers for the question are "Y" and "N".
The program will then generate two random numbers. If the user allows negative values, the random numbers must be generated in the range from -maximumValue to +maximumValue; if the user allows only positive values, the range is restricted from 0 to maximumValue. Moreover, if only positive numbers are allowed and subtraction was chosen, the second random value must be less than the first random value.

Finally, the program will show the generated exercise, depending on the chosen operation and the numbers randomly generated, and ask the user for the correct solution. If the user solves the exercise correctly, the program will print out a congratulatory message.

\section*{\(\square \square \square \square \square\)}

\subsection*{5.1 The Increment and Decrement Operators}

CONCEPT: ++ and -- are operators that add and subtract 1 from their operands.

To increment a value means to increase it by one, and to decrement a value means to decrease it by one. Both of the following statements increment the variable num:
```

num = num + 1;
num += 1;

```

And num is decremented in both of the following statements:
```

num = num - 1;
num -= 1;

```

C++ provides a set of simple unary operators designed just for incrementing and decrementing variables. The increment operator is ++, and the decrement operator is --. The following statement uses the ++ operator to increment num:
```

num++;

```

And the following statement decrements num:
num--;

NOTE: The expression num++ is pronounced "num plus plus," and num-- is pronounced "num minus minus."

Our examples so far show the increment and decrement operators used in postfix mode, which means the operator is placed after the variable. The operators also work in prefix mode, where the operator is placed before the variable name:
```

++num;
--num;

```

In both postfix and prefix modes, these operators add 1 to or subtract 1 from their operand. Program 5-1 shows how they work.

\section*{Program 5-1}
```

// This program demonstrates the ++ and -- operators.
\#include <iostream>
using namespace std;
int main()
{
int num = 4; // num starts out with 4.
// Display the value in num.
cout << "The variable num is " << num << endl;
cout << "I will now increment num.\n\n";
// Use postfix ++ to increment num.
num++;
cout << "Now the variable num is " << num << endl;
cout << "I will increment num again.\n\n";
// Use prefix ++ to increment num.
++num;
cout << "Now the variable num is " << num << endl;
cout << "I will now decrement num.\n\n";
// Use postfix -- to decrement num.
num--;
cout << "Now the variable num is " << num << endl;
cout << "I will decrement num again.\n\n";
// Use prefix -- to increment num.
--num;
cout << "Now the variable num is " << num << endl;
return 0;
}

```

\section*{Program Output}

The variable num is 4
I will now increment num.
```

Now the variable num is 5
I will increment num again.
Now the variable num is 6
I will now decrement num.
Now the variable num is 5
I will decrement num again.
Now the variable num is 4

```

\section*{The Difference between Postfix and Prefix Modes}

In the simple statements used in Program 5-1, it doesn't matter if the increment or decrement operator is used in postfix or prefix mode. The difference is important, however, when these operators are used in statements that do more than just incrementing or decrementing. For example, look at the following statements:
```

num = 4;
cout << num++;

```

This cout statement is doing two things: (1) displaying the value of num, and (2) incrementing num. But which happens first? cout will display a different value if num is incremented first than if num is incremented last. The answer depends on the mode of the increment operator.

Postfix mode causes the increment to happen after the value of the variable is used in the expression. In the example, cout will display 4, then num will be incremented to 5. Prefix mode, however, causes the increment to happen first. In the following statements, num will be incremented to 5 , then cout will display 5 :
```

num = 4;
cout << ++num;

```

Program 5-2 illustrates these dynamics further.

\section*{Program 5-2}
```

// This program demonstrates the prefix and postfix
// modes of the increment and decrement operators.
\#include <iostream>
using namespace std;
int main()
{
int num = 4;
cout << num << endl; // Displays 4
cout << num++ << endl; // Displays 4, then adds 1 to num
cout << num << endl; // Displays 5
cout << ++num << endl; // Adds 1 to num, then displays 6
cout << endl; // Displays a blank line

```

\section*{Program 5-2}
(continued)
```

16 cout << num << endl; // Displays 6
17 cout << num-- << endl; // Displays 6,
18
1 9
20
21 return 0;
22 }

```

\section*{Program Output}

4
4
5
6
6
6
5
4

Let's analyze the statements in this program. In line 8 , num is initialized with the value 4 , so the cout statement in line 10 displays 4 . Then, line 11 sends the expression num++ to cout. Because the ++ operator is used in postfix mode, the value 4 is first sent to cout, and then 1 is added to num, making its value 5 .

When line 12 executes, num will hold the value 5 , so 5 is displayed. Then, line 13 sends the expression ++num to cout. Because the ++ operator is used in prefix mode, 1 is first added to num (making it 6), and then the value 6 is sent to cout. This same sequence of events happens in lines 16 through 19 , except the - - operator is used.
For another example, look at the following code:
```

int x = 1;
int y
y = x++; // Postfix increment

```

The first statement defines the variable x (initialized with the value 1 ), and the second statement defines the variable y . The third statement does two things:
- It assigns the value of \(x\) to the variable \(y\).
- The variable x is incremented.

The value that will be stored in \(y\) depends on when the increment takes place. Because the ++ operator is used in postfix mode, it acts after the assignment takes place. So, this code will store 1 in y . After the code has executed, x will contain 2 . Let's look at the same code, but with the ++ operator used in prefix mode:
```

int x = 1;
int y;
y = ++x; // Prefix increment

```

In the third statement, the ++ operator is used in prefix mode, so it acts on the variable \(x\) before the assignment takes place. So, this code will store 2 in \(y\). After the code has executed, \(x\) will also contain 2.

\section*{Using ++ and -- in Mathematical Expressions}

The increment and decrement operators can also be used on variables in mathematical expressions. Consider the following program segment:
```

a = 2;
b = 5;
c = a * b++;
cout << a << " " << b << " " << c;

```

In the statement \(c=a * b++, c\) is assigned the value of a times \(b\), which is 10 . The variable \(b\) is then incremented. The cout statement will display

2610
If the statement were changed to read
```

c = a * ++b;

```
the variable \(b\) would be incremented before it was multiplied by a. In this case, \(c\) would be assigned the value of 2 times 6 , so the cout statement would display
```

2 12

```

You can pack a lot of action into a single statement using the increment and decrement operators, but don't get too tricky with them. You might be tempted to try something like the following, thinking that c will be assigned 11:
```

a = 2;
b = 5;
c = ++(a * b); // Error!

```

But this assignment statement simply will not work because the operand of the increment and decrement operators must be an lvalue. Recall from Chapter 2 that an lvalue identifies a place in memory whose contents may be changed. The increment and decrement operators usually have variables for their operands, but generally speaking, anything that can go on the left side of an = operator is legal.

\section*{Using ++ and -- in Relational Expressions}

Sometimes you will see code where the ++ and -- operators are used in relational expressions. Just as in mathematical expressions, the difference between postfix and prefix modes is critical. Consider the following program segment:
```

x = 10;
if (x++ > 10)
cout << "x is greater than 10.\n";

```

Two operations are happening in this if statement: (1) The value in \(x\) is tested to determine if it is greater than 10 , and (2) \(x\) is incremented. Because the increment operator is used in postfix mode, the comparison happens first. Since 10 is not greater than 10 , the cout
statement won't execute. If the mode of the increment operator is changed, however, the if statement will compare 11 to 10 , and the cout statement will execute:
```

x = 10;
if (++x > 10)
cout << "x is greater than 10.\n";

```

\section*{Checkpoint}
5.1 What will the following program segments display?
A) \(x=2\);
\(y=x++;\)
cout << x << y;
B) \(x=2\);
\(y=++x ;\)
cout << \(x \ll y\);
C) \(x=2\);
\(y=4 ;\)
cout << x++ << --y;
D) \(x=2\);
\(y=2\) * \(x++;\)
cout \(\ll x \ll y\);
E) \(\mathrm{x}=99\);
if ( \(\mathrm{x}++\) < 100) cout "It is true! 1 n ";
else
cout << "It is false! 1 n ";
F) \(x=0\);
if (++x)
cout << "It is true!\n";
else
cout << "It is false!\n";

\subsection*{5.2 Introduction to Loops: The white Loop}

CONCEPT: A loop is part of a program that repeats.
Chapter 4 introduced the concept of control structures, which direct the flow of a program. A loop is a control structure that causes a statement or group of statements to repeat. C++ has three looping control structures: the while loop, the do-while loop, and the for loop. The difference between these structures is how they control the repetition.

\section*{The while Loop}

The while loop has two important parts: (1) an expression that is tested for a true or false value, and (2) a statement or block that is repeated as long as the expression is true. Figure 5-1 shows the logic of a while loop.

Figure 5-1 Logic of a while loop

Here is the general format of the while loop:
```

while (expression)
statement;

```

In the general format, expression is any expression that can be evaluated as true or false, and statement is any valid \(\mathrm{C}++\) statement. The first line shown in the format is sometimes called the loop header. It consists of the key word while followed by an expression enclosed in parentheses.

Here's how the loop works: the expression is tested, and if it is true, the statement is executed. Then, the expression is tested again. If it is true, the statement is executed. This cycle repeats until the expression is false.

The statement that is repeated is known as the body of the loop. It is also considered a conditionally executed statement, because it is executed only under the condition that the expression is true.

Notice there is no semicolon after the expression in parentheses. Like the if statement, the while loop is not complete without the statement that follows it.

If you wish the while loop to repeat a block of statements, its format is:
```

while (expression)
{
statement;
statement;
// Place as many statements here
// as necessary.
}

```

The while loop works like an if statement that executes over and over. As long as the expression inside the parentheses is true, the conditionally executed statement or block will repeat. Program 5-3 uses the while loop to print "Hello" five times.

\section*{Program 5-3}
```

// This program demonstrates a simple while loop.
\#include <iostream>
using namespace std;
int main()
{
int number = 0;
while (number < 5)
{
cout << "Hello\n";
number++;
}
cout << "That's al1!\n";
return 0;
}

```

\section*{Program Output}

Hello
Hello
Hello
Hello
Hello
That's all!

Let's take a closer look at this program. In line 7, an integer variable, number, is defined and initialized with the value 0 . In line 9 , the while loop begins with this statement:
```

while (number < 5)

```

This statement tests the variable number to determine whether it is less than 5 . If it is, then the statements in the body of the loop (lines 11 and 12) are executed:
```

cout << "Hello\n";
number++;

```

The statement in line 11 prints the word "Hello." The statement in line 12 uses the increment operator to add one to number. This is the last statement in the body of the loop, so after it executes, the loop starts over. It tests the expression number \(<5\) again, and if it is true, the statements in the body of the loop are executed again. This cycle repeats until the expression number \(<5\) is false. This is illustrated in Figure 5-2.

Each repetition of a loop is known as an iteration. This loop will perform five iterations because the variable number is initialized with the value 0 , and it is incremented each time the body of the loop is executed. When the expression number \(<5\) is tested and found to be false, the loop will terminate and the program will resume execution at the statement that immediately follows the loop. Figure 5-3 shows the logic of this loop.

Figure 5-2 Actions of the while loop

Figure 5-3 Flowchart for the while loop

In this example, the number variable is referred to as the loop control variable because it controls the number of times that the loop iterates.

\section*{The while Loop Is a Pretest Loop}

The while loop is known as a pretest loop, which means it tests its expression before each iteration. Notice the variable definition in line 7 of Program 5-3:
```

int number = 0;

```

The number variable is initialized with the value 0 . If number had been initialized with the value 5 or greater, as shown in the following program segment, the loop would never execute:
```

int number = 6;
while (number < 5)
{
cout << "Hello\n";
number++;
}

```

An important characteristic of the while loop is that the loop will never iterate if the test expression is false to start with. If you want to be sure that a while loop executes the first time, you must initialize the relevant data in such a way that the test expression starts out as true.

\section*{Infinite Loops}

In all but rare cases, loops must contain within themselves a way to terminate. This means that something inside the loop must eventually make the test expression false. The loop in Program 5-3 stops when the expression number \(<5\) is false.

If a loop does not have a way of stopping, it is called an infinite loop. An infinite loop continues to repeat until the program is interrupted. Here is an example of an infinite loop:
```

int number = 0;
while (number < 5)
{
cout << "Hello\n";
}

```

This is an infinite loop because it does not contain a statement that changes the value of the number variable. Each time the expression number < 5 is tested, number will contain the value 0 .

It's also possible to create an infinite loop by accidentally placing a semicolon after the first line of the while loop. Here is an example:
```

int number = 0;
while (number < 5); // This semicolon is an ERROR!
{
cout << "Hello\n";
number++;
}

```

The semicolon at the end of the first line is assumed to be a null statement and disconnects the while statement from the block that comes after it. To the compiler, this loop looks like:
```

while (number < 5);

```

This while loop will forever execute the null statement, which does nothing. The program will appear to have "gone into space" because there is nothing to display screen output or show activity.

\section*{Don't Forget the Braces with a Block of Statements}

If you write a loop that conditionally executes a block of statements, don't forget to enclose all of the statements in a set of braces. If the braces are accidentally left out, the while statement conditionally executes only the very next statement. For example, look at the following code:
```

int number = 0;
// This loop is missing its braces!
while (number < 5)
cout << "Hello\n";
number++;

```

In this code, the number++ statement is not in the body of the loop. Because the braces are missing, the while statement only executes the statement that immediately follows it. This loop will execute infinitely because there is no code in its body that changes the number variable.

Another common pitfall with loops is accidentally using the = operator when you intend to use the \(==\) operator. The following is an infinite loop because the test expression assigns 1 to remainder each time it is evaluated instead of testing whether remainder is equal to 1 :
```

while (remainder = 1) // Error: Notice the assignment
{
cout << "Enter a number: ";
cin >> num;
remainder = num % 2;
}

```

Remember, any nonzero value is evaluated as true.

\section*{Programming Style and the while Loop}

It's possible to create loops that look like this:
```

while (number < 5) { cout << "Hello\n"; number++; }

```

Avoid this style of programming. The programming style you should use with the while loop is similar to that of the if statement:
- If there is only one statement repeated by the loop, it should appear on the line after the while statement and be indented one additional level.
- If the loop repeats a block, each line inside the braces should be indented.

This programming style should visually set the body of the loop apart from the surrounding code. In general, you'll find a similar style being used with the other types of loops presented in this chapter.

\section*{In the Spotlight:}

\section*{Designing a Program with a while Loop}

A project currently underway at Chemical Labs, Inc. requires that a substance be continually heated in a vat. A technician must check the substance's temperature every 15 minutes. If the substance's temperature does not exceed 102.5 degrees Celsius, then the technician does nothing. However, if the temperature is greater than 102.5 degrees Celsius, the technician must turn down the vat's thermostat, wait 5 minutes, and check the temperature again. The technician repeats these steps until the temperature does not exceed 102.5 degrees Celsius. The director of engineering has asked you to write a program that guides the technician through this process.

Here is the algorithm:
1. Prompt the user to enter the substance's temperature.
2. Repeat the following steps as long as the temperature is greater than 102.5 degrees Celsius:
a. Tell the technician to turn down the thermostat, wait 5 minutes, and check the temperature again.
b. Prompt the user to enter the substance's temperature.
3. After the loop finishes, tell the technician that the temperature is acceptable and to check it again in 15 minutes.

After reviewing this algorithm, you realize that steps \(2 a\) and \(2 b\) should not be performed if the test condition (temperature is greater than 102.5) is false to begin with. The while loop will work well in this situation, because it will not execute even once if its condition is false. Program 5-4 shows the code for the program.

\section*{Program 5-4}
```

// This program assists a technician in the process
// of checking a substance's temperature.
\#include <iostream>
using namespace std;
int main()
{
const double MAX_TEMP = 102.5; // Maximum temperature
double temperature; // To hold the temperature
// Get the current temperature.
cout << "Enter the substance's Celsius temperature: ";
cin >> temperature;
// As long as necessary, instruct the technician
// to adjust the thermostat.
while (temperature > MAX_TEMP)
{
cout << "The temperature is too high. Turn the\n";
cout << "thermostat down and wait 5 minutes.\n";
cout << "Then take the Celsius temperature again\n";
cout << "and enter it here: ";
cin >> temperature;
}
// Remind the technician to check the temperature
// again in 15 minutes.
cout << "The temperature is acceptable.\n";
cout << "Check it again in 15 minutes.\n";
return 0;
}

```

\section*{Program Output with Example Input Shown in Bold}

Enter the substance's Celsius temperature: 104.7 Enter
The temperature is too high. Turn the thermostat down and wait 5 minutes.
Then take the Celsius temperature again
and enter it here: 103.2 Enter
The temperature is too high. Turn the thermostat down and wait 5 minutes.
Then take the Celsius temperature again
and enter it here: \(\mathbf{1 0 2 . 1}\) Enter
The temperature is acceptable.
Check it again in 15 minutes.

\subsection*{5.3 Using the while Loop for Input Validation \\ CONCEPT: The while loop can be used to create input routines that repeat until acceptable data is entered.}

Perhaps the most famous saying of the computer industry is "garbage in, garbage out." The integrity of a program's output is only as good as its input, so you should try to make sure garbage does not go into your programs. Input validation is the process of inspecting data given to a program by the user and determining if it is valid. A good program should give clear instructions about the kind of input that is acceptable, and not assume the user has followed those instructions.

The while loop is especially useful for validating input. If an invalid value is entered, a loop can require that the user reenter it as many times as necessary. For example, the following loop asks for a number in the range of 1 through 100:
```

cout << "Enter a number in the range 1-100: ";
cin >> number;
while (number < 1 || number > 100)
{
cout << "ERROR: Enter a value in the range 1-100: ";
cin >> number;
}

```

This code first allows the user to enter a number. This takes place just before the loop. If the input is valid, the loop will not execute. If the input is invalid, however, the loop will display an error message and require the user to enter another number. The loop will continue to execute until the user enters a valid number. The general logic of performing input validation is shown in Figure 5-4.

Figure 5-4 Flowchart for input validation

The read operation that takes place just before the loop is called a priming read. It provides the first value for the loop to test. Subsequent values are obtained by the loop.

Program 5-5 calculates the number of soccer teams a youth league may create, based on a given number of players and a maximum number of players per team. The program uses while loops (in lines 25 through 34 and lines 41 through 46) to validate the user's input.

\section*{Program 5-5}
46
```

// This program calculates the number of soccer teams

```
// This program calculates the number of soccer teams
// that a youth league may create from the number of
// that a youth league may create from the number of
// available players. Input validation is demonstrated
// available players. Input validation is demonstrated
// with while loops.
// with while loops.
#include <iostream>
#include <iostream>
using namespace std;
using namespace std;
int main()
int main()
{
{
    // Constants for minimum and maximum players
    // Constants for minimum and maximum players
    const int MIN_PLAYERS = 9,
    const int MIN_PLAYERS = 9,
            MAX_PLAYERS = 15;
            MAX_PLAYERS = 15;
    // Variables
    // Variables
    int players, // Number of available players
    int players, // Number of available players
        teamPlayers, // Number of desired players per team
        teamPlayers, // Number of desired players per team
        numTeams, // Number of teams
        numTeams, // Number of teams
        leftOver; // Number of players left over
        leftOver; // Number of players left over
    // Get the number of players per team.
    // Get the number of players per team.
    cout << "How many players do you wish per team? ";
    cout << "How many players do you wish per team? ";
    cin >> teamPlayers;
    cin >> teamPlayers;
    // Validate the input.
    // Validate the input.
    while (teamPlayers < MIN_PLAYERS || teamPlayers > MAX_PLAYERS)
    while (teamPlayers < MIN_PLAYERS || teamPlayers > MAX_PLAYERS)
    {
    {
        // Explain the error.
        // Explain the error.
        cout << "You should have at least " << MIN_PLAYERS
        cout << "You should have at least " << MIN_PLAYERS
            << " but no more than " << MAX_PLAYERS << " per team.\n";
            << " but no more than " << MAX_PLAYERS << " per team.\n";
        // Get the input again.
        // Get the input again.
        cout << "How many players do you wish per team? ";
        cout << "How many players do you wish per team? ";
        cin >> teamPlayers;
        cin >> teamPlayers;
    }
    }
    // Get the number of players available.
    // Get the number of players available.
    cout << "How many players are available? ";
    cout << "How many players are available? ";
    cin >> players;
    cin >> players;
    // Validate the input.
    // Validate the input.
    while (players <= 0)
    while (players <= 0)
    {
    {
        // Get the input again.
        // Get the input again.
        cout << "Please enter 0 or greater: ";
        cout << "Please enter 0 or greater: ";
        cin >> players;
        cin >> players;
    }
```

    }
    ```
```

    // Calculate the number of teams.
    numTeams = players / teamPlayers;
    // Calculate the number of leftover players.
    leftOver = players % teamPlayers;
    // Display the results.
    cout << "There will be " << numTeams << " teams with "
        << leftOver << " players left over.\n";
        return 0;
    }

```

\section*{Program Output with Example Input Shown in Bold}

How many players do you wish per team? 4 Enter
You should have at least 9 but no more than 15 per team.
How many players do you wish per team? 12 Enter
How many players are available? -142 Enter
Please enter 0 or greater: 142 Enter
There will be 11 teams with 10 players left over.

\section*{Checkpoint}
5.2 Write an input validation loop that asks the user to enter a number in the range of 10 through 25.
5.3 Write an input validation loop that asks the user to enter ' Y ', ' y ', ' N ', or ' n '.
5.4 Write an input validation loop that asks the user to enter "Yes" or "No".

\subsection*{5.4 Counters}

CONCEPT: A counter is a variable that is regularly incremented or decremented each time a loop iterates.

Sometimes it's important for a program to control or keep track of the number of iterations a loop performs. For example, Program 5-6 displays a table consisting of the numbers 1 through 10 and their squares, so its loop must iterate 10 times.

\section*{Program 5-6}
```

// This program displays a list of numbers and
// their squares.
\#include <iostream>
using namespace std;
int main()
{
const int MIN_NUMBER = 1, // Starting number to square
MAX_NUMBER = 10; // Maximum number to square

```

\section*{Program 5-6}
(continued)
```

    int num = MIN_NUMBER; // Counter
    cout << "Number Number Squared\n";
    cout << "------------------------\n";
    while (num <= MAX_NUMBER)
    {
        cout << num << "\t\t" << (num * num) << endl;
        num++; //Increment the counter.
        }
        return 0;
    }
    ```

\section*{Program Output}

Number Number Squared
\begin{tabular}{ll}
------------- \\
1 & 1 \\
2 & 4 \\
3 & 9 \\
4 & 16 \\
5 & 25 \\
6 & 36 \\
7 & 49 \\
8 & 64 \\
9 & 81 \\
10 & 100
\end{tabular}

In Program 5-6, the variable num, which starts at 1 , is incremented each time through the loop. When num reaches 11 , the loop stops. num is used as a counter variable, which means it is regularly incremented in each iteration of the loop. In essence, num keeps count of the number of iterations the loop has performed.

NOTE: It's important that num be properly initialized. Remember, variables defined inside a function have no guaranteed starting value.

\subsection*{5.5 The do-while Loop}

CONCEPT: The do-while loop is a posttest loop, which means its expression is tested after each iteration.

The do-while loop looks something like an inverted while loop. Here is the do-while loop's format when the body of the loop contains only a single statement:
```

do
statement;
while (expression);

```

Here is the format of the do-while loop when the body of the loop contains multiple statements:
```

do
{
statement;
statement;
// Place as many statements here
// as necessary.
} while (expression);

```

NOTE: The do-while loop must be terminated with a semicolon.

The do-while loop is a posttest loop. This means it does not test its expression until it has completed an iteration. As a result, the do-while loop always performs at least one iteration, even if the expression is false to begin with. This differs from the behavior of a while loop, which you will recall is a pretest loop. For example, in the following while loop the cout statement will not execute at all:
```

int x = 1;
while (x < 0)
cout << x << endl;

```

But the cout statement in the following do-while loop will execute once because the do-while loop does not evaluate the expression \(\mathrm{x}<0\) until the end of the iteration.
```

int x = 1;
do
cout << x << endl;
while (x < 0);

```

Figure 5-5 illustrates the logic of the do-while loop.
Figure 5-5 Flowchart for a do-while loop

You should use the do-while loop when you want to make sure the loop executes at least once. For example, Program 5-7 averages a series of three test scores for a student.

After the average is displayed, it asks the user if he or she wants to average another set of test scores. The program repeats as long as the user enters Y for yes.

\section*{Program 5-7}
```

// This program averages 3 test scores. It repeats as
// many times as the user wishes.
\#include <iostream>
using namespace std;
int main()
{
int score1, score2, score3; // Three scores
double average; // Average score
char again; // To hold Y or N input
do
{
// Get three scores.
cout << "Enter 3 scores and I wil1 average them: ";
cin >> score1 >> score2 >> score3;
// Calculate and display the average.
average = (score1 + score2 + score3) / 3.0;
cout << "The average is " << average << ".\n";
// Does the user want to average another set?
cout << "Do you want to average another set? (Y/N) ";
cin >> again;
} while (again == 'Y' || again == 'y');
return 0;
}

```
```

Program Output with Example Input Shown in Bold
Enter 3 scores and I will average them: 8099070 Enter
The average is 80.
Do you want to average another set? (Y/N) y Enter
Enter 3 scores and I wil1 average them: 60 75 88 Enter
The average is 74.3333.
Do you want to average another set? (Y/N) n Enter

```

When this program was written, the programmer had no way of knowing the number of times the loop would iterate. This is because the loop asks the user if he or she wants to repeat the process. This type of loop is known as a user-controlled loop, because it allows the user to decide the number of iterations.

\section*{Using do-while with Menus}

The do-while loop is a good choice for repeating a menu. Recall Program 4-27, which displayed a menu of health club packages. Program 5-8 is a modification of that program, which uses a do-while loop to repeat the program until the user selects item 4 from the menu.

\section*{Program 5-8}
// This program displays a menu and asks the user to make a
// selection. A do-while loop repeats the program until the
// user selects item 4 from the menu.
\#include <iostream>
\#include <iomanip>
using namespace std;
int main()
\{
    // Constants for menu choices
    const int ADULT_CHOICE = 1,
        CHILD_CHOICE = 2,
        SENIOR_CHOICE = 3,
        QUIT_CHOICE = 4;
    // Constants for membership rates
    const double ADULT = 40.0,
                                    CHILD = 20.0,
                                    SENIOR = 30.0;
    // Variables
    int choice; // Menu choice
    int months; // Number of months
    double charges; // Monthly charges
    // Set up numeric output formatting.
    cout << fixed << showpoint << setprecision(2);
    do
    \{
        // Display the menu.
        cout << "\n\t\tHealth Club Membership Menu\n\n"
                        \(\ll\) "1. Standard Adult Membership\n"
            << "2. Child Membership\n"
            << "3. Senior Citizen Membership\n"
            << "4. Quit the Program\n\n"
            << "Enter your choice: ";
                cin >> choice;
                // Validate the menu selection.
                while (choice < ADULT_CHOICE || choice > QUIT_CHOICE)
                \{
            cout << "Please enter a valid menu choice: ";
            cin >> choice;
        \}
        // Process the user's choice.
        if (choice != QUIT_CHOICE)
        \{
            // Get the number of months.
        cout << "For how many months? ";

\section*{Checkpoint}
5.5 What will the following program segments display?
A) int count \(=10\);
do
\{
cout << "Hello World\n"; count++;
\} while (count < 1);
```

B) int v = 10;
do
cout << v << end1;
while (v < 5);
C) int count = 0, number = 0, limit = 4;
do
{
number += 2;
count++;
} while (count < limit);
cout << number << " " << count << endl;

```

\subsection*{5.6 The for Loop}

CONCEPT: The for loop is ideal for performing a known number of iterations.
In general, there are two categories of loops: conditional loops and count-controlled loops. A conditional loop executes as long as a particular condition exists. For example, an input validation loop executes as long as the input value is invalid. When you write a conditional loop, you have no way of knowing the number of times it will iterate.

Sometimes you know the exact number of iterations that a loop must perform. A loop that repeats a specific number of times is known as a count-controlled loop. For example, if a loop asks the user to enter the sales amounts for each month in the year, it will iterate 12 times. In essence, the loop counts to 12 and asks the user to enter a sales amount each time it makes a count. A count-controlled loop must possess three elements:
1. It must initialize a counter variable to a starting value.
2. It must test the counter variable by comparing it to a maximum value. When the counter variable reaches its maximum value, the loop terminates.
3. It must update the counter variable during each iteration. This is usually done by incrementing the variable.

Count-controlled loops are so common that C++ provides a type of loop specifically for them. It is known as the for loop. The for loop is specifically designed to initialize, test, and update a counter variable. Here is the format of the for loop when it is used to repeat a single statement:
```

for (initialization; test; update)
statement;

```

The format of the for loop when it is used to repeat a block is
```

for (initialization; test; update)
{
statement;
statement;
// Place as many statements here
// as necessary.
}

```

The first line of the for loop is the loop header. After the key word for, there are three expressions inside the parentheses, separated by semicolons. (Notice there is not a semicolon after the third expression.) The first expression is the initialization expression. It is normally used to initialize a counter variable to its starting value. This is the first action performed by the loop, and it is only done once. The second expression is the test expression. This is an expression that controls the execution of the loop. As long as this expression is true, the body of the for loop will repeat. The for loop is a pretest loop, so it evaluates the test expression before each iteration. The third expression is the update expression. It executes at the end of each iteration. Typically, this is a statement that increments the loop's counter variable.

Here is an example of a simple for loop that prints "Hello" five times:
```

for (count = 0; count < 5; count++)
cout << "Hello" << endl;

```

In this loop, the initialization expression is count \(=0\), the test expression is count \(<5\), and the update expression is count++. The body of the loop has one statement, which is the cout statement. Figure 5-6 illustrates the sequence of events that takes place during the loop's execution. Notice Steps 2 through 4 are repeated as long as the test expression is true.

Figure 5-6 Sequence of events in a for loop
Step 1: Perform the initialization expression.

Step 4: Perform the update expression, then go back to Step 2.

Figure 5-7 shows the loop's logic in the form of a flowchart.
Figure 5-7 for loop logic

Notice how the counter variable, count, is used to control the number of times that the loop iterates. During the execution of the loop, this variable takes on the values 1 through 5 , and when the test expression count < 5 is false, the loop terminates. Also notice in this example the count variable is used only in the loop header, to control the number of loop iterations. It is not used for any other purpose. It is also possible to use the counter variable within the body of the loop. For example, look at the following code:
```

for (number = 1; number <= 10; number++)
cout << number << " " << endl;

```

The counter variable in this loop is number. In addition to controlling the number of iterations, it is also used in the body of the loop. This loop will produce the following output:
```

1 2 3 4 5 6 7 8 9 10

```

As you can see, the loop displays the contents of the number variable during each iteration. Program 5-9 shows another example of a for loop that uses its counter variable within the body of the loop. This is yet another program that displays a table showing the numbers 1 through 10 and their squares.

\section*{Program 5-9}
// This program displays the numbers 1 through 10 and
// their squares.
\#include <iostream>
```

using namespace std;

```
int main()
\{
    const int MIN_NUMBER = 1, // Starting value
                                    MAX_NUMBER = 10; // Ending value
    int num;
    cout << "Number Number Squared \(\backslash n\) ";
    cout << "--------------------------|n";
    for (num = MIN_NUMBER; num <= MAX_NUMBER; num++)
        cout \(\ll\) num \(\ll ~ " \backslash t \mid t " ~ \ll ~(n u m ~ * ~ n u m) ~ \ll ~ e n d 1 ; ~\)
    return 0;
\}

\section*{Program Output}
\begin{tabular}{ll} 
Number Number Squared \\
\hline----------------1 \\
1 & 4 \\
2 & 9 \\
3 & 16 \\
4 & 25 \\
5 & 36 \\
6 & 49 \\
7 & 64 \\
8 & 81 \\
9 & 100
\end{tabular}

Figure 5-8 illustrates the sequence of events performed by this for loop, and Figure 5-9 shows the logic of the loop as a flowchart.

\section*{Figure 5-8 Sequence of events in the for loop}

Step 1: Perform the initialization Step 2: Evaluate the test expression. Step 4: Perform the update expression. \(\quad\) If it is true, go to Step 3. expression, then go back to Step 2.

Figure 5-9 Flowchart for the for loop

\section*{Using the for Loop instead of while or do-while}

You should use the for loop instead of the while or do-while loop in any situation that clearly requires an initialization, uses a false condition to stop the loop, and requires an update to occur at the end of each loop iteration. Program 5-9 is a perfect example. It requires that the num variable be initialized to 1 , it stops the loop when num is greater than 10 , and it increments num at the end of each loop iteration.
Recall that when we first introduced the idea of a counter variable we examined Program \(5-6\), which uses a while loop to display the table of numbers and their squares. Because the loop in that program requires an initialization, uses a false test expression to stop, and performs an increment at the end of each iteration, it can easily be converted to a for loop. Figure 5-10 shows how the while loop in Program 5-6 and the for loop in Program 5-9 each have initialization, test, and update expressions.

Figure 5-10 Initialization, test, and update expressions

\section*{The for Loop Is a Pretest Loop}

Because the for loop tests its test expression before it performs an iteration, it is a pretest loop. It is possible to write a for loop in such a way that it will never iterate. Here is an example:
```

for (count = 11; count <= 10; count++)
cout << "Hello" << endl;

```

Because the variable count is initialized to a value that makes the test expression false from the beginning, this loop terminates as soon as it begins.

\section*{Avoid Modifying the Counter Variable in the Body of the for Loop}

Be careful not to place a statement that modifies the counter variable in the body of the for loop. All modifications of the counter variable should take place in the update expression, which is automatically executed at the end of each iteration. If a statement in the body of the loop also modifies the counter variable, the loop will probably not terminate when you expect it to. The following loop, for example, increments x twice for each iteration:
```

for (x = 1; x <= 10; x++)
{
cout << x << endl;
x++; // Wrong!
}

```

\section*{Other Forms of the Update Expression}

You are not limited to using increment statements in the update expression. Here is a loop that displays all the even numbers from 2 through 100 by adding 2 to its counter:
```

for (num = 2; num <= 100; num += 2)
cout << num << endl;

```

And here is a loop that counts backward from 10 down to 0 :
```

for (num = 10; num >= 0; num--)
cout << num << endl;

```

\section*{Defining a Variable in the for Loop's Initialization Expression}

Not only may the counter variable be initialized in the initialization expression, it may be defined there as well. The following code shows an example. This is a modified version of the loop in Program 5-9.
```

for (int num = MIN_NUMBER; num <= MAX_NUMBER; num++)
cout << num << "\t\t" << (num * num) << endl;

```

In this loop, the num variable is both defined and initialized in the initialization expression. If the counter variable is used only in the loop, it makes sense to define it in the loop header. This makes the variable's purpose more clear.

When a variable is defined in the initialization expression of a for loop, the scope of the variable is limited to the loop. This means you cannot access the variable in statements outside the loop. For example, the following program segment will not compile because the last cout statement cannot access the variable count.
```

for (int count = 1; count <= 10; count++)
cout << count << endl;
cout << "count is now " << count << endl; // ERROR!

```

\section*{Creating a User-Controlled for Loop}

Sometimes you want the user to determine the maximum value of the counter variable in a for loop, and therefore determine the number of times the loop iterates. For example, look at Program 5-10. This is another program that displays a list of numbers and their squares. Instead of displaying the numbers 1 through 10 , this program allows the user to enter the minimum and maximum values to display.

\section*{Program 5-10}
```

// This program demonstrates a user-controlled for loop.
\#include <iostream>
using namespace std;
int main()
{
int minNumber, // Starting number to square
maxNumber; // Maximum number to square

```

9
10
```

    // Get the minimum and maximum values to display.
    cout << "I will display a table of numbers and "
        << "their squares.\n"
        << "Enter the starting number: ";
    cin >> minNumber;
    cout << "Enter the ending number: ";
    cin >> maxNumber;
    // Display the table.
    cout << "Number Number Squared\n"
        << "------------------------\n";
        for (int num = minNumber; num <= maxNumber; num++)
        cout << num << "\t\t" << (num * num) << endl;
        return 0;
    ```
\}

\section*{Program Output with Example Input Shown in Bold}

I will display a table of numbers and their squares.
Enter the starting number: 6 Enter
Enter the ending number: 12 Enter
Number Number Squared
\(6 \quad 36\)
\(7 \quad 49\)
\(8 \quad 64\)
\(9 \quad 81\)
\(10 \quad 100\)
\(11 \quad 121\)
\(12 \quad 144\)

Before the loop, the code in lines 11 through 16 asks the user to enter the starting and ending numbers. These values are stored in the minNumber and maxNumber variables. These values are used in the for loop's initialization and test expressions.
```

for (int num = minNumber; num <= maxNumber; num++)

```

In this loop, the num variable takes on the values from maxNumber through maxValue, and then the loop terminates.

\section*{Using Multiple Statements in the Initialization and Update Expressions}

It is possible to execute more than one statement in the initialization expression and the update expression. When using multiple statements in either of these expressions, simply separate the statements with commas. For example, look at the loop in the following code, which has two statements in the initialization expression:
```

int x, y;
for (x = 1, y = 1; x <= 5; x++)
{
cout << x << " plus " << y
<< " equals " << (x + y)
<< endl;
}

```

This loop's initialization expression is
\[
x=1, y=1
\]

This initializes two variables, \(x\) and \(y\). The output produced by this loop is
\begin{tabular}{lllll}
1 & plus & 1 & equals & 2 \\
2 & plus & 1 & equals & 3 \\
3 & plus & 1 & equals & 4 \\
4 & plus & 1 & equals & 5 \\
5 & plus & 1 & equals & 6
\end{tabular}

We can further modify the loop to execute two statements in the update expression. Here is an example:
```

int x, y;
for (x = 1, y = 1; x <= 5; x++, y++)
{
cout << x << " plus " << y
<< " equals " << (x + y)
<< endl;
}

```

The loop's update expression is
```

x++, y++

```

This update expression increments both the x and y variables. The output produced by this loop is
```

1 plus 1 equals 2
2 plus 2 equals 4
3 plus 3 equals 6
4 plus 4 equals 8
5 plus 5 equals 10

```

Connecting multiple statements with commas works well in the initialization and update expressions, but do not try to connect multiple expressions this way in the test expression. If you wish to combine multiple expressions in the test expression, you must use the \&\& or || operators.

\section*{Omitting the for Loop's Expressions}

The initialization expression may be omitted from inside the for loop's parentheses if it has already been performed or no initialization is needed. Here is an example of the loop in Program 5-10 with the initialization being performed prior to the loop:
```

int num = 1;
for ( ; num <= maxValue; num++)
cout << num << "\t\t" << (num * num) << end1;

```

You may also omit the update expression if it is being performed elsewhere in the loop or if none is needed. Although this type of code is not recommended, the following for loop works just like a while loop:
```

int num = 1;
for ( ; num <= maxValue; )
{
cout << num << "\t\t" << (num * num) << endl;
num++;
}

```

You can even go so far as to omit all three expressions from the for loop's parentheses. Be warned, however, that if you leave out the test expression, the loop has no built-in way of terminating. Here is an example:
```

for ( ; ; )
cout << "Hello World\n";

```

Because this loop has no way of stopping, it will display "Hello World\n" forever (or until something interrupts the program).

\section*{In the Spotlight:}

\section*{Designing a Count-Controlled Loop with the for Statement}

Your friend Amanda just inherited a European sports car from her uncle. Amanda lives in the United States, and she is afraid she will get a speeding ticket because the car's speedometer indicates kilometers per hour. She has asked you to write a program that displays a table of speeds in kilometers per hour with their values converted to miles per hour. The formula for converting kilometers per hour to miles per hour is:
\(M P H=K P H^{*} 0.6214\)
In the formula, MPH is the speed in miles per hour and \(K P H\) is the speed in kilometers per hour.
The table your program displays should show speeds from 60 kilometers per hour through 130 kilometers per hour, in increments of 10 , along with their values converted to miles per hour. The table should look something like this:
\begin{tabular}{cc} 
KPH & MPH \\
\hline 60 & 37.3 \\
70 & 43.5 \\
80 & 49.7 \\
\(\vdots\) & \\
130 & 80.8
\end{tabular}

After thinking about this table of values, you decide that you will write a for loop that uses a counter variable to hold the kilometer-per-hour speeds. The counter's starting value will be 60 , its ending value will be 130 , and you will add 10 to the counter variable after each iteration. Inside the loop, you will use the counter variable to calculate a speed in miles per hour. Program 5-11 shows the code.

\section*{Program 5-11}
```

// This program converts the speeds 60 kph through
// 130 kph (in 10 kph increments) to mph.
\#include <iostream>
\#include <iomanip>
using namespace std;
int main()
{
// Constants for the speeds
const int START_KPH = 60, // Starting speed
END_KPH = 130, // Ending speed
INCREMENT = 10; // Speed increment
// Constant for the conversion factor
const double CONVERSION_FACTOR = 0.6214;
// Variables
int kph; // To hold speeds in kph
double mph; // To hold speeds in mph
// Set the numeric output formatting.
cout << fixed << showpoint << setprecision(1);
// Display the table headings.
cout << "KPH\tMPH\n";
cout << "---------------\n";
// Display the speeds.
for (kph = START_KPH; kph <= END_KPH; kph += INCREMENT)
{
// Calculate mph
mph = kph * CONVERSION_FACTOR;
// Display the speeds in kph and mph.
cout << kph << "\t" << mph << endl;
}
return 0;
}

```

\section*{Program Output}
```

KPH MPH

```
\(60 \quad 37.3\)
\(70 \quad 43.5\)
\(80 \quad 49.7\)
\(90 \quad 55.9\)
\(100 \quad 62.1\)
\(110 \quad 68.4\)
\(120 \quad 74.6\)
\(130 \quad 80.8\)

\section*{Checkpoint}
5.6 Name the three expressions that appear inside the parentheses in the for loop's header.
5.7 You want to write a for loop that displays "I love to program" 50 times. Assume you will use a counter variable named count.
A) What initialization expression will you use?
B) What test expression will you use?
C) What update expression will you use?
D) Write the loop.
5.8 What will the following program segments display?
A) for (int count \(=0\); count \(<6\); count++) cout << (count + count);
B) for (int value \(=-5\); value \(<5\); value++) cout << value;
C) int \(x\); for ( \(\mathrm{x}=5\); \(\mathrm{x}<=14\); \(\mathrm{x}+=3\) ) cout << x << endl; cout \(\ll \mathrm{x} \ll\) endl;
5.9 Write a for loop that displays your name 10 times.
5.10 Write a for loop that displays all of the odd numbers, 1 through 49.
5.11 Write a for loop that displays every fifth number, 0 through 100.

\subsection*{5.7 Keeping a Running Total}

CONCEPT: A running total is a sum of numbers that accumulates with each iteration of a loop. The variable used to keep the running total is called an accumulator.

Many programming tasks require you to calculate the total of a series of numbers. For example, suppose you are writing a program that calculates a business's total sales for a week. The program would read the sales for each day as input and calculate the total of those numbers.

Programs that calculate the total of a series of numbers typically use two elements:
1. A loop that reads each number in the series.
2. A variable that accumulates the total of the numbers as they are read.

The variable that is used to accumulate the total of the numbers is called an accumulator. It is often said that the loop keeps a running total because it accumulates the total as it reads each number in the series. Figure 5-11 shows the general logic of a loop that calculates a running total.

Figure 5-11 Logic for calculating a running total

When the loop finishes, the accumulator will contain the total of the numbers that were read by the loop. Notice the first step in the flowchart is to set the accumulator variable to 0 . This is a critical step. Each time the loop reads a number, it adds it to the accumulator. If the accumulator starts with any value other than 0 , it will not contain the correct total when the loop finishes.

Let's look at a program that calculates a running total. Program 5-12 calculates a company's total sales over a period of time by taking daily sales figures as input and calculating a running total of them as they are gathered.

\section*{Program 5-12}
```

// This program takes daily sales amounts over a period of time
// and calculates their total.
\#include <iostream>
\#include <iomanip>
using namespace std;
int main()
{
int days; // Number of days
double total = 0.0; // Accumulator, initialized with 0
// Get the number of days.
cout << "For how many days do you have sales amounts? ";

```
```

14
15
16
1 7
18
19
20
21
22
23
24
25
26
27
28
29 }

```

\section*{Program Output with Example Input Shown in Bold}

For how many days do you have sales amounts? 5 Enter
Enter the sales for day 1: 489.32 Enter
Enter the sales for day 2: 421.65 Enter
Enter the sales for day 3: 497.89 Enter
Enter the sales for day 4: \(\mathbf{5 3 2 . 3 7}\) Enter
Enter the sales for day 5: 506.92 Enter
The total sales are \(\$ 2448.15\)

Let's take a closer look at this program. Line 9 defines the days variable, which will hold the number of days for which we have sales figures. Line 10 defines the total variable, which will hold the total sales. Because total is an accumulator, it is initialized with 0.0.

In line 14 , the user enters the number of days for which he or she has sales amounts. The number is assigned to the days variable. Next, the for loop in lines 17 through 23 executes. In the loop's initialization expression, in line 17, the variable count is defined and initialized with 1 . The test expression specifies the loop will repeat as long as count is less than or equal to days. The update expression increments count by one at the end of each loop iteration.

Line 19 defines a variable named sales. Because the variable is defined in the body of the loop, its scope is limited to the loop. During each loop iteration, the user enters the amount of sales for a specific day, which is assigned to the sales variable. This is done in line 21. Then, in line 22 , the value of sales is added to the existing value in the total variable. (Note line 22 does not assign sales to total, but adds sales to total. Put another way, this line increases total by the amount in sales.)

Because total was initially assigned 0.0 , after the first iteration of the loop, total will be set to the same value as sales. After each subsequent iteration, total will be increased by the amount in sales. After the loop has finished, total will contain the total of all the daily sales figures entered. Now it should be clear why we assigned 0.0 to total before the loop executed. If total started at any other value, the total would be incorrect.

\subsection*{5.8 Sentinels}

CONCEPT: A sentinel is a special value that marks the end of a list of values.
Program 5-12, in the previous section, requires the user to know in advance the number of days for which he or she wishes to enter sales figures. Sometimes, the user has a list that is very long and doesn't know how many items there are. In other cases, the user might be entering several lists, and it is impractical to require that every item in every list be counted.

A technique that can be used in these situations is to ask the user to enter a sentinel at the end of the list. A sentinel is a special value that cannot be mistaken as a member of the list and signals that there are no more values to be entered. When the user enters the sentinel, the loop terminates.

Program 5-13 calculates the total points earned by a soccer team over a series of games. It allows the user to enter the series of game points, then -1 to signal the end of the list.

\section*{Program 5-13}
```

// This program calculates the total number of points a
// soccer team has earned over a series of games. The user
// enters a series of point values, then -1 when finished.
\#include <iostream>
using namespace std;
int main()
{
int game = 1, // Game counter
points, // To hold a number of points
tota1 = 0; // Accumulator
cout << "Enter the number of points your team has earned\n";
cout << "so far in the season, then enter -1 when finished.\n\n";
cout << "Enter the points for game " << game << ": ";
cin >> points;
while (points != -1)
{
total += points;
game++;
cout << "Enter the points for game " << game << ": ";
cin >> points;
}
cout << "\nThe total points are " << total << endl;
return 0;
}

```
```

Program Output with Example Input Shown in Bold
Enter the number of points your team has earned
so far in the season, then enter -1 when finished.
Enter the points for game 1: 7 Enter
Enter the points for game 2: 9 Enter
Enter the points for game 3: 4 Enter
Enter the points for game 4: 6 Enter
Enter the points for game 5: 8 Enter
Enter the points for game 6: -1 Enter
The total points are 34

```

The value -1 was chosen for the sentinel in this program because it is not possible for a team to score negative points. Notice this program performs a priming read in line 18 to get the first value. This makes it possible for the loop to immediately terminate if the user enters -1 as the first value. Also note the sentinel value is not included in the running total.

\section*{Checkpoint}
5.12 Write a for loop that repeats seven times, asking the user to enter a number. The loop should also calculate the sum of the numbers entered.
5.13 In the following program segment, which variable is the counter variable and which is the accumulator?
```

int a, x, y = 0;
for (x = 0; x < 10; x++)
{
cout << "Enter a number: ";
cin >> a;
y += a;
}
cout << "The sum of those numbers is " << y << endl;

```
5.14 Why should you be careful when choosing a sentinel value?
5.15 How would you modify Program 5-13 so any negative value is a sentinel?

\subsection*{5.9 Focus on Software Engineering: Deciding Which Loop to Use}

CONCEPT: Although most repetitive algorithms can be written with any of the three types of loops, each works best in different situations.

Each of the three C++ loops is ideal to use in different situations. Here's a short summary of when each loop should be used:
- The while loop. The while loop is a conditional loop, which means it repeats as long as a particular condition exists. It is also a pretest loop, so it is ideal in situations where you do not want the loop to iterate if the condition is false from the beginning.

For example, validating input that has been read and reading lists of data terminated by a sentinel value are good applications of the while loop.
- The do-while loop. The do-while loop is also a conditional loop. Unlike the while loop, however, do-while is a posttest loop. It is ideal in situations where you always want the loop to iterate at least once. The do-while loop is a good choice for repeating a menu.
- The for loop. The for loop is a pretest loop that has built-in expressions for initializing, testing, and updating. These expressions make it very convenient to use a counter variable to control the number of iterations that the loop performs. The initialization expression can initialize the counter variable to a starting value, the test expression can test the counter variable to determine whether it holds the maximum value, and the update expression can increment the counter variable. The for loop is ideal in situations where the exact number of iterations is known.

\subsection*{5.10 Nested Loops}

CONCEPT: A loop that is inside another loop is called a nested loop.
A nested loop is a loop that appears inside another loop. A clock is a good example of something that works like a nested loop. The second hand, minute hand, and hour hand all spin around the face of the clock. Each time the hour hand increments, the minute hand increments 60 times. Each time the minute hand increments, the second hand increments 60 times.

Here is a program segment with a for loop that partially simulates a digital clock. It displays the seconds from 0 to 59 .
```

cout << fixed << right;
cout.fi11('0');
for (int seconds = 0; seconds < 60; seconds++)
cout << setw(2) << seconds << endl;

```

NOTE: The fill member function of cout changes the fill character, which is a space by default. In the program segment above, the fill function causes a zero to be printed in front of all single digit numbers.

We can add a minutes variable and nest the loop above inside another loop that cycles through 60 minutes.
```

cout << fixed << right;
cout.fi11('0');
for (int minutes = 0; minutes < 60; minutes++)
{
for (int seconds = 0; seconds < 60; seconds++)
{
cout << setw(2) << minutes << ":";
cout << setw(2) << seconds << endl;
}
}

```

To make the simulated clock complete, another variable and loop can be added to count the hours.
```

cout << fixed << right;
cout.fil1('0');
for (int hours = 0; hours < 24; hours++)
{
for (int minutes = 0; minutes < 60; minutes++)
{
for (int seconds = 0; seconds < 60; seconds++)
{
cout << setw(2) << hours << ":";
cout << setw(2) << minutes << ":";
cout << setw(2) << seconds << endl;
}
}
}

```

The output of the previous program segment follows:
00:00:00
00:00:01
00:00:02
(The program will count through each second of 24 hours.)

23:59:59
The innermost loop will iterate 60 times for each iteration of the middle loop. The middle loop will iterate 60 times for each iteration of the outermost loop. When the outermost loop has iterated 24 times, the middle loop will have iterated 1,440 times and the innermost loop will have iterated 86,400 times!
The simulated clock example brings up a few points about nested loops:
- An inner loop goes through all of its iterations for each iteration of an outer loop.
- Inner loops complete their iterations faster than outer loops.
- To get the total number of iterations of a nested loop, multiply the number of iterations of all the loops.

Program 5-14 is another test-averaging program. It asks the user for the number of students and the number of test scores per student. A nested inner loop, in lines 26 through 33, asks for all the test scores for one student, iterating once for each test score. The outer loop in lines 23 through 37 iterates once for each student.

\section*{Program 5-14}
```

// This program averages test scores. It asks the user for the
// number of students and the number of test scores per student.
\#include <iostream>
\#include <iomanip>
using namespace std;

```

\section*{Program 5-14 (continued)}
```

int main()
{
int numStudents, // Number of students
numTests; // Number of tests per student
double total, // Accumulator for total scores
average; // Average test score
// Set up numeric output formatting.
cout << fixed << showpoint << setprecision(1);
// Get the number of students.
cout << "This program averages test scores.\n";
cout << "For how many students do you have scores? ";
cin >> numStudents;
// Get the number of test scores per student.
cout << "How many test scores does each student have? ";
cin >> numTests;
// Determine each student's average score.
for (int student = 1; student <= numStudents; student++)
{
total = 0; // Initialize the accumulator.
for (int test = 1; test <= numTests; test++)
{
double score;
cout << "Enter score " << test << " for ";
cout << "student " << student << ": ";
cin >> score;
tota1 += score;
}
average = total / numTests;
cout << "The average score for student " << student;
cout << " is " << average << ".\n\n";
}
return 0;
}

```

\section*{Program Output with Example Input Shown in Bold}

This program averages test scores.
For how many students do you have scores? 2 Enter
How many test scores does each student have? 3 Enter
Enter score 1 for student 1: 84 Enter
Enter score 2 for student 1: 79 Enter
Enter score 3 for student 1: 97 Enter
The average score for student 1 is 86.7 .
Enter score 1 for student 2: 92 Enter
Enter score 2 for student 2: \(\mathbf{8 8}\) Enter
Enter score 3 for student 2: 94 Enter
The average score for student 2 is 91.3.

\subsection*{5.11 Using Filles for Data Storage}

CONCEPT: When a program needs to save data for later use, it writes the data in a file. The data can then be read from the file at a later time.

The programs you have written so far require the user to reenter data each time the program runs, because data kept in variables and control properties is stored in RAM and disappears once the program stops running. If a program is to retain data between the times it runs, it must have a way of saving it. Data is saved in a file, which is usually stored on a computer's disk. Once the data is saved in a file, it will remain there after the program stops running. Data stored in a file can be then retrieved and used at a later time.

Most of the commercial software that you use on a day-to-day basis store data in files. The following are a few examples:
- Word processors: Word processing programs are used to write letters, memos, reports, and other documents. The documents are then saved in files so they can later be edited and printed.
- Image editors: Image editing programs are used to draw graphics and edit images such as the ones that you take with a digital camera. The images that you create or edit with an image editor are saved in files.
- Spreadsheets: Spreadsheet programs are used to work with numerical data. Numbers and mathematical formulas can be inserted into the rows and columns of the spreadsheet. The spreadsheet can then be saved in a file for later use.
- Games: Many computer games keep data stored in files. For example, some games keep a list of players' names with their scores stored in a file. These games typically display the players' names in order of their scores, from highest to lowest. Some games also allow you to save your current game status in a file so you can quit the game then resume playing it later without having to start from the beginning.
- Web browsers: Sometimes when you visit a webpage, the browser stores a small file known as a cookie on your computer. Cookies typically contain information about the browsing session, such as the contents of a shopping cart.

Programs used in daily business operations rely extensively on files. Payroll programs keep employee data in files, inventory programs keep data about a company's products in files, accounting systems keep data about a company's financial operations in files, and so on.

Programmers usually refer to the process of saving data in a file as writing data to the file. When a piece of data is written to a file, it is copied from a variable in RAM to the file. This is illustrated in Figure 5-12. An output file is a file to which data is written. It is called an output file because the program stores output in it.

The process of retrieving data from a file is known as reading data from the file. When a piece of data is read from a file, it is copied from the file into a variable in RAM. Figure 5-13 illustrates this process. An input file is a file from which data is read. It is called an input file because the program gets input from the file.

Figure 5-12 Writing data to a file

Figure 5-13 Reading data from a file

This section discusses ways to create programs that write data to files and read data from files. When a file is used by a program, three steps must be taken.
1. Open the file-Opening a file creates a connection between the file and the program. Opening an output file usually creates the file on the disk, and allows the program to write data to it. Opening an input file allows the program to read data from the file.
2. Process the file-Data is either written to the file (if it is an output file) or read from the file (if it is an input file).
3. Close the file-After the program is finished using the file, the file must be closed. Closing a file disconnects the file from the program.

\section*{Types of Files}

In general, there are two types of files: text and binary. A text file contains data that has been encoded as text, using a scheme such as ASCII or Unicode. Even if the file contains numbers, those numbers are stored in the file as a series of characters. As a result, the file may be opened and viewed in a text editor such as Notepad. A binary file contains data
that has not been converted to text. Thus, you cannot view the contents of a binary file with a text editor. In this chapter, we work only with text files. In Chapter 12, you will learn to work with binary files.

\section*{File Access Methods}

There are two general ways to access data stored in a file: sequential access and direct access. When you work with a sequential-access file, you access data from the beginning of the file to the end of the file. If you want to read a piece of data that is stored at the very end of the file, you have to read all of the data that comes before it-you cannot jump directly to the desired data. This is similar to the way that older cassette tape players work. If you want to listen to the last song on a cassette tape, you have to either fast-forward over all of the songs that come before it or listen to them. There is no way to jump directly to a specific song.
When you work with a random-access file (also known as a direct access file), you can jump directly to any piece of data in the file without reading the data that comes before it. This is similar to the way a CD player or an MP3 player works. You can jump directly to any song that you want to hear.

This chapter focuses on sequential-access files. Sequential-access files are easy to work with, and you can use them to gain an understanding of basic file operations. In Chapter 12, you will learn to work with random-access files.

\section*{Filenames and File Stream Objects}

Files on a disk are identified by a filename. For example, when you create a document with a word processor then save the document in a file, you have to specify a filename. When you use a utility such as Windows Explorer to examine the contents of your disk, you see a list of filenames. Figure 5-14 shows how three files named cat.jpg, notes.txt, and resume. doc might be represented in Windows Explorer.

Figure 5-14 Three files

resume.doc

Each operating system has its own rules for naming files. Many systems, including Windows, support the use of filename extensions, which are short sequences of characters that appear at the end of a filename preceded by a period (known as a "dot"). For example, the files depicted in Figure 5-14 have the extensions .jpg, .txt, and .doc. The extension usually indicates the type of data stored in the file. For example, the .jpg extension usually indicates that the file contains a graphic image that is compressed according to the JPEG image standard. The .txt extension usually indicates that the file contains text. The .doc extension usually indicates that the file contains a Microsoft Word document.

In order for a program to work with a file on the computer's disk, the program must create a file stream object in memory. A file stream object is an object that is associated with a specific file and provides a way for the program to work with that file. It is called a "stream" object because a file can be thought of as a stream of data.

File stream objects work very much like the cin and cout objects. A stream of data may be sent to cout, which causes values to be displayed on the screen. A stream of data may be read from the keyboard by cin, and stored in variables. Likewise, streams of data may be sent to a file stream object, which writes the data to a file. When data is read from a file, the data flows from the file stream object that is associated with the file into variables.

\section*{Setting Up a Program for File Input/Output}

Just as cin and cout require the iostream file to be included in the program, C++ file access requires another header file. The file <fstream> contains all the declarations necessary for file operations. It is included with the following statement:
```

\#include <fstream>

```

The <fstream> header file defines the data types ofstream, ifstream, and fstream. Before a C++ program can work with a file, it must define an object of one of these data types. The object will be "linked" with an actual file on the computer's disk, and the operations that may be performed on the file depend on which of these three data types you pick for the file stream object. Table 5-1 lists and describes the file stream data types.

Table 5-1 File Stream Objects
\begin{tabular}{ll}
\hline File Stream Data Type & Description \\
\hline ofstream & \begin{tabular}{l} 
Output file stream. You create an object of this data type when you \\
want to create a file and write data to it.
\end{tabular} \\
ifstream & \begin{tabular}{l} 
Input file stream. You create an object of this data type when you \\
want to open an existing file and read data from it.
\end{tabular} \\
fstream & \begin{tabular}{l} 
File stream. Objects of this data type can be used to open files for \\
reading, writing, or both.
\end{tabular} \\
\hline
\end{tabular}

\section*{NOTE: In this chapter, we discuss only the ofstream a
fstream type will be covered in Chapter 12 .
Creating a File Object and Opening a File}

Before data can be written to or read from a file, the following things must happen:
- A file stream object must be created.
- The file must be opened and linked to the file stream object.

The following code shows an example of opening a file for input (reading).
```

ifstream inputFile;
inputFile.open("Customers.txt");

```

The first statement defines an ifstream object named inputFile. The second statement calls the object's open member function, passing the string "Customers.txt" as an argument. In this statement, the open member function opens the Customers.txt file and links it with the inputFile object. After this code executes, you will be able to use the inputFile object to read data from the Customers.txt file.

The following code shows an example of opening a file for output (writing).
```

ofstream outputFile;
outputFile.open("Employees.txt");

```

The first statement defines an ofstream object named outputFile. The second statement calls the object's open member function, passing the string "Employees.txt" as an argument. In this statement, the open member function creates the Employees.txt file and links it with the outputFile object. After this code executes, you will be able to use the outputFile object to write data to the Employees.txt file. It's important to remember that when you call an ofstream object's open member function, the specified file will be created. If the specified file already exists, it will be deleted, and a new file with the same name will be created.

Often, when opening a file, you will need to specify its path as well as its name. For example, on a Windows system the following statement opens the file C : \data \({ }^{\text {inventory. } \mathrm{txt} \text { : }}\)
inputFile.open("C:\\data\\inventory.txt")
In this statement, the file \(\mathrm{C}: \backslash\) data \(\backslash\) inventory.txt is opened and linked with inputFile.

NOTE: Notice the use of two backslashes in the file's path. Two backslashes are needed to represent one backslash in a string literal.

It is possible to define a file stream object and open a file in one statement. Here is an example:
```

ifstream inputFile("Customers.txt");

```

This statement defines an ifstream object named inputFile and opens the Customer.txt file. Here is an example that defines an ofstream object named outputFile and opens the Employees.txt file:
```

ofstream outputFile("Employees.txt");

```

\section*{Closing a File}

The opposite of opening a file is closing it. Although a program's files are automatically closed when the program shuts down, it is a good programming practice to write statements that close them. Here are two reasons a program should close files when it is finished using them:
1. Most operating systems temporarily store data in a file buffer before it is written to a file. A file buffer is a small "holding section" of memory to which file-bound data is first written. When the buffer is filled, all the data stored there is written to the file. This technique improves the system's performance. Closing a file causes any unsaved data that may still be held in a buffer to be saved to its file. This means the data will be in the file if you need to read it later in the same program.
2. Some operating systems limit the number of files that may be open at one time. When a program closes files that are no longer being used, it will not deplete more of the operating system's resources than necessary.

Calling the file stream object's close member function closes a file. Here is an example:
```

inputFile.close();

```

\section*{Writing Data to a File}

You already know how to use the stream insertion operator (<<) with the cout object to write data to the screen. It can also be used with ofstream objects to write data to a file. Assuming outputFile is an ofstream object, the following statement demonstrates using the \(\ll\) operator to write a string literal to a file:
```

outputFile << "I love C++ programming\n";

```

This statement writes the string literal "I love C++ programming \(\backslash n\) " to the file associated with outputFile. As you can see, the statement looks like a cout statement, except the name of the ofstream object name replaces cout. Here is a statement that writes both a string literal and the contents of a variable to a file:
```

outputFile << "Price: " << price << endl;

```

The statement above writes the stream of data to outputFile exactly as cout would write it to the screen: It writes the string "Price: ", followed by the value of the price variable, followed by a newline character.

Program 5-15 demonstrates opening a file, writing data to the file, and closing the file. After this code has executed, we can open the demofile.txt file using a text editor and look at its contents. Figure 5-15 shows how the file's contents will appear in Notepad.

\section*{Program 5-15}
```

// This program writes data to a file.
\#include <iostream>
\#include <fstream>
using namespace std;
int main()
{
ofstream outputFile;
outputFile.open("demofile.txt");
cout << "Now writing data to the file.\n";
// Write four names to the file.
outputFile << "Bach\n";
outputFile << "Beethoven\n";
outputFile << "Mozart\n";
outputFile << "Schubert\n";
// Close the file
outputFile.close();
cout << "Done.\n";
return 0;
}

```

\section*{Program Screen Output}

Now writing data to the file.
Done.

Figure 5-15 Contents of demofile.txt

Notice in lines 14 through 17 of Program 5-15, each string that was written to the file ends with a newline escape sequence ( \(\backslash \mathrm{n}\) ). The newline specifies the end of a line of text. Because a newline is written at the end of each string, the strings appear on separate lines when viewed in a text editor, as shown in Figure 5-15.

Program 5-16 shows what happens if we write the same four names without the n escape sequence. Figure 5-16 shows the contents of the file that Program 5-16 creates. As you can see, all of the names appear on the same line in the file.

\section*{Program 5-16}
```

// This program writes data to a single line in a file.
\#include <iostream>
\#include <fstream>
using namespace std;
int main()
{
ofstream outputFile;
outputFile.open("demofile.txt");
cout << "Now writing data to the file.\n";
// Write four names to the file.
outputFile << "Bach";
outputFile << "Beethoven";
outputFile << "Mozart";
outputFile << "Schubert";
// Close the file
outputFile.close();
cout << "Done.\n";
return 0;
}

```

\section*{Program Screen Output}

Now writing data to the file.
Done.

Figure 5-16 Output written as one line

Program 5-17 shows another example. This program reads three numbers from the keyboard as input then saves those numbers in a file named Numbers.txt.

\section*{Program 5-17}
```

// This program writes user input to a file.
\#include <iostream>
\#include <fstream>
using namespace std;
int main()
{
ofstream outputFile;
int number1, number2, number3;
// Open an output file.
outputFile.open("Numbers.txt");
// Get three numbers from the user.
cout << "Enter a number: ";
cin >> number1;
cout << "Enter another number: ";
cin >> number2;
cout << "One more time. Enter a number: ";
cin >> number3;
// Write the numbers to the file.
outputFile << number1 << endl;
outputFile << number2 << endl;
outputFile << number3 << endl;
cout << "The numbers were saved to a file.\n";
// Close the file
outputFile.close();
cout << "Done.\n";
return 0;
}

```
```

Program Screen Output with Example Input Shown in Bold
Enter a number: 100 Enter
Enter another number: 200 Enter
One more time. Enter a number: 300 Enter
The numbers were saved to a file.
Done.

```

In Program 5-17, lines 23 through 25 write the contents of the number1, number2, and number3 variables to the file. Notice the endl manipulator is sent to the outputFile object immediately after each item. Sending the end 1 manipulator causes a newline to be written to the file. Figure \(5-17\) shows the file's contents displayed in Notepad, using the example input values 100,200 , and 300 . As you can see, each item appears on a separate line in the file because of the end 1 manipulators.

Figure 5-17 Contents of Numbers.txt

Program 5-18 shows an example that reads strings as input from the keyboard then writes those strings to a file. The program asks the user to enter the first names of three friends, then it writes those names to a file named Friends.txt. Figure 5-18 shows an example of the Friends.txt file opened in Notepad.

\section*{Program 5-18}
```

// This program writes user input to a file.
\#include <iostream>
\#include <fstream>
\#include <string>
using namespace std;
int main()
{
ofstream outputFile;
string name1, name2, name3;
// Open an output file.
outputFile.open("Friends.txt");

```
    // Get the names of three friends.
    cout << "Enter the names of three friends. In";
    cout << "Friend \#1: ";
    cin >> name1;
    cout << "Friend \#2: ";
    cin >> name2;
    cout << "Friend \#3: ";
    cin >> name3;
    // Write the names to the file.
    outputFile << name1 << endl;
    outputFile << name2 << endl;
    outputFile << name3 << endl;
    cout << "The names were saved to a file. \n";
    // Close the file
    outputFile.close();
        return 0;
    \}
Program Screen Output with Example Input Shown in Bold
Enter the names of three friends.
Friend \#1: Joe Enter
Friend \#2: Chris Enter
Friend \#3: Geri Enter
The names were saved to a file.

Figure 5-18 Contents of Friends.txt

\section*{Reading Data from a File}

The >> operator reads not only user input from the cin object, but also data from a file. Assuming input File is an if stream object, the following statement shows the >> operator reading data from the file into the variable name:
```

inputFile >> name;

```

Let's look at an example. Assume the file Friends.txt exists, and it contains the names shown in Figure 5-18. Program 5-19 opens the file, reads the names and displays them on the screen, then closes the file.

\section*{Program 5-19}
```

// This program reads data from a file.
\#include <iostream>
\#include <fstream>
\#include <string>
using namespace std;
int main()
{
ifstream inputFile;
string name;
inputFile.open("Friends.txt");
cout << "Reading data from the file.\n";
inputFile >> name; // Read name 1 from the file
cout << name << endl; // Display name 1
inputFile >> name; // Read name 2 from the file
cout << name << endl; // Display name 2
inputFile >> name; // Read name 3 from the file
cout << name << endl; // Display name 3
inputFile.close(); // Close the file
return 0;
}

```

\section*{Program Output}

Reading data from the file.
Joe
Chris
Geri

\section*{The Read Position}

When a file has been opened for input, the file stream object internally maintains a special value known as a read position. A file's read position marks the location of the next byte that will be read from the file. When an input file is opened, its read position is initially set to the first byte in the file. So, the first read operation extracts data starting at the first byte. As data is read from the file, the read position moves forward, toward the end of the file.

Let's see how this works with the example shown in Program 5-19. When the Friends.txt file is opened by the statement in line 12, the read position for the file will be positioned as shown in Figure 5-19.

\section*{Figure 5-19 Initial read position}

Keep in mind when the >> operator extracts data from a file, it expects to read pieces of data that are separated by whitespace characters (spaces, tabs, or newlines). When the statement in line 15 executes, the >> operator reads data from the file's current read position, up to the In character. The data read from the file is assigned to the name object. The In character is also read from the file, but is not included as part of the data. So, the name object will hold the value "Joe" after this statement executes. The file's read position will then be at the location shown in Figure 5-20.

Figure 5-20 The next read position

When the statement in line 18 executes, it reads the next item from the file, which is "Chris", and assigns that value to the name object. After this statement executes, the file's read position will be advanced to the next item, as shown in Figure 5-21.

Figure 5-21 The next read position

When the statement in line 21 executes, it reads the next item from the file, which is "Geri", and assigns that value to the name object. After this statement executes, the file's read position will be advanced to the end of the file, as shown in Figure 5-22.

Figure 5-22 The read position at the end of the file
\begin{tabular}{|l|l|l|l|l|l|l|l|l|l|l|l|l|l|l|}
\hline J & 0 & e & In & C & h & r & i & s & In & G & e & r & i & In \\
\hline
\end{tabular}

\section*{Reading Numeric Data from a Text File}

Remember when data is stored in a text file, it is encoded as text, using a scheme such as ASCII or Unicode. Even if the file contains numbers, those numbers are stored in the file as a series of characters. For example, suppose a text file contains numeric data, such as that shown in Figure 5-17. The numbers that you see displayed in the figure are stored in the file as the strings "10", " 20 ", and " 30 ". Fortunately, you can use the >> operator to read data such as this from a text file into a numeric variable, and the >> operator will automatically convert the data to a numeric data type. Program 5-20 shows an example. It opens the file shown in Figure 5-23, reads the three numbers from the file into int variables, and calculates their sum.

Figure 5-23 Contents of NumericData.txt

\section*{Program 5-20}
```

// This program reads numbers from a file.
\#include <iostream>
\#include <fstream>
using namespace std;
int main()
{
ifstream inFile;
int value1, value2, value3, sum;
// Open the file.
inFile.open("NumericData.txt");
// Read the three numbers from the file.
inFile >> value1;
inFile >> value2;
inFile >> value3;
// Close the file.
inFile.close();
// Calculate the sum of the numbers.
sum = value1 + value2 + value3;
// Display the three numbers.
cout << "Here are the numbers:\n"
<< value1 << " " << value2
<< " " << value3 << endl;
// Display the sum of the numbers.
cout << "Their sum is: " << sum << endl;
return 0;
}

```

\section*{Program Output}

Here are the numbers:
102030
Their sum is: 60

\section*{Using Loops to Process Files}

Although some programs use files to store only small amounts of data, files are typically used to hold large collections of data. When a program uses a file to write or read a large amount of data, a loop is typically involved. For example, look at the code in Program \(5-21\). This program gets sales amounts for a series of days from the user and writes those amounts to a file named Sales.txt. The user specifies the number of days of sales data he or she needs to enter. In the sample run of the program, the user enters sales amounts for 5 days. Figure 5-24 shows the contents of the Sales.txt file containing the data entered by the user in the sample run.

\section*{Program 5-21}
```

// This program reads data from a file.
\#include <iostream>
\#include <fstream>
using namespace std;
int main()
{
ofstream outputFile; // File stream object
int numberOfDays; // Number of days of sales
double sales; // Sales amount for a day
// Get the number of days.
cout << "For how many days do you have sales? ";
cin >> numberOfDays;
// Open a file named Sales.txt.
outputFile.open("Sales.txt");
// Get the sales for each day and write it
// to the file.
for (int count = 1; count <= numberOfDays; count++)
{
// Get the sales for a day.
cout << "Enter the sales for day "
<< count << ": ";
cin >> sales;
// Write the sales to the file.
outputFile << sales << endl;
}
// Close the file.
outputFile.close();
cout << "Data written to Sales.txt\n";
return 0;
}

```

\section*{Program Output (with Input Shown in Bold)}
```

For how many days do you have sales? 5 Enter

```
Enter the sales for day 1: 1000.00 Enter
Enter the sales for day 2: 2000.00 Enter
Enter the sales for day 3: 3000.00 Enter
Enter the sales for day 4: 4000.00 Enter
Enter the sales for day 5: 5000.00 Enter
Data written to sales.txt.

Figure 5-24 Contents of Sales.txt

\section*{Detecting the End of the File}

Quite often a program must read the contents of a file without knowing the number of items that are stored in the file. For example, suppose you need to write a program that displays all of the items in a file, but you do not know how many items the file contains. You can open the file then use a loop to repeatedly read an item from the file and display it. However, an error will occur if the program attempts to read beyond the end of the file. The program needs some way of knowing when the end of the file has been reached so it will not try to read beyond it.

Fortunately, the >> operator not only reads data from a file, but also returns a true or false value indicating whether the data was successfully read or not. If the operator returns true, then a value was successfully read. If the operator returns false, it means that no value was read from the file.

Let's look at an example. A file named ListOfNumbers.txt, which is shown in Figure 5-25, contains a list of numbers. Without knowing how many numbers the file contains, Program 5-22 opens the file, reads all of the values it contains, and displays them.

Figure 5-25 Contents of ListOfNumbers.txt
\begin{tabular}{|l|l|l|l|}
\hline\(\square\) & ListOfNumbers.txt - Notepad & \(\square\) & 回 \\
\hline File & Edit & Format & View Help \\
\hline 100 & & \\
\hline 200 & & & \\
300 & & & \\
400 & & & \\
500 & & & \\
600 & & & \\
700 & & \\
\hline
\end{tabular}

\section*{Program 5-22}
```

// This program reads data from a file.
\#include <iostream>
\#include <fstream>
using namespace std;
int main()
{
ifstream inputFile;
int number;
// Open the file.
inputFile.open("ListOfNumbers.txt");
// Read the numbers from the file and
// display them.
while (inputFile >> number)
{
cout << number << endl;
}
// Close the file.
inputFile.close();
return 0;
}

```

\section*{Program Output}

100
200
300
400
500
600
700

Take a closer look at line 16:
```

while (inputFile >> number)

```

Notice the statement that extracts data from the file is used as the Boolean expression in the while loop. It works like this:
- The expression inputFile >> number executes.
- If an item is successfully read from the file, the item is stored in the number variable, and the expression returns true to indicate that it succeeded. In that case, the statement in line 18 executes and the loop repeats.
- If there are no more items to read from the file, the expression inputFile \(\gg\) number returns false, indicating that it did not read a value. In that case, the loop terminates.

Because the value returned from the >> operator controls the loop, it will read items from the file until the end of the file has been reached.

\section*{Testing for File Open Errors}

Under certain circumstances, the open member function will not work. For example, the following code will fail if the file info.txt does not exist:
```

ifstream inputFile;
inputFile.open("info.txt");

```

There is a way to determine whether the open member function successfully opened the file. After you call the open member function, you can test the file stream object as if it were a Boolean expression. Program 5-23 shows an example.

\section*{Program 5-23}
```

// This program tests for file open errors.
\#include <iostream>
\#include <fstream>
using namespace std;
int main()
{
ifstream inputFile;
int number;
// Open the file.
inputFile.open("BadListOfNumbers.txt");
// If the file successfully opened, process it.
if (inputFile)
{
// Read the numbers from the file and
// display them.
while (inputFile >> number)
{
cout << number << endl;
}

```
```

Program 5-23 (continued)
24 // Close the file.
25
26
27
28
29
30
31
}
32 return 0;
33 }

```

\section*{Program Output (Assume BadListOfNumbers.txt does not exist)}

Error opening the file.

Let's take a closer look at certain parts of the code. Line 12 calls the inputFile object's open member function to open the file ListOfNumbers.txt. Then, the if statement in line 15 tests the value of the inputFile object as if it were a Boolean expression. When tested this way, the inputFile object will give a true value if the file was successfully opened. Otherwise, it will give a false value. The example output shows this program will display an error message if it could not open the file.
Another way to detect a failed attempt to open a file is with the fail member function, as shown in the following code:
```

ifstream inputFile;
inputFile.open("customers.txt");
if (inputFile.fail())
{
cout << "Error opening file.\n";
}
else
{
// Process the file.
}

```

The fail member function returns true when an attempted file operation is unsuccessful. When using file I/O, you should always test the file stream object to make sure the file was opened successfully. If the file could not be opened, the user should be informed and appropriate action taken by the program.

\section*{Letting the User Specify a Filename}

In each of the previous examples, the name of the file that is opened is hard-coded as a string literal into the program. In many cases, you will want the user to specify the name of a file for the program to open. In C++ 11, you can pass a string object as an argument to a file stream object's open member function. Program 5-24 shows an example. This is a modified version of Program 5-23. This version prompts the user to enter the name of the file. In line 15 , the name the user enters is stored in a string object named filename. In line 18 , the filename object is passed as an argument to the open function.

\section*{Program 5-24}
```

// This program lets the user enter a filename.
\#include <iostream>
\#include <string>
\#include <fstream>
using namespace std;
int main()
{
ifstream inputFile;
string filename;
int number;
// Get the filename from the user.
cout << "Enter the filename: ";
cin >> filename;
// Open the file.
inputFile.open(filename);
// If the file successfully opened, process it.
if (inputFile)
{
// Read the numbers from the file and
// display them.
while (inputFile >> number)
{
cout << number << endl;
}
// Close the file.
inputFile.close();
}
else
{
// Display an error message.
cout << "Error opening the file.\n";
}
return 0;
}

```

\section*{Program Output with Example Input Shown in Bold}

Enter the filename: ListOfNumbers.txt Enter
100
200
300
400
500
600
700

\section*{Using the c_str Member Function in Older Versions of C++}

In older versions of the C++ language (prior to C++ 11), a file stream object's open member function will not accept a string object as an argument. The open member function requires you pass the name of the file as a null-terminated string, which is also known as a C-string. String literals are stored in memory as null-terminated C-strings, but string objects are not.
Fortunately, string objects have a member function named c_str that returns the contents of the object formatted as a null-terminated C-string. Here is the general format of how you call the function:
```

stringObject.c_str()

```

In the general format, stringObject is the name of a string object. The c_str function returns the string that is stored in stringObject as a null-terminated C-string.

For example, line 18 in Program 5-24 could be rewritten in the following manner to make the program compatible with an older version of \(\mathrm{C}++\) :
```

inputFile.open(filename.c_str());

```

In this version of the statement, the value that is returned from filename.c_str() is passed as an argument to the open function.

5.18 What is the difference between a text file and a binary file?
5.19 What is the difference between sequential access and random access?
5.20 What type of file stream object do you create if you want to write data to a file?
5.21 What type of file stream object do you create if you want to read data from a file?
5.22 Write a short program that uses a for loop to write the numbers 1 through 10 to a file.
5.23 Write a short program that opens the file created by the program you wrote for Checkpoint 5.22, reads all of the numbers from the file, and displays them.

\subsection*{5.12 Optional Topics: Breaking and Continuing a Loop}

CONCEPT: The break statement causes a loop to terminate early. The continue statement causes a loop to stop its current iteration and begin the next one.

WARNING! Use the break and continue statements with great caution. Because they bypass the normal condition that controls the loop's iterations, these statements make code difficult to understand and debug. For this reason, you should avoid using break and continue whenever possible. However, because they are part of the C++ language, we discuss them briefly in this section.

Sometimes it's necessary to stop a loop before it goes through all its iterations. The break statement, which was used with switch in Chapter 4, can also be placed inside a loop. When it is encountered, the loop stops, and the program jumps to the statement immediately following the loop.

The while loop in the following program segment appears to execute 10 times, but the break statement causes it to stop after the fifth iteration.
```

int count = 0;
while (count++ < 10)
{
cout << count << endl;
if (count == 5)
break;
}

```

Program 5-25 uses the break statement to interrupt a for loop. The program asks the user for a number, then displays the value of that number raised to the powers of 0 through 10 . The user can stop the loop at any time by entering \(Q\).

\section*{Program 5-25}
// This program raises the user's number to the powers
// of 0 through 10.
\#include <iostream>
\#include <cmath>
using namespace std;
int main()
\{
double value;
char choice;
cout << "Enter a number: ";
cin >> value;
cout << "This program will raise " << value;
cout << " to the powers of 0 through 10. In";
for (int count \(=0\); count \(<=10\); count++)
\{
cout << value << " raised to the power of ";
cout \(\ll\) count \(\ll\) " is " << pow(value, count);
cout << " \nEnter Q to quit or any other key ";
cout << "to continue. ";
cin >> choice;
if (choice == 'Q' || choice == 'q') break;
\}
return 0 ;
\}
```

Program 5-25
(continued)
Program Output with Example Input Shown in Bold
Enter a number: 2 Enter
This program will raise 2 to the powers of 0 through 10.
2 raised to the power of 0 is 1
Enter Q to quit or any other key to continue. C Enter
2 raised to the power of 1 is 2
Enter Q to quit or any other key to continue. C Enter
2 raised to the power of 2 is 4
Enter Q to quit or any other key to continue. Q Enter

```

\section*{Using break in a Nested Loop}

In a nested loop, the break statement only interrupts the loop in which it is placed. The following program segment displays five rows of asterisks on the screen. The outer loop controls the number of rows, and the inner loop controls the number of asterisks in each row. The inner loop is designed to display 20 asterisks, but the break statement stops it during the eleventh iteration.
```

for (int row = 0; row < 5; row++)
{
for (int star = 0; star < 20; star++)
{
cout << '*';
if (star == 10)
break;
}
cout << endl;
}

```

The output of the program segment above is:
```

***********
************
***********
***********
************

```

\section*{The continue Statement}

The continue statement causes the current iteration of a loop to end immediately. When continue is encountered, all the statements in the body of the loop that appear after it are ignored, and the loop prepares for the next iteration.
In a while loop, this means the program jumps to the test expression at the top of the loop. As usual, if the expression is still true, the next iteration begins. In a do-while loop, the program jumps to the test expression at the bottom of the loop, which determines whether the next iteration will begin. In a for loop, continue causes the update expression to be executed, then the test expression to be evaluated.
The following program segment demonstrates the use of continue in a while loop:
```

int testVal = 0;
while (testVal++ < 10)
{
if (testVa1 == 4)
continue;
cout << testVal << " ";
}

```

This loop looks like it displays the integers 1 through 10 . When testVal is equal to 4 , however, the continue statement causes the loop to skip the cout statement and begin the next iteration. The output of the loop is
```

123567 8 9 10

```

Program 5-26 demonstrates the continue statement. The program calculates the charges for DVD rentals, where current releases cost \(\$ 3.50\) and all others cost \(\$ 2.50\). If a customer rents several DVDs, every third one is free. The continue statement is used to skip the part of the loop that calculates the charges for every third DVD.

\section*{Program 5-26}
```

// This program calculates the charges for DVD rentals.
// Every third DVD is free.
\#include <iostream>
\#include <iomanip>
using namespace std;
int main()
{
int dvdCount = 1; // DVD counter
int numDVDs; // Number of DVDs rented
double total = 0.0; // Accumulator
char current; // Current release, Y or N
// Get the number of DVDs.
cout << "How many DVDs are being rented? ";
cin >> numDVDs;
// Determine the charges.
do
{
if ((dvdCount % 3) == 0)
{
cout << "DVD \#" << dvdCount << " is free!\n";
continue; // Immediately start the next iteration
}
cout << "Is DVD \#" << dvdCount;
cout << " a current release? (Y/N) ";
cin >> current;
if (current == 'Y' || current == 'y')
total += 3.50;
else
total += 2.50;
} while (dvdCount++ < numDVDs);

```
```

Program 5-26 (continued)
35 // Display the total.
36 cout << fixed << showpoint << setprecision(2);
37 cout << "The total is \$" << total << endl;
38 return 0;
39 }

```

\section*{Program Output with Example Input Shown in Bold}
```

How many DVDs are being rented? 6 Enter

```
How many DVDs are being rented? 6 Enter
Is DVD #1 a current release? (Y/N) y Enter
Is DVD #1 a current release? (Y/N) y Enter
Is DVD #2 a current release? (Y/N) n Enter
Is DVD #2 a current release? (Y/N) n Enter
DVD #3 is free!
DVD #3 is free!
Is DVD #4 a current release? (Y/N) n Enter
Is DVD #4 a current release? (Y/N) n Enter
Is DVD #5 a current release? (Y/N) y Enter
Is DVD #5 a current release? (Y/N) y Enter
DVD #6 is free!
DVD #6 is free!
The total is $12.00
```

The total is \$12.00

```

Case Study: See the Loan Amortization Case Study on the Computer Science Portal at www.pearsonglobaleditions.com/gaddis.

\section*{Review Questions and Exercises}

\section*{Short Answer}
1. Why should you indent the statements in the body of a loop?
2. Describe the difference between pretest loops and posttest loops.
3. Why are the statements in the body of a loop called conditionally executed statements?
4. What is the difference between the while loop and the do-while loop?
5. Which loop should you use in situations where you wish the loop to repeat until the test expression is false, and the loop should not execute if the test expression is false to begin with?
6. Which loop should you use in situations where you wish the loop to repeat until the test expression is false, but the loop should execute at least one time?
7. Explain the concept of a user-controlled loop. Which loop(s) can be used as a usercontrolled loop? Give an example to support your answer.
8. Why is it critical that counter variables be properly initialized?
9. Why is it critical that accumulator variables be properly initialized?
10. Why should you be careful not to place a statement in the body of a for loop that changes the value of the loop's counter variable?
11. What header file do you need to include in a program that performs file operations?
12. What data type do you use when you want to create a file stream object that can write data to a file?
13. What data type do you use when you want to create a file stream object that can read data from a file?
14. Why should a program close a file when it's finished using it?
15. What is a file's read position? Where is the read position when a file is first opened for reading?

\section*{Fill-in-the-Blank}
16. To \(\qquad\) a value means to increase it by one, and to \(\qquad\) a value means to decrease it by one.
17. In the \(\qquad\) mode of increment operator, the precedence of the increment operator is higher than all other operators in the expression except brackets.
18 When the increment or decrement operator is placed after the operand (or to the operand's right), the operator is being used in \(\qquad\) mode.
19. The three looping structures that \(\mathrm{C}++\) supports are \(\qquad\) , \(\qquad\) , and
\(\qquad\) -.
20. The first line of a while loop or a for loop is generally called a \(\qquad\) .
21. A loop that evaluates its test expression before each repetition is \(a(n)\) \(\qquad\) loop.
22. A \(\qquad\) loop is a type of posttest loop.
23. A loop that does not have a way of stopping is \(a(n)\) \(\qquad\) loop.
24. A block of statements is enclosed within \(\qquad\) _.
25. A(n) \(\qquad\) is a sum of numbers that accumulates with each iteration of a loop.
26. A(n) \(\qquad\) is a variable that is initialized to some starting value, usually zero, then has numbers added to it in each iteration of a loop.
27. A(n) \(\qquad\) is a special value that marks the end of a series of values.
28. The \(\qquad\) loop always iterates at least once.
29. The \(\qquad\) and \(\qquad\) loops will not iterate at all if their test expressions are false to start with.
30. The \(\qquad\) loop is ideal for situations that require a counter.
31. Inside the for loop's parentheses, the first expression is the \(\qquad\) , the second expression is the \(\qquad\) , and the third expression is the \(\qquad\) .
32. A loop that is inside another is called \(a(n)\) \(\qquad\) loop.
33. The header file fstream contains all declarations necessary for \(\qquad\) .
34. An object of \(\qquad\) data type is created when an existing file is opened such that the data can be read from it.

\section*{Algorithm Workbench}
35. Write a while loop that asks the user for a number (integer) and finds the sum of all the numbers entered. The process is continued till the sum of the numbers exceeds 100. Initialize the sum as 0 and display all partial sums.
36. Write a do-while loop that asks the user for a number. The square root of the number is then computed and displayed. The process continues as long as the user inputs a positive number; otherwise the loop terminates. Assume that the first number is 1.
37. Write a for loop to display the following set of numbers:

2, 4, 8, \(16 \ldots 1024,2048\)
38. Write a for loop to display all the even numbers from 100 to 250 . Also include a counter variable that counts the number of even numbers generated.
39. Write a nested loop that displays 10 rows of '\#' characters. There should be 15 ' \(\#\) ' characters in each row.
40. Convert the following while loop to a do-while loop:
```

int x = 1;
while (x > 0)
{
cout << "enter a number: ";
cin >> x;
}

```
41. Convert the following do-while loop to a for loop:
int response;
do
\{
        cout << "Hello! Press 1 to exit loop...";
        cin >> response;
\} while ( response != 1 );
42. Convert the following while loop to a for loop:
```

int count = 0;

```
while (count < 50)
\{
    cout << "count is " << count << end1;
    count++;
\}
43. Convert the following for loop to a while loop:
```

for (int x = 50; x > 0; x--)
{
cout << x << " seconds to go.\n";
}

```
44. Write code that does the following: Opens an output file with the filename Numbers.txt, uses a loop to write the numbers 1 through 100 to the file, then closes the file.
45. Write code that does the following: Opens the Numbers.txt file that was created by the code you wrote in Question 44, reads all of the numbers from the file and displays them, then closes the file.
46. Modify the code that you wrote in Question 45 so it adds all of the numbers read from the file and displays their total.

\section*{True or False}
47. T F The operand of the increment and decrement operators can be any valid mathematical expression.
48. T F The value of the variable z after execution of the following statements will be 11:
\[
\begin{aligned}
& x=y=5 ; \\
& z=x+++y ;
\end{aligned}
\]
49. \(\mathrm{T} \quad \mathrm{F}\) The value of the variable z after execution of the following statements will be 11:
\[
\begin{aligned}
& x=y=5 ; \\
& z=x+++y ;
\end{aligned}
\]
50. T F The while loop is a pretest loop.
51. T F The do-while loop is a pretest loop.
52. T F The for loop is a posttest loop.
53. T F It is not necessary to initialize counter variables.
54. T F Omission of test expression in a for loop results in an infinite loop.
55. T F In a for loop, multiple test expressions may be present and each test expression is separated from the next by a comma.
56. T F Variables may be defined inside the body of a loop.
57. T F Variables may be defined in the conditional expression of a while loop.
58. T F In a nested loop, the outer loop executes faster than the inner loop.
59. T F In a nested loop, the inner loop goes through all of its iterations for every single iteration of the outer loop.
60. T F In a nested loop, if the outer loop has \(m\) iterations and the inner loop has \(n\) iterations, then the total number of iterations will be \(m \times n\).
61. T F The break statement causes a loop to stop the current iteration and begin the next one.
62. T F The continue statement causes a terminated loop to resume.
63. T F The stream extraction operator can be used to write data to a file.
64. T F When you call an ofstream object's open member function, the specified file will be erased if it already exists.

\section*{Find the Errors}

Each of the following programs has errors. Find as many as you can.
```

65. // Find the error in this program.
\#include <iostream>
using namespace std;
int main()
{
int num1 = 0, num2 = 10, result;
num1++;
result = ++(num1 + num2);
cout << num1 << " " << num2 << " " << result;
return 0;
}
```
66. // This program adds and finds the greater of two numbers.
    \#include <iostream>
    using namespace std;
    int main()
    \{
        int num1, num2;
        char again \(=\) ' \(Y\) ';
        do
        \{
            cout << "Enter two numbers: ";
            cin >> num1 >> num2;
            if ( num1 > num2 ) cout << num1;
            cout << "Do you want to do this again? ";
            cin >> again;
        \} while (again = 'y' || again = 'Y');
        return 0;
    \}
```

67. // This program uses a loop to raise a number to a power.
\#include <iostream>
using namespace std;
int main()
{
int num, bigNum, power, count;
cout << "Enter an integer: ";
cin >> num;
cout << "What power do you want it raised to? ";
cin >> power;
bigNum = num;
while (count++ < power);
bigNum *= num;
cout << "The result is << bigNum << endl;
return 0;
}
68. // This program averages a set of numbers.
\#include <iostream>
using namespace std;
int main()
{
int numCount, total;
double average;
cout << "How many numbers do you want to average? ";
cin >> numCount;
for (int count = 0; count < numCount; count++)
{
int num;
cout << "Enter a number: ";
cin >> num;
total += num;
count++;
}
average = total / numCount;
cout << "The average is << average << endl;
return 0;
}
69. // This program displays the sum of two numbers.
\#include <iostream>
using namespace std;
int main()
{
int choice, num1, num2;
```
```

        do
        {
            cout << "Enter a number: ";
            cin >> num1;
            cout << "Enter another number: ";
            cin >> num2;
            cout << "Their sum is " << (num1 + num2) << end1;
            cout << "Do you want to do this again?\n";
            cout << "1 = yes, 0 = no\n";
            cin >> choice;
        } while (choice = 1)
    return 0;
    }
    ```
70. // This program displays the sum of the numbers 1-100.
    \#include <iostream>
    using namespace std;
    int main()
    \{
    int count \(=1\), total;
    while (count <= 100)
            tota1 += count;
        cout << "The sum of the numbers 1-100 is ";
        cout << total << endl;
        return 0 ;
    \}

\section*{Programming Challenges}
1. Sum of Numbers

Write a program that asks the user for a positive integer value. The program should use a loop to get the sum of all the integers from 1 up to the number entered. For example, if the user enters 50 , the loop will find the sum of \(1,2,3,4, \ldots, 50\).
Input Validation: Do not accept a negative starting number.

\section*{2. Multiplication Tables}

Write a program that lets the user enter a number and then displays the multiplication table till 10 for that number.
3. Conversion Table from Degrees to Radians

Write a program to generate a table of conversion from degrees to radians. The value of degrees should start with \(0^{\circ}\) and end with \(90^{\circ}\). Increment each row from the previous one by \(10^{\circ}\). (Note that \(\pi=180^{\circ}=3.141593\) radians.)

Solving the Calories Burned Problem

\section*{4. Calories Burned}

Running on a particular treadmill you burn 3.6 calories per minute. Write a program that uses a loop to display the number of calories burned after \(5,10,15,20,25\), and 30 minutes.
5. Harmonic Sum

Write a program that calculates the \(n\)th harmonic number \(H_{n}\) using the following formula:
\(H_{n}=1+\frac{1}{2}+\frac{1}{3}+\cdots+\frac{1}{n}\)

\section*{6. Distance Traveled}

The distance a vehicle travels can be calculated as follows:
distance \(=\) speed * time
For example, if a train travels 40 miles per hour for 3 hours, the distance traveled is 120 miles.

Write a program that asks the user for the speed of a vehicle (in miles per hour) and how many hours it has traveled. The program should then use a loop to display the distance the vehicle has traveled for each hour of that time period. Here is an example of the output:
```

What is the speed of the vehicle in mph? 40
How many hours has it traveled? 3
Hour Distance Traveled
*-----------------------------
1 40
2 80
3 120

```

Input Validation: Do not accept a negative number for speed and do not accept any value less than 1 for time traveled.

\section*{7. Arithmetic Series}

Write a program that asks the user for three values: an initial value for an arithmetic series, a second value for the series, and the number of values that should be calculated and displayed. The difference between the second and the first value determines the increment for the series.
Input Validation: The number of values has to be greater than 0 .
Alternate Version: Write a program that takes as the third value an upper limit for the series. If the user enters 100 as the third value, the series stops as soon as it equals or exceeds 100.

\section*{8. Math Tutor}

This program started in Programming Challenge 17, of Chapter 3, and was modified in Programming Challenge 11 of Chapter 4. Modify the program again so it displays a menu allowing the user to select an addition, subtraction, multiplication, or division problem. The final selection on the menu should let the user quit the program. After the user has finished the math problem, the program should display the menu again. This process is repeated until the user chooses to quit the program.
Input Validation: If the user selects an item not on the menu, display an error message and display the тепи again.

\section*{9. The Collatz Conjecture}

Write a program that lets the user enter a positive integer and then reduces that value to 1 by performing the following steps:
- If the value of \(n\) is even, continue with \(n / 2\).
- If \(n\) is odd, continue with \(3 n+1\).

Display the intermediate steps and finally display the number of steps needed to reach 1 .
Input Validation: Make sure that the number entered is greater than 0.

The conjecture that this always converges to 1 was formulated by Lothar Collatz in 1937 and is still an unsolved problem in mathematics, despite a claim of proof in 2011.
10. Palindrome Check

A number is called a palindrome if it remains unchanged when its digits are reversed. Write a program to accept a nonzero positive number. The program should loop till the user inputs a valid number. The program should then generate the reversed number. If the reversed number is equal to the original, a message should be displayed that the number is a palindrome.
Hint: To find the reverse of a number, you can follow this procedure to reverse a number \(n\). Initialize reversed number revno to 0 . Divide \(n\) by 10 and store the remainder in \(r\). Then add the remainder \(r\) to revno multiplied by 10. Repeat continually until \(n\) becomes 0 .

\section*{11. Population}

Write a program that will predict the size of a population of organisms. The program should ask the user for the starting number of organisms, their average daily population increase (as a percentage), and the number of days they will multiply. A loop should display the size of the population for each day.
Input Validation: Do not accept a number less than 2 for the starting size of the population. Do not accept a negative number for average daily population increase. Do not accept a number less than 1 for the number of days they will multiply.
12. Celsius to Fahrenheit Table

In Programming Challenge 12 of Chapter 3, you were asked to write a program that converts a Celsius temperature to Fahrenheit. Modify that program so that it uses a loop to display a table of the Celsius temperatures \(0-20\), and the Fahrenheit equivalents.
13. Sum of a Series

Write a program that displays the following series and also finds its sum:
\[
\frac{2}{1^{2}}+\frac{4}{2^{2}}+\frac{6}{3^{2}}+\frac{8}{4^{2}}+\frac{10}{5^{2}}+\cdots \cdots \cdots \cdots \cdots \cdot+\frac{20}{10^{2}}
\]

\section*{14. Student Line Up}

A teacher has asked all her students to line up according to their first name. For example, in one class Amy will be at the front of the line, and Yolanda will be at the end. Write a program that prompts the user to enter the number of students in the class, then loops to read that many names. Once all the names have been read, it reports which student would be at the front of the line and which one would be at the end of the line. You may assume that no two students have the same name.
Input Validation: Do not accept a number less than 1 or greater than 25 for the number of students.
15. Estimated Wait Time

Waiting in queues is rarely enjoyable. What makes it worse is when you seem to always pick the slowest queue. Write a program that lets the user input the number of articles in each shopping cart in a queue. Each number entered corresponds to one shopping cart. To end the input, the user enters 0 . The program should then display
the estimated waiting time in minutes and seconds. The waiting time is composed of 0.75 seconds per article and an additional 30 seconds per shopping cart.

Input Validation: All values must be either strictly positive or 0.

\section*{16. Savings Account Balance}

Write a program that calculates the balance of a savings account at the end of a period of time. It should ask the user for the annual interest rate, the starting balance, and the number of months that have passed since the account was established. A loop should then iterate once for every month, performing the following:
A) Ask the user for the amount deposited into the account during the month. (Do not accept negative numbers.) This amount should be added to the balance.
B) Ask the user for the amount withdrawn from the account during the month. (Do not accept negative numbers.) This amount should be subtracted from the balance.
C) Calculate the monthly interest. The monthly interest rate is the annual interest rate divided by 12 . Multiply the monthly interest rate by the balance, and add the result to the balance.
After the last iteration, the program should display the ending balance, the total amount of deposits, the total amount of withdrawals, and the total interest earned.

NOTE: If a negative balance is calculated at any point, a message should be displayed indicating the account has been closed and the loop should terminate.

\section*{17. Pattern Generator}

Write a program the lets the user input in the following order:
- A character
- An integer ' \(n\) ' for the number of times this character has to be repeated
- Another character
- Another integer ' \(m\) ' for the number of times the second character has to be repeated
- Two integers for the number of rows and columns

The program should generate a pattern based on the input parameters. The pattern is composed of the repetition of ' \(n\) ' times the first character and ' \(m\) ' times the second character up until all rows have been filled with the specified number of characters.
If, for example, '*' must be repeated thrice and ' + ' twice in 4 rows of 21 columns, the pattern looks like this:
```

***++***++***++****+*
**++***++***++***++**
*++***++***++***++***
++***++***++***++***+

```

\section*{18. Population Bar Chart}

Write a program that produces a bar chart showing the population growth of Prairieville, a small town in the Midwest, at 20-year intervals during the past 100 years. The program
should read in the population figures (rounded to the nearest 1,000 people) for 1900, 1920, 1940, 1960, 1980, and 2000 from a file. For each year, it should display the date and a bar consisting of one asterisk for each 1,000 people. The data can be found in the People.txt file.
Here is an example of how the chart might begin:
PRAIRIEVILLE POPULATION GROWTH
(each * represents 1,000 people)
1900 **
1920 ****
1940 *****
19. Count Positive and Negative Numbers

Write a program that asks the user for a positive integer n within 10 to 20 . The program should loop till the user inputs a valid number. After receiving a valid input, it should prompt the user to enter \(n\) numbers within a loop and count the total number of positive and negative numbers separately.

\section*{20. Random Number Guessing Game}

Write a program that generates a random number and asks the user to guess what the number is. If the user's guess is higher than the random number, the program should display "Too high, try again." If the user's guess is lower than the random number, the program should display "Too low, try again." The program should use a loop that repeats until the user correctly guesses the random number.

\section*{21. Random Number Guessing Game Enhancement}

Enhance the program that you wrote for Programming Challenge 20 so it keeps a count of the number of guesses the user makes. When the user correctly guesses the random number, the program should display the number of guesses.

\section*{22. Square Display}

Write a program that asks the user for a positive integer no greater than 15 . The program should then display a square on the screen using the character ' X '. The number entered by the user will be the length of each side of the square. For example, if the user enters 5 , the program should display the following:
XXXXX
XXXXX

If the user enters 8 , the program should display the following:
XXXXXXXX
XXXXXXXX
XXXXXXXX
XXXXXXXX
XXXXXXXX
XXXXXXXX
XXXXXXXX
XXXXXXXX

\section*{23. Pattern Displays}

Write a program that uses a loop to display Pattern A below, followed by another loop that displays Pattern B.
\begin{tabular}{ll}
\hline Pattern A & Pattern B \\
\hline+ & ++++++++++ \\
++ & +++++++++ \\
+++ & ++++++++ \\
++++ & +++++++ \\
+++++ & ++++++ \\
++++++ & +++++ \\
+++++++ & ++++ \\
++++++++ & +++ \\
+++++++++ & ++ \\
++++++++++ & + \\
\hline
\end{tabular}
24. Using Files-Numeric Processing

If you have downloaded this book's source code from the Computer Science Portal, you will find a file named Random.txt in the Chapter 05 folder. (The Portal can be found at www.pearsonglobaleditions.com/gaddis.) This file contains a long list of random numbers. Copy the file to your system, then write a program that opens the file, reads all the numbers from the file, and calculates the following:
A) The number of numbers in the file
B) The sum of all the numbers in the file (a running total)
C) The average of all the numbers in the file

The program should display the number of numbers found in the file, the sum of the numbers, and the average of the numbers.
25. Using Files-Student Line Up

Modify the Student Line Up program described in Programming Challenge 14 so it gets the names from a file. Names should be read in until there is no more data to read. If you have downloaded this book's source code you will find a file named LineUp.txt in the Chapter 05 folder. You can use this file to test the program.

\section*{26. Personal Web Page Generator}

Write a program that asks the user for his or her name, then asks the user to enter a sentence that describes himself or herself. Here is an example of the program's screen:

\footnotetext{
Enter your name: Julie Taylor Enter Describe yourself: I am a computer science major, a member of the Jazz club, and I hope to work as a mobile app developer after I graduate. Enter
}

Once the user has entered the requested input, the program should create an HTML file, containing the input, for a simple webpage. Here is an example of the HTML content, using the sample input previously shown:
```

<htm1>

<head>
</head>
<body>
    <center>
        <h1>Julie Tay1or</h1>
    </center>
    <hr />
    I am a computer science major, a member of the Jazz club,
    and I hope to work as a mobile app developer after I graduate.
    <hr />
</body>
</html>

```

\section*{27. Average Steps Taken}

A Personal Fitness Tracker is a wearable device that tracks your physical activity, calories burned, heart rate, sleeping patterns, and so on. One common physical activity that most of these devices track is the number of steps you take each day.
If you have downloaded this book's source code, you will find a file named steps.txt in the Chapter 05 folder. The steps.txt file contains the number of steps a person has taken each day for a year. There are 365 lines in the file, and each line contains the number of steps taken during a day. (The first line is the number of steps taken on January 1, the second line is the number of steps taken on January 2, and so forth.) Write a program that reads the file, then displays the average number of steps taken for each month. (The data is from a year that was not a leap year, so February has 28 days.)

\subsection*{6.1 Focus on Software Engineering: Modular Programming}

\section*{CONCEPT: A program may be broken up into manageable functions.}

A function is a collection of statements that performs a specific task. So far, you have experienced functions in two ways: (1) you have created a function named main in every program you've written, and (2) you have used library functions such as pow and strcmp. In this chapter, you will learn how to create your own functions that can be used like library functions.

Functions are commonly used to break a problem down into small, manageable pieces. Instead of writing one long function that contains all of the statements necessary to solve a problem, several small functions that each solve a specific part of the problem can be written. These small functions can then be executed in the desired order to solve the problem. This approach is sometimes called divide and conquer because a large problem is divided
into several smaller problems that are easily solved. Figure 6-1 illustrates this idea by comparing two programs: one that uses a long, complex function containing all of the statements necessary to solve a problem, and another that divides a problem into smaller problems, each of which is handled by a separate function.

Figure 6-1 Modular programming

This program has one long, complex function containing all of the statements necessary to solve a problem.

int main()
\{
statement;
statement;
statement;
statement;
statement;
statement;
statement;
statement;
statement;
statement;
statement;
statement;
statement;
statement;
statement;
statement;
statement;
statement;
statement;
statement;
statement;
statement;
statement;
statement;
\}

In this program, the problem has been divided into smaller problems, each of which is handled by a separate function.
```

int main()
{
statement;
statement; main function
statement;
}

```
void function2()
\{
    statement;
    statement; function 2
    statement;
\}
```

void function3()
{
statement; function 3
statement;
statement;
}

```
```

void function4()
{
statement; function 4
statement;
statement;
}

```

Another reason to write functions is that they simplify programs. If a specific task is performed in several places in a program, a function can be written once to perform that task, then be executed anytime it is needed. This benefit of using functions is known as code reuse because you are writing the code to perform a task once, then reusing it each time you need to perform the task.

\subsection*{6.2 Defining and Calling Functions}

CONCEPT: A function call is a statement that causes a function to execute. A function definition contains the statements that make up the function.

When creating a function, you must write its definition. All function definitions have the following parts:

Return type: A function can send a value to the part of the program that executed it. The return type is the data type of the value that is sent from the function.

Name: You should give each function a descriptive name. In general, the same rules that apply to variable names also apply to function names.

Parameter list: The program can send data into a function. The parameter list is a list of variables that hold the values being passed to the function.

Body: \(\quad\) The body of a function is the set of statements that perform the function's operation. They are enclosed in a set of braces.

Figure 6-2 shows the definition of a simple function with the various parts labeled.

\section*{Figure 6-2 Function definition}

The line in the definition that reads int main() is called the function beader.

\section*{void Functions}

You already know that a function can return a value. The main function in all of the programs you have seen in this book is declared to return an int value to the operating system. The return 0 ; statement causes the value 0 to be returned when the main function finishes executing.

It isn't necessary for all functions to return a value, however. Some functions simply perform one or more statements, and then terminate. These are called void functions. The displayMessage function, which follows, is an example.
```

void displayMessage()
{
cout << "Hello from the function displayMessage.\n";
}

```

The function's name is displayMessage. This name gives an indication of what the function does: It displays a message. You should always give functions names that reflect their purpose. Notice the function's return type is void. This means the function does not return a value to the part of the program that executed it. Also notice the function has no return statement. It simply displays a message on the screen and exits.

\section*{Calling a Function}

A function is executed when it is called. Function main is called automatically when a program starts, but all other functions must be executed by function call statements. When a function is called, the program branches to that function and executes the statements in its body. Let's look at Program 6-1, which contains two functions: main and displayMessage.

\section*{Program 6-1}
```

// This program has two functions: main and displayMessage
\#include <iostream>
using namespace std;
//*****************************************
// Definition of function displayMessage
// This function displays a greeting.
|/*****************************************
void displayMessage()
{
cout << "Hello from the function displayMessage.\n";
}
//*****************************************
// Function main *
//*****************************************
int main()
{
cout << "Hello from main.\n";
displayMessage();
cout << "Back in function main again.\n";
return 0;
}

```

\section*{Program Output}
```

Hello from main.
Hello from the function displayMessage.
Back in function main again.

```

The function displayMessage is called by the following statement in line 22:
```

displayMessage();

```

This statement is the function call. It is simply the name of the function followed by a set of parentheses and a semicolon. Let's compare this with the function header:
\[
\begin{aligned}
& \text { Function Header } \longrightarrow \text { void displayMessage() } \\
& \text { Function Call } \longrightarrow \text { displayMessage () }
\end{aligned}
\]

The function header is part of the function definition. It declares the function's return type, name, and parameter list. It is not terminated with a semicolon because the definition of the function's body follows it.

The function call is a statement that executes the function, so it is terminated with a semicolon like all other C++ statements. The return type is not listed in the function call, and, if the program is not passing data into the function, the parentheses are left empty.

NOTE: Later in this chapter, you will see how data can be passed into a function by being listed inside the parentheses.

Even though the program starts executing at main, the function displayMessage is defined first. This is because the compiler must know the function's return type, the number of parameters, and the type of each parameter before the function is called. One way to ensure the compiler will know this information is to place the function definition before all calls to that function. (Later, you will see an alternative, preferred method of accomplishing this.)

Notice how Program 6-1 flows. It starts, of course, in function main. When the call to displayMessage is encountered, the program branches to that function and performs its statements. Once displayMessage has finished executing, the program branches back to function main and resumes with the line that follows the function call. This is illustrated in Figure 6-3.

Figure 6-3 A function call

Function call statements may be used in control structures like loops, if statements, and switch statements. Program 6-2 places the displayMessage function call inside a loop.

\section*{Program 6-2}
```

// The function displayMessage is repeatedly called from a loop.
\#include <iostream>
using namespace std;
//******************************************
// Definition of function displayMessage
// This function displays a greeting.
//******************************************
void displayMessage()
{
cout << "Hello from the function displayMessage.\n";
}
//******************************************
// Function main *
//*****************************************
int main()
{
cout << "Hello from main.\n";
for (int count = 0; count < 5; count++)
displayMessage(); // Call displayMessage
cout << "Back in function main again.\n";
return 0;
}

```

\section*{Program Output}

Hello from main.
Hello from the function displayMessage.
Hello from the function displayMessage.
Hello from the function displayMessage.
Hello from the function displayMessage.
Hello from the function displayMessage.
Back in function main again.

It is possible to have many functions and function calls in a program. Program 6-3 has three functions: main, first, and second.

\section*{Program 6-3}
```

// This program has three functions: main, first, and second.
\#include <iostream>
using namespace std;

```
```

//*********************************************
// Definition of function first *
// This function displays a message. *
//*******************************************
void first()
{
cout << "I am now inside the function first.\n";
}
//*****************************************
// Definition of function second
// This function displays a message.
//********************************************
void second()
{
cout << "I am now inside the function second.\n";
}
//*******************************************
// Function main
//*********************************************
int main()
{
cout << "I am starting in function main.\n";
first(); // Call function first
second(); // Call function second
cout << "Back in function main again. \n";
return 0;
}

```

\section*{Program Output}

I am starting in function main.
I am now inside the function first.
I am now inside the function second.
Back in function main again.

In lines 32 and 33 of Program 6-3, function main contains a call to first and a call to second:
```

first();
second();

```

Each call statement causes the program to branch to a function then back to main when the function is finished. Figure 6-4 illustrates the paths taken by the program.

Figure 6-4 Paths taken by the program

Functions may also be called in a hierarchical, or layered, fashion. This is demonstrated by Program 6-4, which has three functions: main, deep, and deeper.

\section*{Program 6-4}
```

// This program has three functions: main, deep, and deeper
\#include <iostream>
using namespace std;
|/*****************************************
// Definition of function deeper *
// This function displays a message. *
|/*****************************************
void deeper()
{
cout << "I am now inside the function deeper.\n";
}
//*****************************************
// Definition of function deep *
// This function displays a message. *
//******************************************

```
```

void deep()
{
cout << "I am now inside the function deep.\n";
deeper(); // Call function deeper
cout << "Now I am back in deep.\n";
}
//******************************************
// Function main
//******************************************
int main()
{
cout << "I am starting in function main.\n";
deep(); // Call function deep
cout << "Back in function main again.\n";
return 0;
}

```

\section*{Program Output}

I am starting in function main.
I am now inside the function deep.
I am now inside the function deeper.
Now I am back in deep.
Back in function main again.

In Program 6-4, function main only calls the function deep. In turn, deep calls deeper. The paths taken by the program are shown in Figure 6-5.

Figure 6-5 Layered function calls

\section*{(1) Checkpoint}
6.1 Is the following a function header or a function call?
```

calcTota1();

```
6.2 Is the following a function header or a function call?
```

void showResults()

```
6.3 What will the output of the following program be if the user enters 10 ?
```

\#include <iostream>
using namespace std;
void func1()
{
cout << "Able was I\n";
}
void func2()
{
cout << "I saw Elba\n";
}
int main()
{
int input;
cout << "Enter a number: ";
cin >> input;
if (input < 10)
{
func1();
func2();
}
else
{
func2();
func1();
}
return 0;
}

```
6.4 The following program skeleton determines whether a person qualifies for a credit card. To qualify, the person must have worked on his or her current job for at least 2 years, and make at least \(\$ 17,000\) per year. Finish the program by writing the definitions of the functions qualify and noQualify. The function qualify should explain that the applicant qualifies for the card, and that the annual interest rate is 12 percent. The function noQualify should explain that the applicant does not qualify for the card and give a general explanation why.
```

\#include <iostream>
using namespace std;
// You must write definitions for the two functions qualify
// and noQualify.

```
```

int main()
{
double salary;
int years;
cout << "This program will determine if you qualify\n";
cout << "for our credit card.\n";
cout << "What is your annual salary? ";
cin >> salary;
cout << "How many years have you worked at your ";
cout << "current job? ";
cin >> years;
if (salary >= 17000.0 \&\& years >= 2)
qualify();
else
noQualify();
return 0;
}

```

\subsection*{6.3 Function Prototypes}

CONCEPT: A function prototype eliminates the need to place a function definition before all calls to the function.

Before the compiler encounters a call to a particular function, it must already know the function's return type, the number of parameters it uses, and the type of each parameter. (You will learn how to use parameters in the next section.)

One way of ensuring that the compiler has this information is to place the function definition before all calls to that function. This was the approach taken in Programs 6-1, 6-2, \(6-3\), and 6-4. Another method is to declare the function with a function prototype. Here is a prototype for the displayMessage function in Program 6-1:
```

void displayMessage();

```

The prototype looks similar to the function header, except there is a semicolon at the end. The statement above tells the compiler that the function displayMessage has a void return type (it doesn't return a value) and uses no parameters.

NOTE: Function prototypes are also known as function declarations.

WARNING! You must place either the function definition or the function prototype ahead of all calls to the function. Otherwise, the program will not compile.

Function prototypes are usually placed near the top of a program so the compiler will encounter them before any function calls. Program 6-5 is a modification of Program 6-3. The definitions of the functions first and second have been placed after main, and a function prototype has been placed after the using namespace std statement.

\section*{Program 6-5}
```

    // This program has three functions: main, first, and second.
    \#include <iostream>
using namespace std;
// Function Prototypes
void first();
void second();
int main()
{
cout << "I am starting in function main.\n";
first(); // Call function first
second(); // Call function second
cout << "Back in function main again.\n";
return 0;
}
//**************************************
// Definition of function first. *
// This function displays a message.
//**************************************
void first()
{
cout << "I am now inside the function first.\n";
}
//****************************************
// Definition of function second. *
// This function displays a message.
//***************************************
void second()
{
cout << "I am now inside the function second.\n";
}

```

\section*{Program Output}
(The program's output is the same as the output of Program 6-3.)

When the compiler is reading Program 6-5, it encounters the calls to the functions first and second in lines 12 and 13 before it has read the definition of those functions. Because of the function prototypes, however, the compiler already knows the return type and parameter information of first and second.

NOTE: Although some programmers make main the last function in the program, many prefer it to be first because it is the program's starting point.

\subsection*{6.4 Sending Data into a Function}

CONCEPT: When a function is called, the program may send values into the function.

Values sent into a function are called arguments. You're already familiar with how to use arguments in a function call. In the following statement, the function pow is being called and two arguments, 2.0 and 4.0, are passed to it:
```

result = pow(2.0, 4.0);

```

By using parameters, you can design your own functions that accept data this way. A parameter is a special variable that holds a value being passed into a function. Here is the definition of a function that uses a parameter:
```

void displayValue(int num)
{
cout << "The value is " << num << endl;
}

```

Notice the integer variable definition inside the parentheses (int num). The variable num is a parameter. This enables the function displayValue to accept an integer value as an argument. Program 6-6 is a complete program using this function.

NOTE: In this text, the values that are passed into a function are called arguments, and the variables that receive those values are called parameters. There are several variations of these terms in use. Some call the arguments actual parameters and call the parameters formal parameters. Others use the terms actual argument and formal argument. Regardless of which set of terms you use, it is important to be consistent.

\section*{Program 6-6}
```

// This program demonstrates a function with a parameter.
\#include <iostream>
using namespace std;
// Function Prototype
void displayValue(int);
int main()
{
cout << "I am passing 5 to displayValue.\n";
displayValue(5); // Call displayValue with argument 5
cout << "Now I am back in main.\n";
return 0;
}

```
15

\section*{Program 6-6}
(continued)
```

//*************************************************************
// Definition of function displayValue.
// It uses an integer parameter whose value is displayed.*
/|***************************************************************
void displayValue(int num)
{
cout << "The value is " << num << endl;
}

```

\section*{Program Output}

I am passing 5 to displayValue.
The value is 5
Now I am back in main.

First, notice the function prototype for displayValue in line 6:
```

void displayValue(int);

```

It is not necessary to list the name of the parameter variable inside the parentheses. Only its data type is required. The function prototype shown above could optionally have been written as
```

void displayValue(int num);

```

However, the compiler ignores the name of the parameter variable in the function prototype.
In main, the displayValue function is called with the argument 5 inside the parentheses. The number 5 is passed into num, which is displayValue's parameter. This is illustrated in Figure 6-6.

Figure 6-6 An argument passed to a function
```

displayValue(5);
void displayValue(int num)
{
cout << "The value is " << num << endl;
}

```

Any argument listed inside the parentheses of a function call is copied into the function's parameter variable. In essence, parameter variables are initialized to the value of their corresponding arguments. Program 6-7 shows the function displayValue being called several times with a different argument being passed each time.

\section*{Program 6-7}
```

// This program demonstrates a function with a parameter.
\#include <iostream>
using namespace std;
// Function Prototype
void displayValue(int);
int main()
{
cout << "I am passing several values to displayValue.\n";
displayValue(5); // Call displayValue with argument 5
displayValue(10); // Call displayValue with argument 10
displayValue(2); // Call displayValue with argument 2
displayValue(16); // Call displayValue with argument 16
cout << "Now I am back in main.\n";
return 0;
}
//***************************************************************
// Definition of function displayValue. *
// It uses an integer parameter whose value is displayed.*
|/***********************************************************
void displayValue(int num)
{
cout << "The value is " << num << endl;
}

```

\section*{Program Output}

I am passing several values to displayValue.
The value is 5
The value is 10
The value is 2
The value is 16
Now I am back in main.

WARNING! When passing a variable as an argument, simply write the variable name inside the parentheses of the function call. Do not write the data type of the argument variable in the function call. For example, the following function call will cause an error: displayValue(int x); // Error!

The function call should appear as
displayValue(x); // Correct
Each time the function is called in Program 6-7, num takes on a different value. Any expression whose value could normally be assigned to num may be used as an argument. For example, the following function call would pass the value 8 into num:
```

displayValue(3 + 5);

```

If you pass an argument whose type is not the same as the parameter's type, the argument will be promoted or demoted automatically. For instance, the argument in the following function call would be truncated, causing the value 4 to be passed to num:
displayValue(4.7)

Often, it's useful to pass several arguments into a function. Program 6-8 shows the definition of a function with three parameters.

\section*{Program 6-8}
```

// This program demonstrates a function with three parameters.
\#include <iostream>
using namespace std;
// Function Prototype
void showSum(int, int, int);
int main()
{
int value1, value2, value3;
// Get three integers.
cout << "Enter three integers and I will display ";
cout << "their sum: ";
cin >> value1 >> value2 >> value3;
// Cal1 showSum passing three arguments.
showSum(value1, value2, value3);
return 0;
}
|/**************************************************************
// Definition of function showSum.
// It uses three integer parameters. Their sum is displayed.*
//****************************************************************
void showSum(int num1, int num2, int num3)
{
cout << (num1 + num2 + num3) << end1;
}

```

\section*{Program Output with Example Input Shown in Bold}

Enter three integers and I will display their sum: 487 Enter 19

In the function header for showSum, the parameter list contains three variable definitions separated by commas:
```

void showSum(int num1, int num2, int num3)

```

WARNING! Each parameter variable in a parameter list must have a data type listed before its name. For example, a compiler error would occur if the parameter list for the showSum function were defined as shown in the following header:
void showSum(int num1, num2, num3) // Error!
A data type for all three of the parameter variables must be listed, as shown here:
void showSum(int num1, int num2, int num3) // Correct

In the function call in line 18 , the variables value1, value2, and value3 are passed as arguments:
```

showSum(value1, value2, value3);

```

When a function with multiple parameters is called, the arguments are passed to the parameters in order. This is illustrated in Figure 6-7.

Figure 6-7 Multiple arguments

The following function call will cause 5 to be passed into the num 1 parameter, 10 to be passed into num2, and 15 to be passed into num3:
```

showSum(5, 10, 15);

```

However, the following function call will cause 15 to be passed into the num1 parameter, 5 to be passed into num2, and 10 to be passed into num3:
```

showSum(15, 5, 10);

```

NOTE: The function prototype must list the data type of each parameter.

NOTE: Like all variables, parameters have a scope. The scope of a parameter is limited to the body of the function that uses it.

\subsection*{6.5 Passing Data by Value}

CONCEPT: When an argument is passed into a parameter, only a copy of the argument's value is passed. Changes to the parameter do not affect the original argument.

As you've seen in this chapter, parameters are special-purpose variables that are defined inside the parentheses of a function definition. They are separate and distinct from the arguments that are listed inside the parentheses of a function call. The values that are stored in the parameter variables are copies of the arguments. Normally, when a parameter's value is changed inside a function, it has no effect on the original argument. Program 6-9 demonstrates this concept.

\section*{Program 6-9}
```

// This program demonstrates that changes to a function parameter
// have no effect on the original argument.
\#include <iostream>
using namespace std;
// Function Prototype
void changeMe(int);
int main()
{
int number = 12;
// Display the value in number.
cout << "number is " << number << endl;
// Call changeMe, passing the value in number
// as an argument.
changeMe(number);
// Display the value in number again.
cout << "Now back in main again, the value of ";
cout << "number is " << number << endl;
return 0;
}
|/|************************************************************
// Definition of function changeMe.
// This function changes the value of the parameter myValue. *
//***************************************************************

```

30
```

void changeMe(int myValue)
{
// Change the value of myValue to 0.
myValue = 0;
// Display the value in myValue.
cout << "Now the value is " << myValue << endl;
}

```

\section*{Program Output}
number is 12
Now the value is 0
Now back in main again, the value of number is 12

Even though the parameter variable myValue is changed in the changeMe function, the argument number is not modified. The myValue variable contains only a copy of the number variable.

The changeMe function does not have access to the original argument. When only a copy of an argument is passed to a function, it is said to be passed by value. This is because the function receives a copy of the argument's value and does not have access to the original argument.

Figure 6-8 illustrates that a parameter variable's storage location in memory is separate from that of the original argument.

Figure 6-8 The argument and the parameter are separate
Original argument (in its memory location)

Function parameter (in its memory location)
```

1 2

```

NOTE: Later in this chapter, you will learn ways to give a function access to its original arguments.

\subsection*{6.6 Focus on Software Engineering: Using Functions in a Menu-Driven Program}

CONCEPT: Functions are ideal for use in menu-driven programs. When the user selects an item from a menu, the program can call the appropriate function.

In Chapters 4 and 5 , you saw a menu-driven program that calculates the charges for a health club membership. Program 6-10 shows the program redesigned as a modular program. A modular program is broken up into functions that perform specific tasks.

\section*{Program 6-10}
```

// This is a menu-driven program that makes a function call
// for each selection the user makes.
\#include <iostream>
\#include <iomanip>
using namespace std;
// Function prototypes
void showMenu();
void showFees(double, int);
int main()
{
int choice; // To hold a menu choice
int months; // To hold a number of months
// Constants for the menu choices
const int ADULT_CHOICE = 1,
CHILD_CHOICE = 2,
SENIOR_CHOICE = 3,
QUIT_CHOICE = 4;
// Constants for membership rates
const double ADULT = 40.0,
CHILD = 20.0;
SENIOR = 30.0,
// Set up numeric output formatting.
cout << fixed << showpoint << setprecision(2);
do
{
// Display the menu and get the user's choice.
showMenu();
cin >> choice;
// Validate the menu selection.
while (choice < ADULT_CHOICE || choice > QUIT_CHOICE)
{

```
```

            cout << "Please enter a valid menu choice: ";
                    cin >> choice;
            }
            // If the user does not want to quit, proceed.
            if (choice != QUIT_CHOICE)
            {
                // Get the number of months.
                cout << "For how many months? ";
                cin >> months;
                // Display the membership fees.
                switch (choice)
                {
                    case ADULT_CHOICE:
                        showFees(ADULT, months);
                            break;
                case CHILD_CHOICE:
                    showFees(CHILD, months);
                            break;
                case SENIOR_CHOICE:
                    showFees(SENIOR, months);
                }
            }
        } while (choice != QUIT_CHOICE);
        return 0;
    }
//********************************************************************
// Definition of function showMenu which displays the menu.
//*******************************************************************
void showMenu()
{
cout << "\n\t\tHealth Club Membership Menu\n\n"
<< "1. Standard Adult Membership\n"
<< "2. Child Membership\n"
<< "3. Senior Citizen Membership\n"
<< "4. Quit the Program\n\n"
<< "Enter your choice: ";
}
//***********************************************************************
// Definition of function showFees. The memberRate parameter holds*
// the monthly membership rate and the months parameter holds the *
// number of months. The function displays the total charges.
//***********************************************************************
void showFees(double memberRate, int months)
{
cout << "The total charges are \$"
<< (memberRate * months) << endl;
}

```
```

Program 6-10
(continued)
Program Output with Example Input Shown in Bold
Health Club Membership Menu

1. Standard Adult Membership
2. Child Membership
3. Senior Citizen Membership
4. Quit the Program
Enter your choice: 1 Enter
For how many months? 12 Enter
The total charges are \$480.00
Health Club Membership Menu
5. Standard Adult Membership
6. Child Membership
7. Senior Citizen Membership
8. Quit the Program
Enter your choice: 4 Enter
```

Let's take a closer look at this program. First notice the showMenu function in lines 71 through 79. This function displays the menu and is called from the main function in line 33.

The showFees function appears in lines 87 through 91. Its purpose is to display the total fees for a membership lasting a specified number of months. The function accepts two arguments: the monthly membership fee (a double) and the number of months of membership (an int). The function uses these values to calculate and display the total charges. For example, if we wanted the function to display the fees for an adult membership lasting 6 months, we would pass the ADULT constant as the first argument, and 6 as the second argument.

The showFees function is called from three different locations in the switch statement, which is in the main function. The first location is line 54 . This statement is executed when the user has selected item 1, standard adult membership, from the menu. The showFees function is called with the ADULT constant and the months variable passed as arguments. The second location is line 57 . This statement is executed when the user has selected item 2, child membership, from the menu. The showFees function is called in this line with the CHILD constant and the months variable passed as arguments. The third location is line 60. This statement is executed when the user has selected item 3, senior citizen membership, from the menu. The showFees function is called with the SENIOR constant and the months variable passed as arguments. Each time the showFees function is called, it displays the total membership fees for the specified type of membership, for the specified number of months.

\section*{Checkpoint}
6.5 Indicate which of the following is the function prototype, the function header, and the function call:
```

void showNum(double num)
void showNum(doub1e);
showNum(45.67);

```
6.6 Write a function named timesTen. The function should have an integer parameter named number. When timesTen is called, it should display the product of number times ten. (Note: Just write the function. Do not write a complete program.)
6.7 Write a function prototype for the timesTen function you wrote in Question 6.6.
6.8 What is the output of the following program?
```

\#include <iostream>
using namespace std;
void showDouble(int); // Function prototype
int main()
{
int num;
for (num = 0; num < 10; num++)
showDouble(num);
return 0;
}
// Definition of function showDouble.
void showDouble(int value)
{
cout << value << "\t" << (value * 2) << endl;
}

```
6.9 What is the output of the following program?
```

\#include <iostream>
using namespace std;
void func1(double, int); // Function prototype
int main()
{
int x = 0;
double y = 1.5;
cout << x << " " << y << endl;
func1(y, x);
cout << x << " " << y << endl;
return 0;
}

```
```

void func1(double a, int b)
{
cout << a << " " << b << endl;
a = 0.0;
b = 10;
cout << a << " " << b << endl;
}

```
6.10 The following program skeleton asks for the number of hours you've worked and your hourly pay rate. It then calculates and displays your wages. The function showDollars, which you are to write, formats the output of the wages.
```

\#include <iostream>
using namespace std;
void showDollars(double); // Function prototype
int main()
{
double payRate, hoursWorked, wages;
cout << "How many hours have you worked? "
cin >> hoursWorked;
cout << "What is your hourly pay rate? ";
cin >> payRate;
wages = hoursWorked * payRate;
showDollars(wages);
return 0;
}
// You must write the definition of the function showDollars
// here. It should take one parameter of the type double.
// The function should display the message "Your wages are \$"
// followed by the value of the parameter. It should be displayed
// with 2 places of precision after the decimal point, in fixed
// notation, and the decimal point should always display.

```

\subsection*{6.7 The return Statement}

CONCEPT: The return statement causes a function to end immediately.
When the last statement in a void function has finished executing, the function terminates and the program returns to the statement following the function call. It's possible, however, to force a function to return before the last statement has been executed. When the return statement is encountered, the function immediately terminates and control of the program returns to the statement that called the function. This is demonstrated in Program 6-11. The function divide shows the quotient of arg1 divided by arg2. If arg2 is set to zero, the function returns.

\section*{Program 6-11}
```

// This program uses a function to perform division. If division
// by zero is detected, the function returns.
\#include <iostream>
using namespace std;
// Function prototype.
void divide(double, double);
int main()
{
doub1e num1, num2;
cout << "Enter two numbers and I will divide the first\n";
cout << "number by the second number: ";
cin >> num1 >> num2;
divide(num1, num2);
return 0;
}
//************************************************************************
// Definition of function divide.
// Uses two parameters: arg1 and arg2. The function divides arg1 *
// by arg2 and shows the result. If arg2 is zero, however, the *
// function returns.
||*****************************************************************
void divide(doub1e arg1, double arg2)
{
if (arg2 == 0.0)
{
cout << "Sorry, I cannot divide by zero.\n";
return;
}
cout << "The quotient is " << (arg1 / arg2) << end1;
}

```

\section*{Program Output with Example Input Shown in Bold}

Enter two numbers and I will divide the first
number by the second number: 120 Enter
Sorry, I cannot divide by zero.

In the example running of the program, the user entered 12 and 0 as input. In line 16, the divide function was called, passing 12 into the arg1 parameter and 0 into the arg2 parameter. Inside the divide function, the if statement in line 29 executes. Because arg2 is equal to 0.0 , the code in lines 31 and 32 executes. When the return statement in line 32 executes, the divide function immediately ends. This means the cout statement in line 34 does not execute. The program resumes at line 17 in the main function.

\subsection*{6.8 Returning a Value from a Function}

CONCEPT: A function may send a value back to the part of the program that called the function.

You've seen that data may be passed into a function by way of parameter variables. Data may also be returned from a function, back to the statement that called it. Functions that return a value are appropriately known as value-returning functions.

The pow function, which you have already seen, is an example of a value-returning function. Here is an example:
```

double x;
x = pow(4.0, 2.0);

```

The second line in this code calls the pow function, passing 4.0 and 2.0 as arguments. The function calculates the value of 4.0 raised to the power of 2.0 and returns that value. The value, which is 16.0 , is assigned to the x variable by the \(=\) operator.
Although several arguments may be passed into a function, only one value may be returned from it. Think of a function as having multiple communication channels for receiving data (parameters), but only one channel for sending data (the return value). This is illustrated in Figure 6-9.

Figure 6-9 A function returns one value

NOTE: It is possible to return multiple values from a function, but they must be "packaged" in such a way that they are treated as a single value. This will be a topic in Chapter 11.

\section*{Defining a Value-Returning Function}

When you are writing a value-returning function, you must decide what type of value the function will return. This is because you must specify the data type of the return value in the function header and in the function prototype. Recall that a void function, which does not return a value, uses the key word void as its return type in the function header.

A value-returning function will use int, double, bool, or any other valid data type in its header. Here is an example of a function that returns an int value:
```

int sum(int num1, int num2)
{
int result;
result = num1 + num2;
return result;
}

```

The name of this function is sum. Notice in the function header the return type is int, as illustrated in Figure 6-10.

Figure 6-10 Function return type

This code defines a function named sum that accepts two int arguments. The arguments are passed into the parameter variables num1 and num2. Inside the function, a variable, result, is defined. Variables that are defined inside a function are called local variables. After the variable definition, the parameter variables num 1 and num 2 are added, and their sum is assigned to the result variable. The last statement in the function is
```

return result;

```

This statement causes the function to end, and it sends the value of the result variable back to the statement that called the function. A value-returning function must have a return statement written in the following general format:
```

return expression;

```

In the general format, expression is the value to be returned. It can be any expression that has a value, such as a variable, literal, or mathematical expression. The value of the expression is converted to the data type that the function returns, and is sent back to the statement that called the function. In this case, the sum function returns the value in the result variable.

However, we could have eliminated the result variable and returned the expression num1 + num2, as shown in the following code:
```

int sum(int num1, int num2)
{
return num1 + num2;
}

```

When writing the prototype for a value-returning function, follow the same conventions we have covered earlier. Here is the prototype for the sum function:
```

int sum(int, int);

```

\section*{Calling a Value-Returning Function}

Program 6-12 shows an example of how to call the sum function.

\section*{Program 6-12}
```

// This program uses a function that returns a value.
\#include <iostream>
using namespace std;
// Function prototype
int sum(int, int);
int main()
{
int value1 = 20, // The first value
value2 = 40, // The second value
total; // To hold the total
// Call the sum function, passing the contents of
// value1 and value2 as arguments. Assign the return
// value to the total variable.
total = sum(value1, value2);
// Display the sum of the values.
cout << "The sum of " << value1 << " and "
<< value2 << " is " << total << endl;
return 0;
}
//****************************************************
// Definition of function sum. This function returns *
// the sum of its two parameters.
//****************************************************
int sum(int num1, int num2)
{
return num1 + num2;
}

```

\section*{Program Output}

The sum of 20 and 40 is 60

Here is the statement in line 17 that calls the sum function, passing value 1 and value 2 as arguments:
```

tota1 = sum(value1, value2);

```

This statement assigns the value returned by the sum function to the total variable. In this case, the function will return 60 . Figure 6-11 shows how the arguments are passed into the function, and how a value is passed back from the function.

Figure 6-11 A function's arguments and return value

When you call a value-returning function, you usually want to do something meaningful with the value it returns. Program 6-12 shows a function's return value being assigned to a variable. This is commonly how return values are used, but you can do many other things with them. For example, the following code shows a mathematical expression that uses a call to the sum function:
```

int x = 10, y = 15;
double average;
average = sum(x, y) / 2.0;

```

In the last statement, the sum function is called with x and y as its arguments. The function's return value, which is 25 , is divided by 2.0 . The result, 12.5 , is assigned to average. Here is another example:
```

int x = 10, y = 15;
cout << "The sum is " << sum(x, y) << endl;

```

This code sends the sum function's return value to cout so it can be displayed on the screen. The message "The sum is 25 " will be displayed.
Remember, a value-returning function returns a value of a specific data type. You can use the function's return value anywhere that you can use a regular value of the same data type. This means anywhere an int value can be used, a call to an int value-returning function can be used. Likewise, anywhere a double value can be used, a call to a double valuereturning function can be used. The same is true for all other data types.

Let's look at another example. Program 6-13, which calculates the area of a circle, has two functions in addition to main. One of the functions is named square, and it returns the square of any number passed to it as an argument. The square function is called in a mathematical statement. The program also has a function named getRadius, which prompts the user to enter the circle's radius. The value entered by the user is returned from the function.

\section*{Program 6-13}
```

1 // This program demonstrates two value-returning functions.
2 // The square function is called in a mathematical statement.
3 \#include <iostream>
4 \#include <iomanip>
5 using namespace std;

```

\section*{Program 6-13 (continued)}

6
//Function prototypes
double getRadius();
double square(double);
int main()
\{
    const double PI = 3.14159; // Constant for pi
    double radius; // To hold the circle's radius
    double area; \(/ /\) To hold the circle's area
    // Set the numeric output formatting.
    cout << fixed << showpoint << setprecision(2);
    // Get the radius of the circle.
    cout << "This program calculates the area of ";
    cout << "a circle. \n";
    radius = getRadius();
    // Calculate the area of the circle.
    area \(=P I\) * square(radius);
    // Display the area.
    cout << "The area is " << area << endl;
    return 0;
\}

// Definition of function getRadius.
// This function asks the user to enter the radius of
// the circle and then returns that number as a double.*
l।***********************
double getRadius()
\{
        double rad;
        cout << "Enter the radius of the circle: ";
        cin >> rad;
        return rad;
\}

// Definition of function square.
// This function accepts a double argument and returns *
// the square of the argument as a double.

double square(double number)
```

55 {
return number * number;
}

```

\section*{Program Output with Example Input Shown in Bold}

This program calculates the area of a circle. Enter the radius of the circle: 10 Enter
The area is 314.16

First, look at the getRadius function defined in lines 39 through 46. The purpose of the function is to prompt the user to enter the radius of a circle. In line 41 , the function defines a local variable, rad. Lines 43 and 44 prompt the user to enter the circle's radius, which is stored in the rad variable. In line 45 , the value of the rad value is returned. The getRadius function is called in the main function, in line 23. The value that is returned from the function is assigned to the radius variable.

Next, look at the square function, which is defined in lines 54 through 57. When the function is called, a double argument is passed to it. The function stores the argument in the number parameter. The return statement in line 56 returns the value of the expression number * number, which is the square of the number parameter. The square function is called in the main function, in line 26 , with the value of radius passed as an argument. The function will return the square of the radius variable, and that value will be used in the mathematical expression.

Assuming the user has entered 10 as the radius, and this value is passed as an argument to the square function, the square function will return the value 100. Figure 6-12 illustrates how the value 100 is passed back to the mathematical expression in line 26 . The value 100 will then be used in the mathematical expression.

Figure 6-12 The square function

Functions can return values of any type. Both the getRadius and square functions in Program 6-13 return a double. The sum function you saw in Program 6-12 returned an int. When a statement calls a value-returning function, it should properly handle the return value. For example, if you assign the return value of the square function to a variable, the variable should be a double. If the return value of the function has a fractional portion and you assign it to an int variable, the value will be truncated.

\section*{In the Spotlight:}

\section*{Using Functions}

Your friend Michael runs a catering company. Some of the ingredients that his recipes require are measured in cups. When he goes to the grocery store to buy those ingredients, however, they are sold only by the fluid ounce. He has asked you to write a simple program that converts cups to fluid ounces.

You design the following algorithm:
1. Display an introductory screen that explains what the program does.
2. Get the number of cups.
3. Convert the number of cups to fluid ounces and display the result.

This algorithm lists the top level of tasks that the program needs to perform and becomes the basis of the program's main function. The hierarchy chart shown in Figure 6-13 shows how the program will be broken down into functions.

Figure 6-13 Hierarchy chart for the program

As shown in the hierarchy chart, the main function will call three other functions. Here are summaries of those functions:
- showIntro-This function will display a message on the screen that explains what the program does.
- getCups-This function will prompt the user to enter the number of cups, then will return that value as a double.
- cupsToOunces-This function will accept the number of cups as an argument, then return an equivalent number of fluid ounces as a double.

Program 6-14 shows the code for the program.

\section*{Program 6-14}
```

// This program converts cups to fluid ounces.
\#include <iostream>
\#include <iomanip>
using namespace std;

```
```

// Function prototypes
void showIntro();
double getCups();
double cupsToOunces(double);
int main()
{
// Variables for the cups and ounces.
double cups, ounces;
// Set up numeric output formatting.
cout << fixed << showpoint << setprecision(1);
// Display an intro screen.
showIntro();
// Get the number of cups.
cups = getCups();
// Convert cups to fluid ounces.
ounces = cupsToOunces(cups);
// Display the number of ounces.
cout << cups << " cups equals "
<< ounces << " ounces.\n";
return 0;
}
//*******************************************
// The showIntro function displays an
// introductory screen
|/*******************************************
void showIntro()
{
cout << "This program converts measurements\n"
<< "in cups to fluid ounces. For your\n"
<< "reference the formula is:\n"
<< " 1 cup = 8 fluid ounces\n\n";
}
|/**********************************************
// The getCups function prompts the user
// to enter the number of cups and then *
// returns that value as a double. *
//********************************************
double getCups()

```
```

Program 6-14 (continued)
55 {
56 double numCups;
5 7
58
59
cout << "Enter the number of cups: ";
cin >> numCups;
return numCups;
}
//********************************************
// The cupsToOunces function accepts a
// number of cups as an argument and
// returns the equivalent number of fluid
// ounces as a double.
//********************************************
doub1e cupsToOunces(double numCups)
{
return numCups * 8.0;
}

```

\section*{Program Output with Example Input Shown in Bold}

This program converts measurements
in cups to fluid ounces. For your
reference the formula is:
1 cup \(=8\) fluid ounces
Enter the number of cups: 2 Enter
2.0 cups equals 16.0 ounces.

\subsection*{6.9 Returning a Boolean Value}

CONCEPT: Functions may return true or false values.
Frequently, there is a need for a function that tests an argument and returns a true or false value indicating whether or not a condition exists. Such a function would return a bool value. For example, the following function accepts an int argument and returns true if the argument is within the range of 1 through 100 , or false otherwise:
```

bool isValid(int number)
{
bool status;
if (number >= 1 \&\& number <= 100)
status = true;
else
status = false;
return status;
}

```

The following code shows an \(\mathrm{if} / \mathrm{e} 1 \mathrm{se}\) statement that uses a call to the function:
```

int value = 20;
if (isValid(value))
cout << "The value is within range.\n";
else
cout << "The value is out of range.\n";

```

When this code executes, the message "The value is within range." will be displayed.
Program 6-15 shows another example. This program has a function named isEven which returns true if its argument is an even number. Otherwise, the function returns false.

\section*{Program 6-15}
```

// This program uses a function that returns true or false.
\#include <iostream>
using namespace std;
// Function prototype
bool isEven(int);
int main()
{
int val;
// Get a number from the user.
cout << "Enter an integer and I will tell you ";
cout << "if it is even or odd: ";
cin >> val;
// Indicate whether it is even or odd.
if (isEven(val))
cout << val << " is even.\n";
else
cout << val << " is odd.\n";
return 0;
}
//***************************************************************
// integer argument and tests it to be even or odd. The function *
// returns true if the argument is even or false if the argument *
// is odd. The return value is a bool.
/|*****************************************************************
bool isEven(int number)
{
bool status;
if (number % 2 == 0)
status = true; // The number is even if there is no remainder.
else

```
```

Program 6-15 (continued)
39 status = false; // Otherwise, the number is odd.
40 return status;
41 }

```

\section*{Program Output with Example Input Shown in Bold}

Enter an integer and I will tell you if it is even or odd: 5 Enter 5 is odd.

The isEven function is called in line 18, in the following statement:
if (isEven(va1))
When the if statement executes, isEven is called with val as its argument. If val is even, isEven returns true; otherwise, it returns false.

\section*{Checkpoint}
6.11 How many return values may a function have?
6.12 Write a header for a function named distance. The function should return a double and have two double parameters: rate and time.
6.13 Write a header for a function named days. The function should return an int and have three int parameters: years, months, and weeks.
6.14 Write a header for a function named getKey. The function should return a char and use no parameters.
6.15 Write a header for a function named lightYears. The function should return a long and have one long parameter: miles.

\subsection*{6.10 Local and Global Variables}

CONCEPT: A local variable is defined inside a function and is not accessible outside the function. A global variable is defined outside all functions and is accessible to all functions in its scope.

\section*{Local Variables}

Variables defined inside a function are local to that function. They are hidden from the statements in other functions, which normally cannot access them. Program 6-16 shows that because the variables defined in a function are hidden, other functions may have separate, distinct variables with the same name.

\section*{Program 6-16}
// This program shows that variables defined in a function
// are hidden from other functions.
\#include <iostream>
using namespace std;
```

void anotherFunction(); // Function prototype
int main()
{
int num = 1; // Local variable
cout << "In main, num is " << num << endl;
anotherFunction();
cout << "Back in main, num is " << num << endl;
return 0;
}
//******************************************************
// Definition of anotherFunction *
// It has a local variable, num, whose initial value *
// is displayed.
/|*******************************************************
void anotherFunction()
{
int num = 20; // Local variable
cout << "In anotherFunction, num is " << num << endl;
}

```

\section*{Program Output}

In main, num is 1
In anotherFunction, num is 20
Back in main, num is 1

Even though there are two variables named num, the program can only "see" one of them at a time because they are in different functions. When the program is executing in main, the num variable defined in main is visible. When anotherFunction is called, however, only variables defined inside it are visible, so the num variable in main is hidden. Figure 6-14 illustrates the closed nature of the two functions. The boxes represent the scope of the variables.

Figure 6-14 Visibility of local variables

\section*{Local Variable Lifetime}

A function's local variables exist only while the function is executing. This is known as the lifetime of a local variable. When the function begins, its local variables and its parameter variables are created in memory, and when the function ends, the local variables and parameter variables are destroyed. This means that any value stored in a local variable is lost between calls to the function in which the variable is declared.

\section*{Initializing Local Variables with Parameter Values}

It is possible to use a parameter variable to initialize a local variable. Sometimes this simplifies the code in a function. For example, recall the first version of the sum function we discussed earlier:
```

int sum(int num1, int num2)
{
int result;
result = num1 + num2;
return result;
}

```

In the body of the function, the result variable is defined and then a separate assignment statement assigns num1 + num2 to result. We can combine these statements into one, as shown in the following modified version of the function.
```

int sum(int num1, int num2)
{
int result = num1 + num2;
return result;
}

```

Because the scope of a parameter variable is the entire function in which it is declared, we can use parameter variables to initialize local variables.

\section*{Global Variables}

A global variable is any variable defined outside all the functions in a program. The scope of a global variable is the portion of the program from the variable definition to the end. This means a global variable can be accessed by all functions that are defined after the global variable is defined. Program 6-17 shows two functions, main and anotherFunction, that access the same global variable, num.

\section*{Program 6-17}
// This program shows that a global variable is visible
// to all the functions that appear in a program after
// the variable's declaration.
\#include <iostream>
```

using namespace std;

```
void anotherFunction(); // Function prototype
int num \(=2 ; \quad\) // Global variable
int main()
```

{
cout << "In main, num is " << num << endl;
anotherFunction();
cout << "Back in main, num is " << num << endl;
return 0;
}
/|*****************************************************
// Definition of anotherFunction*
// This function changes the value of the *
// global variable num. *
//*******************************************************
void anotherFunction()
{
cout << "In anotherFunction, num is " << num << endl;
num = 50;
cout << "But, it is now changed to " << num << endl;
}

```

\section*{Program Output}

In main, num is 2
In anotherFunction, num is 2
But, it is now changed to 50
Back in main, num is 50
In Program 6-17, num is defined outside of all the functions. Because its definition appears before the definitions of main and anotherFunction, both functions have access to it.

Unless you explicitly initialize numeric global variables, they are automatically initialized to zero. Global character variables are initialized to NULL.* The variable globalNum in Program 6-18 is never set to any value by a statement, but because it is global, it is automatically set to zero.

\section*{Program 6-18}
```

// This program has an uninitialized global variable.
\#include <iostream>
using namespace std;
int globalNum; // Global variable, automatically set to zero
int main()
{
cout << "globalNum is " << globalNum << endl;
return 0;
}

```

\section*{Program Output}
globalnum is 0

\footnotetext{
*The NULL character is stored as ASCII code 0 .
}

Now that you've had a basic introduction to global variables, I must warn you to restrict your use of them. When beginning students first learn to write programs with multiple functions, they are sometimes tempted to make all their variables global. This is usually because global variables can be accessed by any function in the program without being passed as arguments. Although this approach might make a program easier to create, it usually causes problems later. The reasons are as follows:
- Global variables make debugging difficult. Any statement in a program can change the value of a global variable. If you find that the wrong value is being stored in a global variable, you have to track down every statement that accesses it to determine where the bad value is coming from. In a program with thousands of lines of code, this can be difficult.
- Functions that use global variables are usually dependent on those variables. If you want to use such a function in a different program, most likely you will have to redesign it so it does not rely on the global variable.
- Global variables make a program hard to understand. A global variable can be modified by any statement in the program. If you are to understand any part of the program that uses a global variable, you have to be aware of all the other parts of the program that access the global variable.

Because of this, you should not use global variables for the conventional purposes of storing, manipulating, and retrieving data. In most cases, you should declare variables locally and pass them as arguments to the functions that need to access them.

\section*{Global Constants}

Although you should try to avoid the use of global variables, it is generally permissible to use global constants in a program. A global constant is a named constant that is available to every function in a program. Because a global constant's value cannot be changed during the program's execution, you do not have to worry about the potential hazards that are associated with the use of global variables.

Global constants are typically used to represent unchanging values that are needed throughout a program. For example, suppose a banking program uses a named constant to represent an interest rate. If the interest rate is used in several functions, it is easier to create a global constant, rather than a local named constant in each function. This also simplifies maintenance. If the interest rate changes, only the declaration of the global constant has to be changed, instead of several local declarations.

Program 6-19 shows an example of how global constants might be used. The program calculates an employee's gross pay, including overtime. In addition to main, this program has two functions: getBasePay and getOvertimePay. The getBasePay function accepts the number of hours worked and returns the amount of pay for the non-overtime hours. The getOvertimePay function accepts the number of hours worked and returns the amount of pay for the overtime hours, if any.

\section*{Program 6-19}
// This program calculates gross pay. \#include <iostream>
\#include <iomanip>
```

using namespace std;
// Global constants
const double PAY_RATE = 22.55; // Hour1y pay rate
const double BASE_HOURS = 40.0; // Max non-overtime hours
const double OT_MULTIPLIER = 1.5; // Overtime multiplier
// Function prototypes
double getBasePay(doub1e);
doub1e getOvertimePay(doub1e);
int main()
{
double hours, // Hours worked
basePay, // Base pay
overtime = 0.0, /l Overtime pay
totalPay; // Total pay
// Get the number of hours worked.
cout << "How many hours did you work? ";
cin >> hours;
// Get the amount of base pay.
basePay = getBasePay(hours);
// Get overtime pay, if any.
if (hours > BASE_HOURS)
overtime = getOvertimePay(hours);
// Calculate the total pay.
totalPay = basePay + overtime;
// Set up numeric output formatting.
cout << setprecision(2) << fixed << showpoint;
// Display the pay.
cout << "Base pay: \$" << basePay << endl
<< "Overtime pay \$" << overtime << endl
<< "Total pay \$" << totalPay << endl;
return 0;
}
//***************************************************
// The getBasePay function accepts the number of
// hours worked as an argument and returns the *
// employee's pay for non-overtime hours. *
|/*******************************************************
doub1e getBasePay(doub1e hoursWorked)
{
double basePay; // To hold base pay

```
```

Program 6-19 (continued)
// Determine base pay.
if (hoursWorked > BASE_HOURS)
basePay = BASE_HOURS * PAY_RATE;
else
basePay = hoursWorked * PAY_RATE;
return basePay;
}
//***************************************************
// The getOvertimePay function accepts the number *
// of hours worked as an argument and returns the *
// employee's overtime pay.
//*************************************************
double getOvertimePay(double hoursWorked)
{
double overtimePay; // To hold overtime pay
// Determine overtime pay.
if (hoursWorked > BASE_HOURS)
{
overtimePay = (hoursWorked - BASE_HOURS) *
PAY_RATE * OT_MULTIPLIER;
}
else
overtimePay = 0.0;
return overtimePay;
}

```

\section*{Program Output with Example Input Shown in Bold}

How many hours did you work? 48 Enter
Base pay: \$902.00
Overtime pay: \$270.60
Total pay: \$1172.60

Let's take a closer look at the program. Three global constants are defined in lines 7, 8, and 9 . The PAY_RATE constant is set to the employee's hourly pay rate, which is 22.55 . The BASE_HOURS constant is set to 40, which is the number of hours an employee can work in a week without getting paid overtime. The OT_MULTIPLIER constant is set to 1.5 , which is the pay rate multiplier for overtime hours. This means that the employee's hourly pay rate is multiplied by 1.5 for all overtime hours.
Because these constants are global and are defined before all of the functions in the program, all the functions may access them. For example, the getBasePay function accesses the BASE_HOURS constant in lines 57 and 58 and accesses the PAY_RATE constant in lines 58 and 60. The getOvertimePay function accesses the BASE_HOURS constant in lines 76 and 78 , the PAY_RATE constant in line 79 , and the OT_MULTIPLIER constant in line 79.

\section*{Local and Global Variables with the Same Name}

You cannot have two local variables with the same name in the same function. This applies to parameter variables as well. A parameter variable is, in essence, a local variable. So, you cannot give a parameter variable and a local variable in the same function the same name.

However, you can have a local variable or a parameter variable with the same name as a global variable, or a global constant. When you do, the name of the local or parameter variable shadows the name of the global variable or global constant. This means that the global variable or constant's name is hidden by the name of the local or parameter variable. For example, look at Program 6-20. This program has a global constant named BIRDS, set to 500 . The california function has a local constant named BIRDS, set to 10000 .

\section*{Program 6-20}
```

// This program demonstrates how a local variable
// can shadow the name of a global constant.
\#include <iostream>
using namespace std;
// Global constant.
const int BIRDS = 500;
// Function prototype
void california();
int main()
{
cout << "In main there are " << BIRDS
<< " birds.\n";
california();
return 0;
}
|/|********************************************
// california function
|/|**********************************************
void california()
{
const int BIRDS = 10000;
cout << "In california there are " << BIRDS
<< " birds.\n";
}

```

\section*{Program Output}

In main there are 500 birds.
In california there are 10000 birds.
When the program is executing in the main function, the global constant BIRDS, which is set to 500 , is visible. The cout statement in lines 14 and 15 displays "In main there are 500 birds." (My apologies to folks living in Maine for the difference in spelling.)

When the program is executing in the california function, however, the local constant BIRDS shadows the global constant BIRDS. When the california function accesses BIRDS, it accesses the local constant. That is why the cout statement in lines 27 and 28 displays "In california there are 10000 birds."

\subsection*{6.11 Static Local Variables}

If a function is called more than once in a program, the values stored in the function's local variables do not persist between function calls. This is because the local variables are destroyed when the function terminates, and are then re-created when the function starts again. This is shown in Program 6-21.

\section*{Program 6-21}
```

// This program shows that local variables do not retain
// their values between function calls.
\#include <iostream>
using namespace std;
// Function prototype
void showLocal();
int main()
{
showLocal();
showLocal();
return 0;
}
//**********************************************************
// Definition of function showLocal.
// The initial value of localNum, which is 5, is displayed.
// The value of localNum is then changed to 99 before the
// function returns.
//***********************************************************
void showLocal()
{
int localNum = 5; // Local variable
cout << "localNum is " << localNum << endl;
localNum = 99;
}

```

\section*{Program Output}
```

localNum is 5
localNum is 5

```

Even though in line 28, the last statement in the showLocal function stores 99 in 1ocalNum, the variable is destroyed when the function returns. The next time the function is called, localNum is re-created and initialized to 5 again.

Sometimes it's desirable for a program to "remember" what value is stored in a local variable between function calls. This can be accomplished by making the variable static. Static local variables are not destroyed when a function returns. They exist for the lifetime of the program, even though their scope is only the function in which they are defined. Program 6-22 demonstrates some characteristics of static local variables:

\section*{Program 6-22}
```

// This program uses a static local variable.
\#include <iostream>
using namespace std;
void showStatic(); // Function prototype
int main()
{
// Call the showStatic function five times.
for (int count = 0; count < 5; count++)
showStatic();
return 0;
}
//*******************************************************************
// Definition of function showStatic. *
// statNum is a static local variable. Its value is displayed *
// and then incremented just before the function returns. *
//****************************************************************
void showStatic()
{
static int statNum;
cout << "statNum is " << statNum << endl;
statNum++;
}

```

\section*{Program Output}
```

statNum is 0
statNum is 1
statNum is 2
statNum is 3
statNum is 4

```

In line 26 of Program 6-22, statNum is incremented in the showStatic function, and it retains its value between each function call. Notice even though statNum is not explicitly initialized, it starts at zero. Like global variables, all static local variables are initialized to zero by default. (Of course, you can provide your own initialization value, if necessary.)

If you do provide an initialization value for a static local variable, the initialization only occurs once. This is because initialization normally happens when the variable is created, and static local variables are only created once during the running of a program. Program 6-23, which is a slight modification of Program 6-22, illustrates this point.

\section*{Program 6-23}
```

// This program shows that a static local variable is only
// initialized once.
\#include <iostream>
using namespace std;
void showStatic(); // Function prototype
int main()
{
// Call the showStatic function five times.
for (int count = 0; count < 5; count++)
showStatic();
return 0;
}
/|****************************************************************
// Definition of function showStatic.
// statNum is a static local variable. Its value is displayed *
// and then incremented just before the function returns. *
/|*************************************************************
void showStatic()
{
static int statNum = 5;
cout << "statNum is " << statNum << endl;
statNum++;
}

```

\section*{Program Output}
statNum is 5
statNum is 6
statNum is 7
statNum is 8
statNum is 9
Even though the statement that defines statNum in line 24 initializes it to 5 , the initialization does not happen each time the function is called. If it did, the variable would not be able to retain its value between function calls.

\section*{Checkpoint}
6.16 What is the difference between a static local variable and a global variable?
6.17 What is the output of the following program?
```

\#include <iostream>
using namespace std;
void myFunc(); // Function prototype
int main()
{

```
```

    int var = 100;
    cout << var << endl;
    myFunc();
    cout << var << endl;
    return 0;
    }
// Definition of function myFunc
void myFunc()
{
int var = 50;
cout << var << endl;
}

```
6.18 What is the output of the following program?
```

\#include <iostream>
using namespace std;
void showVar(); // Function prototype
int main()
{
for (int count = 0; count < 10; count++)
showVar();
return 0;
}
// Definition of function showVar
void showVar()
{
static int var = 10;
cout << var << endl;
var++;
}

```

\subsection*{6.12 Default Arguments}

CONCEPT: Default arguments are passed to parameters automatically if no argument is provided in the function call.

It's possible to assign default arguments to function parameters. A default argument is passed to the parameter when the actual argument is left out of the function call. The default arguments are usually listed in the function prototype. Here is an example:
```

void showArea(double = 20.0, double = 10.0);

```

Default arguments are literal values or constants with an \(=\) operator in front of them, appearing after the data types listed in a function prototype. Since parameter names are optional in function prototypes, the example prototype could also be declared as
```

void showArea(double length = 20.0, double width = 10.0);

```

In both example prototypes, the function showArea has two double parameters. The first is assigned the default argument 20.0, and the second is assigned the default argument 10.0. Here is the definition of the function:
```

void showArea(double length, double width)
{
double area = length * width;
cout << "The area is " << area << endl;
}

```

The default argument for length is 20.0 , and the default argument for width is 10.0 . Because both parameters have default arguments, they may optionally be omitted in the function call, as shown here:
showArea();
In this function call, both default arguments will be passed to the parameters. The parameter length will take the value 20.0 and width will take the value 10.0. The output of the function will be

The area is 200
The default arguments are only used when the actual arguments are omitted from the function call. In the call below, the first argument is specified, but the second is omitted:
showArea(12.0);
The value 12.0 will be passed to length, while the default value 10.0 will be passed to width. The output of the function will be

The area is 120
Of course, all the default arguments may be overridden. In the function call below, arguments are supplied for both parameters:
```

showArea(12.0, 5.5);

```

The output of the function call above will be
The area is 66

NOTE: If a function does not have a prototype, default arguments may be specified in the function header. The showArea function could be defined as follows:
```

void showArea(double length = 20.0, double width = 10.0)
{
double area = length * width;
cout << "The area is " << area << endl;
}

```

WARNING! A function's default arguments should be assigned in the earliest occurrence of the function name. This will usually be the function prototype.

Program 6-24 uses a function that displays asterisks on the screen. Arguments are passed to the function specifying how many columns and rows of asterisks to display. Default arguments are provided to display one row of 10 asterisks.

\section*{Program 6-24}
```

// This program demonstrates default function arguments.
\#include <iostream>
using namespace std;
// Function prototype with default arguments
void displayStars(int = 10, int = 1);
int main()
{
displayStars(); // Use default values for cols and rows.
cout << endl;
displayStars(5); // Use default value for rows.
cout << endl;
displayStars(7, 3); // Use 7 for cols and 3 for rows.
return 0;
}
//**************************************************************
// Definition of function displayStars.
// The default argument for cols is 10 and for rows is 1.*
// This function displays a square made of asterisks
//**********************************************************
void displayStars(int cols, int rows)
{
// Nested loop. The outer loop controls the rows
// and the inner loop controls the columns.
for (int down = 0; down < rows; down++)
{
for (int across = 0; across < cols; across++)
cout << "*";
cout << endl;
}
}

```

\section*{Program Output}
```

** * * * * * * * *

*     *         *             *                 * 

*******

```

Although C++'s default arguments are very convenient, they are not totally flexible in their use. When an argument is left out of a function call, all arguments that come after it must be left out as well. In the displayStars function in Program 6-24, it is not possible to omit the argument for cols without also omitting the argument for rows. For example, the following function call would be illegal:
```

displayStars(, 3); // Illegal function call.

```

It's possible for a function to have some parameters with default arguments, and some without. For example, in the following function (which displays an employee's gross pay), only the last parameter has a default argument:
```

// Function prototype
void calcPay(int empNum, double payRate, double hours = 40.0);
// Definition of function calcPay
void calcPay(int empNum, double payRate, double hours)
{
double wages;
wages = payRate * hours;
cout << fixed << showpoint << setprecision(2);
cout << "Gross pay for employee number ";
cout << empNum << " is " << wages << endl;
}

```

When calling this function, arguments must always be specified for the first two parameters (empNum and payRate) since they have no default arguments. Here are examples of valid calls:
```

calcPay(769, 15.75); // Use default arg for 40 hours
calcPay(142, 12.00, 20); // Specify number of hours

```

When a function uses a mixture of parameters with and without default arguments, the parameters with default arguments must be defined last. In the calcPay function, hours could not have been defined before either of the other parameters. The following prototypes are illegal:
```

// Illegal prototype
void calcPay(int empNum, double hours = 40.0, double payRate);
// Illegal prototype
void calcPay(double hours = 40.0, int empNum, double payRate);

```

Here is a summary of the important points about default arguments:
- The value of a default argument must be a literal value or a named constant.
- When an argument is left out of a function call (because it has a default value), all the arguments that come after it must be left out too.
- When a function has a mixture of parameters both with and without default arguments, the parameters with default arguments must be declared last.

\subsection*{6.13 Using Reference Variables as Parameters}

CONCEPT: When used as parameters, reference variables allow a function to access the parameter's original argument. Changes to the parameter are also made to the argument.

Earlier you saw that arguments are normally passed to a function by value, and that the function cannot change the source of the argument. C++ provides a special type of variable
called a reference variable that, when used as a function parameter, allows access to the original argument.

A reference variable is an alias for another variable. Any changes made to the reference variable are actually performed on the variable for which it is an alias. By using a reference variable as a parameter, a function may change a variable that is defined in another function.

Reference variables are defined like regular variables, except you place an ampersand (\&) in front of the name. For example, the following function definition makes the parameter refVar a reference variable:
```

void doubleNum(int \&refVar)
{
refVar *= 2;
}

```

NOTE: The variable refVar is called "a reference to an int."

This function doubles refVar by multiplying it by 2 . Since refVar is a reference variable, this action is actually performed on the variable that was passed to the function as an argument. When prototyping a function with a reference variable, be sure to include the ampersand after the data type. Here is the prototype for the doubleNum function:
```

void doubleNum(int \&);

```

NOTE: Some programmers prefer not to put a space between the data type and the ampersand. The following prototype is equivalent to the one above:
```

void doubleNum(int \&);

```

NOTE: The ampersand must appear in both the prototype and the header of any function that uses a reference variable as a parameter. It does not appear in the function call.

Program 6-25 demonstrates how the doubleNum function works.

\section*{Program 6-25}
```

// This program uses a reference variable as a function
// parameter.
\#include <iostream>
using namespace std;
// Function prototype. The parameter is a reference variable.
void doubleNum(int \&);

```
```

Program 6-25 (continued)
int main()
{
int value = 4;
cout << "In main, value is " << value << endl;
cout << "Now calling doubleNum..." << endl;
doubleNum(value);
cout << "Now back in main. value is " << value << endl;
return 0;
}
//************************************************************
// Definition of doubleNum. *
// The parameter refVar is a reference variable. The value *
// in refVar is doubled.
/|************************************************************
void doubleNum (int \&refVar)
{
refVar *= 2;
}

```

\section*{Program Output}

In main, value is 4
Now calling doubleNum...
Now back in main. value is 8

The parameter refVar in Program 6-25 "points" to the value variable in function main. When a program works with a reference variable, it is actually working with the variable it references, or to which it points. This is illustrated in Figure 6-15.

Figure 6-15 Reference variable

4

Recall that function arguments are normally passed by value, which means a copy of the argument's value is passed into the parameter variable. When a reference parameter is used, it is said that the argument is passed by reference.

Program 6-26 is a modification of Program 6-25. The function getNum has been added. The function asks the user to enter a number, which is stored in userNum. userNum is a reference to main's variable value.

\section*{Program 6-26}
```

// This program uses reference variables as function parameters.
\#include <iostream>
using namespace std;
// Function prototypes. Both functions use reference variables
// as parameters.
void doubleNum(int \&);
void getNum(int \&);
int main()
{
int value;
// Get a number and store it in value.
getNum(value);
// Double the number stored in value.
doubleNum(value);
// Display the resulting number.
cout << "That value doubled is " << value << endl;
return 0;
}
/|**************************************************************
// Definition of getNum
// The parameter userNum is a reference variable. The user is *
// asked to enter a number, which is stored in userNum.
//****************************************************************
void getNum(int \&userNum)
{
cout << "Enter a number: ";
cin >> userNum;
}
//**************************************************************
// Definition of doubleNum.
// The parameter refVar is a reference variable. The value *
// in refVar is doubled.
/|*************************************************************
void doubleNum (int \&refVar)
{
refVar *= 2;
}

```

\section*{Program Output with Example Input Shown in Bold}

Enter a number: 12 Enter
That value doubled is 24

NOTE: Only variables may be passed by reference. If you attempt to pass a nonvariable argument, such as a literal, a constant, or an expression, into a reference parameter, an error will result. Using the doubleNum function as an example, the following statements will generate an error:
```

doubleNum(5); // Error
doubleNum(userNum + 10); // Error

```

If a function uses more than one reference variable as a parameter, be sure to place the ampersand before each reference variable name. Here is the prototype and definition for a function that uses four reference variable parameters:
```

// Function prototype with four reference variables
// as parameters.
void addThree(int \&, int \&, int \&, int \&);
// Definition of addThree.
// All four parameters are reference variables.
void addThree(int \&sum, int \&num1, int \&num2, int \&num3)
{
cout << "Enter three integer values: ";
cin >> num1 >> num2 >> num3;
sum = num1 + num2 + num3;
}

```

WARNING! Don't get carried away with using reference variables as function parameters. Any time you allow a function to alter a variable that's outside the function, you are creating potential debugging problems. Reference variables should only be used as parameters when the situation requires them.

\section*{Checkpoint}
6.19 What kinds of values may be specified as default arguments?
6.20 Write the prototype and header for a function called compute. The function should have three parameters: an int, a double, and a long (not necessarily in that order). The int parameter should have a default argument of 5, and the 1 ong parameter should have a default argument of 65536. The doub1e parameter should not have a default argument.
6.21 Write the prototype and header for a function called calculate. The function should have three parameters: an int, a reference to a double, and a long (not necessarily in that order.) Only the int parameter should have a default argument, which is 47.
6.22 What is the output of the following program?
```

\#include <iostream>
using namespace std;
void test(int = 2, int = 4, int = 6);
int main()

```
```

{
test();
test(6);
test(3, 9);
test(1, 5, 7);
return 0;
}
void test (int first, int second, int third)
{
first += 3;
second += 6;
third += 9;
cout << first << " " << second << " " << third << endl;
}

```
6.23 The following program asks the user to enter two numbers. What is the output of the program if the user enters 12 and 14 ?
\#include <iostream>
using namespace std;
void func1(int \& , int \&);
void func2(int \&, int \&, int \&);
void func3(int, int, int);
int main()
\{
    int \(x=0, y=0, z=0 ;\)

    func1 (x, y);

    func2(x, y, z);
    cout \(\ll x\) << " " << y << " " << z << end1;
    func3(x, y, z);
    cout \(\ll x\) \(\ll\) " " << y << " " << z << end1;
    return 0;
\}
void func1(int \&a, int \&b)
\{
    cout << "Enter two numbers: ";
    cin >> a >> b;
\}
void func2(int \&a, int \&b, int \&c)
\{
        b++;
        c--;
        \(\mathrm{a}=\mathrm{b}+\mathrm{c}\);
\}
void func3(int \(a\), int \(b\), int \(c)\)
\{
        \(a=b-c ;\)
\}

\subsection*{6.14 Overloading Functions}

CONCEPT: Two or more functions may have the same name, as long as their parameter lists are different.

Sometimes, you will create two or more functions that perform the same operation, but use a different set of parameters or parameters of different data types. For instance, in Program 6-13 there is a square function that uses a double parameter. But, suppose you also wanted a square function that works exclusively with integers, accepting an int as its argument. Both functions would do the same thing: return the square of their argument. The only difference is the data type involved in the operation. If you were to use both these functions in the same program, you could assign a unique name to each function. For example, the function that squares an int might be named squareInt, and the one that squares a double might be named squareDouble. C++, however, allows you to overload functions. That means you may assign the same name to multiple functions, as long as their parameter lists are different. Program 6-27 uses two overloaded square functions.

\section*{Program 6-27}
// This program uses overloaded functions.
\#include <iostream>
\#include <iomanip>
```

using namespace std;

```
// Function prototypes
int square(int);
double square(double);
```

int main()

```
\{
        int userInt;
        double userFloat;
        // Get an int and a double.
        cout << fixed << showpoint << setprecision(2);
        cout << "Enter an integer and a floating-point value: ";
        cin >> userInt >> userFloat;
        // Display their squares.
        cout << "Here are their squares: ";
        cout << square(userInt) << " and " << square(userFloat);
        return 0;
\}

// Definition of overloaded function square. *
// This function uses an int parameter, number. It returns the *
// square of number as an int.

```

int square(int number)
{
return number * number;
}
//*****************************************************************
// Definition of overloaded function square.
// This function uses a double parameter, number. It returns *
// the square of number as a double.
/|*********************************************************************
double square(double number)
{
return number * number;
}

```

Program Output with Example Input Shown in Bold
Enter an integer and a floating-point value: 124.2 Enter
Here are their squares: 144 and 17.64

Here are the headers for the square functions used in Program 6-27:
```

int square(int number)
double square(double number)

```

In C++, each function has a signature. The function signature is the name of the function and the data types of the function's parameters in the proper order. The square functions in Program 6-27 would have the following signatures:
```

square(int)
square(doub1e)

```

When an overloaded function is called, C++ uses the function signature to distinguish it from other functions with the same name. In Program 6-27, when an int argument is passed to square, the version of the function that has an int parameter is called. Likewise, when a double argument is passed to square, the version with a double parameter is called.

Note the function's return value is not part of the signature. The following functions could not be used in the same program because their parameter lists aren't different:
```

int square(int number)
{
return number * number
}
double square(int number) // Wrong! Parameter lists must differ
{
return number * number
}

```

Overloading is also convenient when there are similar functions that use a different number of parameters. For example, consider a program with functions that return the sum of integers. One returns the sum of two integers, another returns the sum of three integers, and yet another returns the sum of four integers. Here are their function headers:
```

int sum(int num1, int num2)
int sum(int num1, int num2, int num3)
int sum(int num1, int num2, int num3, int num4)

```

Because the number of parameters is different in each, they all may be used in the same program. Program 6-28 is an example that uses two functions, each named calcWeek1yPay, to determine an employee's gross weekly pay. One version of the function uses an int and a double parameter, while the other version only uses a double parameter.

\section*{Program 6-28}
```

// This program demonstrates overloaded functions to calculate
// the gross weekly pay of hourly paid or salaried employees.
\#include <iostream>
\#include <iomanip>
using namespace std;
// Function prototypes
void getChoice(char \&);
double calcWeeklyPay(int, double);
double calcWeeklyPay(double);
int main()
{
char selection; // Menu selection
int worked; // Hours worked
double rate; // Hourly pay rate
double yearly; // Yearly salary
// Set numeric output formatting.
cout << fixed << showpoint << setprecision(2);
// Display the menu and get a selection.
cout << "Do you want to calculate the weekly pay of\n";
cout << "(H) an hourly paid employee, or \n";
cout << "(S) a salaried employee?\n";
getChoice(selection);
// Process the menu selection.
switch (selection)
{
// Hourly paid employee
case 'H' :
case 'h' : cout << "How many hours were worked? ";

```
```

                    cin >> worked;
                    cout << "What is the hourly pay rate? ";
                    cin >> rate;
                    cout << "The gross weekly pay is $";
                    cout << calcWeeklyPay(worked, rate) << endl;
                break;
            // Salaried employee
            case 'S' :
            case 's' : cout << "What is the annual salary? ";
                    cin >> yearly;
                    cout << "The gross weekly pay is $";
                    cout << calcWeeklyPay(yearly) << endl;
                    break;
    }
    return 0;
    }
//*****************************************************************
// Definition of function getChoice.
// The parameter letter is a reference to a char.
// This function asks the user for an H or an S and returns *
// the validated input.
|/*****************************************************************
void getChoice(char \& letter)
{
// Get the user's selection.
cout << "Enter your choice (H or S): ";
cin >> letter;
// Validate the selection.
while (letter != 'H' \&\& letter != 'h' \&\&
letter != 'S' \&\& letter != 's')
{
cout << "Please enter H or S: ";
cin >> letter;
}
}
//*************************************************************
// Definition of overloaded function calcWeeklyPay.
// This function calculates the gross weekly pay of
// an hourly paid employee. The parameter hours holds the
// number of hours worked. The parameter payRate holds the
// hourly pay rate. The function returns the weekly salary.
/|******************************************************************
double calcWeeklyPay(int hours, double payRate)
{

```
```

Program 6-28 (continued)
84 return hours * payRate;
85 }
86
87 l/*************************************************************
88 // Definition of overloaded function calcWeeklyPay. *
89 // This function calculates the gross weekly pay of *
90 // a salaried employee. The parameter holds the employee's *
91 // annual salary. The function returns the weekly salary. *
92 //
93
94 double calcWeek1yPay(doub1e annSalary)
95 {
96 return annSalary / 52;
97 }

```

\section*{Program Output with Example Input Shown in Bold}

Do you want to calculate the weekly pay of
(H) an hourly paid employee, or
(S) a salaried employee?

Enter your choice (H or S): H Enter
How many hours were worked? 40 Enter
What is the hourly pay rate? \(\mathbf{1 8 . 5 0}\) Enter
The gross weekly pay is \(\$ 740.00\)

\section*{Program Output with Example Input Shown in Bold}

Do you want to calculate the weekly pay of
(H) an hourly paid employee, or
(S) a salaried employee?

Enter your choice (H or S): S Enter
What is the annual salary? 68000.00 Enter
The gross weekly pay is \(\$ 1307.69\)

\subsection*{6.15 The exit() Function}

CONCEPT: The exit() function causes a program to terminate, regardless of which function or control mechanism is executing.

A C++ program stops executing when the return statement in function main is encountered. When other functions end, however, the program does not stop. Control of the program goes back to the place immediately following the function call. Sometimes rare circumstances make it necessary to terminate a program in a function other than main. To accomplish this, the exit function is used.

When the exit function is called, it causes the program to stop, regardless of which function contains the call. Program 6-29 demonstrates its use.

\section*{Program 6-29}
```

// This program shows how the exit function causes a program
// to stop executing.
\#include <iostream>
\#include <cstdlib> // Needed for the exit function
using namespace std;
void function(); // Function prototype
int main()
{
function();
return 0;
}
//**************************************************************
// This function simply demonstrates that exit can be used *
// to terminate a program from a function other than main. *
//************************************************************
void function()
{
cout << "This program terminates with the exit function.\n";
cout << "Bye!\n";
exit(0);
cout << "This message will never be displayed\n";
cout << "because the program has already terminated.\n";
}

```

\section*{Program Output}

This program terminates with the exit function.
Bye!
To use the exit function, you must include the <cstdlib> header file. Notice the function takes an integer argument. This argument is the exit code you wish the program to pass back to the computer's operating system. This code is sometimes used outside of the program to indicate whether the program ended successfully or as the result of a failure. In Program 6-29, the exit code zero is passed, which commonly indicates a successful exit. If you are unsure which code to use with the exit function, there are two named constants, EXIT_FAILURE and EXIT_SUCCESS, defined in <cstdlib> for you to use. The constant EXIT_FAILURE is defined as the termination code that commonly represents an unsuccessful exit under the current operating system. Here is an example of its use:
```

exit(EXIT_FAILURE);

```

The constant EXIT_SUCCESS is defined as the termination code that commonly represents a successful exit under the current operating system. Here is an example:
```

exit(EXIT_SUCCESS);

```

NOTE: Generally, the exit code is important only if you know it will be tested outside the program. If it is not used, just pass zero, or EXIT_SUCCESS.

WARNING! The exit () function unconditionally shuts down your program. Because it bypasses a program's normal logical flow, you should use it with caution.

\section*{Checkpoint}
6.24 What is the output of the following program?
```

\#include <iostream>
\#include <cstdlib>
using namespace std;
void showVals(double, double);
int main()
{
double x = 1.2, y = 4.5;
showVals(x, y);
return 0;
}
void showVa1s(doub1e p1, double p2)
{
cout << p1 << endl;
exit(0);
cout << p2 << end1;
}

```
6.25 What is the output of the following program?
```

\#include <iostream>
using namespace std;
int manip(int);
int manip(int, int);
int manip(int, double);
int main()
{
int x = 2, y= 4, z;
double a = 3.1;
z = manip(x) + manip(x, y) + manip(y, a);
cout << z << endl;
return 0;
}
int manip(int val)
{
return val + val * 2;
}
int manip(int val1, int val2)
{
return (val1 + val2) * 2;
}
int manip(int val1, double val2)
{
return val1 * static_cast<int>(val2);
}

```

\subsection*{6.16 Stulbs and Drivers}

Stubs and drivers are very helpful tools for testing and debugging programs that use functions. They allow you to test the individual functions in a program, in isolation from the parts of the program that call the functions.

A stub is a dummy function that is called instead of the actual function it represents. It usually displays a test message acknowledging that it was called, and nothing more. For example, if a stub were used for the showFees function in Program 6-10 (the modular health club membership program), it might look like this:
```

void showFees(double memberRate, int months)
{
cout << "The showFees function was called with "
<< "the following arguments:\n"
<< "memberRate: " << memberRate << endl
<< "months: " << months << endl;
}

```

The following is an example output of the program if it were run with the stub instead of the actual showFees function. (A version of the health club program using this stub function is available from Computer Science Portal at www.pearsonglobaleditions.com/gaddis. The program is named HealthClubWithStub.cpp.)

Health Club Membership Menu
1. Standard Adult Membership
2. Child Membership
3. Senior Citizen Membership
4. Quit the Program

Enter your choice: 1 Enter
For how many months? 4 Enter
The showFees function was called with the following arguments:
memberRate: 40.00
months: 4
Health Club Membership Menu
1. Standard Adult Membership
2. Child Membership
3. Senior Citizen Membership
4. Quit the Program

Enter your choice: 4 Enter
As you can see, by replacing an actual function with a stub, you can concentrate your testing efforts on the parts of the program that call the function. Primarily, the stub allows you to determine whether your program is calling a function when you expect it to, and to confirm that valid values are being passed to the function. If the stub represents a function that returns a value, then the stub should return a test value. This helps you confirm that the return value is being handled properly. When the parts of the program that call a function are debugged to your satisfaction, you can move on to testing and debugging the actual functions themselves. This is where drivers become useful.

A driver is a program that tests a function by simply calling it. If the function accepts arguments, the driver passes test data. If the function returns a value, the driver displays the return value on the screen. This allows you to see how the function performs in isolation from the rest of the program it will eventually be part of. Program 6-30 shows a driver for testing the showFees function in the health club membership program.

\section*{Program 6-30}
```

// This program is a driver for testing the showFees function.
\#include <iostream>
using namespace std;
// Prototype
void showFees(double, int);
int main()
{
// Constants for membership rates
const double ADULT = 40.0;
const double SENIOR = 30.0;
const double CHILD = 20.0;
// Perform a test for adult membership.
cout << "Testing an adult membership...\n"
<< "Calling the showFees function with arguments "
<< ADULT << " and 10.\n";
showFees(ADULT, 10);
// Perform a test for senior citizen membership.
cout << "\nTesting a senior citizen membership...\n"
<< "Calling the showFees function with arguments "
<< SENIOR << " and 10.\n";
showFees(SENIOR, 10);
// Perform a test for child membership.
cout << "\nTesting a child membership...\n"
<< "Calling the showFees function with arguments "
<< CHILD << " and 10.\n";
showFees(CHILD, 10);
return 0;
}
//*********************************************************************
// Definition of function showFees. The memberRate parameter holds
// the monthly membership rate and the months parameter holds the
// number of months. The function displays the total charges.
|/********************************************************************
void showFees(double memberRate, int months)
{
cout << "The total charges are \$"
<< (memberRate * months) << endl;
}

```
```

Program Output
Testing an adult membership...
Calling the showFees function with arguments 40 and 10.
The total charges are \$400
Testing a senior citizen membership...
Calling the showFees function with arguments 30 and 10.
The total charges are \$300
Testing a child membership...
Calling the showFees function with arguments 20 and 10.
The total charges are \$200

```

As shown in Program 6-30, a driver can be used to thoroughly test a function. It can repeatedly call the function with different test values as arguments. When the function performs as desired, it can be placed into the actual program it will be part of.

Case Study: See High Adventure Travel Agency Part 1 Case Study on the Computer Science Portal at www.pearsonglobaleditions.com/gaddis.

\section*{Review Questions and Exercises}

\section*{Short Answer}
1. Why do local variables lose their values between calls to the function in which they are defined?
2. What is the difference between an argument and a parameter variable?
3. Where do you define parameter variables?
4. If you are writing a function that accepts an argument and you want to make sure the function cannot change the value of the argument, what do you do?
5. When a function accepts multiple arguments, does it matter in what order the arguments are passed?
6. How do you return a value from a function?
7. What is the advantage of breaking your application's code into several small procedures?
8. How would a static local variable be useful?
9. Give an example where passing an argument by reference would be useful.

\section*{Fill-in-the-Blank}
10. In the \(\qquad\) approach, a large problem is broken up into several smaller problems that can be easily solved.
11. The data type of the variable returned from a function is called \(\qquad\) .
12. Either a function's \(\qquad\) or its \(\qquad\) must precede all calls to the function.
13. The \(\qquad\) function is automatically invoked when execution of a program starts.
14. Special variables that hold copies of function arguments are called \(\qquad\) .
15. When only a copy of an argument is passed to a function, it is said to be passed by
\(\qquad\) _.
16. \(\mathrm{A}(\mathrm{n})\) \(\qquad\) eliminates the need to place a function definition before all calls to the function.
17. \(\mathrm{A}(\mathrm{n})\) \(\qquad\) variable is defined inside a function and is not accessible outside the function.
18. \(\qquad\) variables are defined outside all functions and are accessible to any function within their scope.
19. \(\qquad\) variables provide an easy way to share large amounts of data among all the functions in a program.
20. When the \(\qquad\) statement is encountered within a function, the control goes back to the statement that called the function.
21. If a function has a local variable with the same name as a global variable, only the
\(\qquad\) variable can be seen by the function.
22. \(\qquad\) local variables retain their value between function calls.
23. A \(\qquad\) is a named constant available to every function in a program.
24. \(\qquad\) arguments are passed to parameters automatically if no argument is provided in the function call.
25. When a function uses a mixture of parameters with and without default arguments, the parameters with default arguments must be defined \(\qquad\) -.
26. The value of a default argument must be a(n) \(\qquad\) .
27. When used as parameters, \(\qquad\) variables allow a function to access the parameter's original argument.
28. Reference variables are defined like regular variables, except there is a(n) \(\qquad\) in front of the name.
29. Only \(\qquad\) can be passed as a reference to a function.
30. Functions that have the same name but different parameter lists are called \(\qquad\)
31. A \(\qquad\) program is used to test whether a function is working properly.

\section*{Algorithm Workbench}
32. Examine the following function header, and then write two different examples to call the function:
double absolute ( double number );
33. The following statement calls a function named average. The average function returns the average of all the arguments passed to the function. Write the function. avg = average ( num1, num2, num3 );
34. A program contains the following function:
```

double velocity(double initial, double acceleration, double distance)
{
return initial * initial + 2 * acceleration * distance;
}

```

Write a statement that passes the values \(10.0,50.5\), and 100 to this function and assigns its return value to the variable final_velocity.
35. Write a function isValid that accepts an argument, grade. The function returns true if grade is within the range A through F; otherwise it returns false.
36. A program contains the following function:
```

void display(int arg1, double arg2, char arg3)
{
cout << "Here are the values: "
<< arg1 << " " << arg2 << " "
<< arg3 << endl;
}

```

Write a statement that calls the procedure and passes the following variables to it:
```

int age;
double income;
char initial;

```
37. Write a function named getNumber that uses a reference parameter variable to accept an integer argument. The function should prompt the user to enter a number in the range of 1 through 100 . The input should be validated and stored in the parameter variable.

\section*{True or False}
38. T F Functions should be given names that reflect their purpose.
39. T F Function headers are terminated with a semicolon.
40. T F A function may have more than one return statement.
41. T F If other functions are defined before main, the program still starts executing at function main.
42. T F When a function terminates, it always branches back to main, regardless of where it was called from.
43. T F Arguments are passed to the function parameters in the order they appear in the function call.
44. T F The scope of a parameter is limited to the function that uses it.
45. T F Changes to a function parameter always affect the original argument as well.
46. T F In a function prototype, the names of the parameter variables may be left out.
47. T F The lifetime of a local variable is throughout the execution of the program.
48. T F A local variable cannot have the same name as a global constant.
49. T F Static local variables are not destroyed when a function returns.
50. T F All static local variables are initialized to -1 by default.
51. T F Initialization of static local variables only happens once, regardless of how many times the function in which they are defined is called.
52. T F When a function with default arguments is called and an argument is left out, all arguments that come after it must be left out as well.
53. T F It is not possible for a function to have some parameters with default arguments and some without.
54. T F The exit function can only be called from main.
55. T F Stubs and drivers are tools that are used for testing and upgrading long programs that generally do not have any functions or sub-procedures in them.

\section*{Find the Errors}

Each of the following functions has errors. Locate as many errors as you can.
```

56. int product ( int num1; int num2; int num3 )
{
return num1 * num2 * num3;
}
```
57. double athird ( double number )
    \{
        int value \(=\) number / 3;
    return value;
    \}
58. void area(int length \(=30\), int width)
    \{
    return length * width;
    \}
59. void getValue(int value\&)
    \{
        cout << "Enter a value: ";
    cin >> value\&;
\}
60. (Overloaded functions)
```

int getValue()
{
int inputValue;
cout << "Enter an integer: ";
cin >> inputValue;
return inputValue;
}
double getValue()
{
double inputValue;
cout << "Enter a floating-point number: ";
cin >> inputValue;
return inputValue;
}

```

\section*{Programming Challenges}

\section*{1. Markup}

Write a program that asks the user to enter an item's wholesale cost and its markup percentage. It should then display the item's retail price. For example:
- If an item's wholesale cost is 5.00 and its markup percentage is 100 percent, then the item's retail price is 10.00 .
- If an item's wholesale cost is 5.00 and its markup percentage is 50 percent, then the item's retail price is 7.50 .
The program should have a function named calculateRetail that receives the wholesale cost and the markup percentage as arguments and returns the retail price of the item.
Input Validation: Do not accept negative values for either the wholesale cost of the item or the markup percentage.

\section*{2. Rectangle Area-Complete the Program}

If you have downloaded this book's source code, you will find a partially written program named AreaRectangle.cpp in the Chapter 06 folder. Your job is to complete the program. When it is complete, the program will ask the user to enter the width and length of a rectangle, then display the rectangle's area. The program calls the following functions, which have not been written:
- getLength-This function should ask the user to enter the rectangle's length then return that value as a double.
- getWidth-This function should ask the user to enter the rectangle's width then return that value as a double.
- getArea-This function should accept the rectangle's length and width as arguments and return the rectangle's area. The area is calculated by multiplying the length by the width.
- displayData-This function should accept the rectangle's length, width, and area as arguments and display them in an appropriate message on the screen.

\section*{3. Winning Division}

Write a program that determines which of a company's four divisions (Northeast, Southeast, Northwest, and Southwest) had the greatest sales for a quarter. It should include the following two functions, which are called by main:
- double getSales () is passed the name of a division. It asks the user for a division's quarterly sales figure, validates the input, then returns it. It should be called once for each division.
- void findHighest () is passed the four sales totals. It determines which is the largest and prints the name of the high-grossing division, along with its sales figure.
Input Validation: Do not accept dollar amounts less than \$0.00.

\section*{4. Safest Driving Area}

Write a program that determines which of five geographic regions within a major city (north, south, east, west, and central) had the fewest reported automobile accidents last year. It should have the following two functions, which are called by main:
- int getNumAccidents() is passed the name of a region. It asks the user for the number of automobile accidents reported in that region during the last year, validates the input, then returns it. It should be called once for each city region.
- void findLowest () is passed the five accident totals. It determines which is the smallest and prints the name of the region, along with its accident figure.
Input Validation: Do not accept an accident number that is less than 0.

\section*{5. Falling Distance}

When an object is falling because of gravity, the following formula can be used to determine the distance the object falls in a specific time period:
\(d=1 / 2 g t^{2}\)
The variables in the formula are as follows: \(d\) is the distance in meters, \(g\) is 9.8 , and \(t\) is the amount of time, in seconds, that the object has been falling.
Write a function named fall ingDistance that accepts an object's falling time (in seconds) as an argument. The function should return the distance, in meters, that the object has fallen during that time interval. Write a program that demonstrates the function by calling it in a loop that passes the values 1 through 10 as arguments and displays the return value.

\section*{6. Throwing Distance}

When throwing an object, the distance the object can reach is defined by the initial speed \(v\) and the angle \(\alpha\) with which the object is thrown. The actual formula for the distance \(D\) is as follows:
\(D=\frac{v^{2} \cdot \sin (2 \alpha)}{g}\)
The gravity constant \(g\) is defined as \(9.81 \mathrm{~m} / \mathrm{s}^{2}\).
Write a function named throwingDistance that accepts the initial speed and the angle (in degrees) as arguments, and returns the throwing distance. Demonstrate the function by calling it in a program that asks the user to enter a value for the speed and print out all angles from 0 to \(90^{\circ}\) with steps of \(5^{\circ}\).

\section*{7. Weight on Another Planet}

The weight of any object on a planet depends on both the radius and the mass of the planet itself, but the formula becomes very easy if you start with the object's weight on Earth. For example,
- for Venus, multiply the weight on Earth with 0.905
- for Mars, multiply with 0.3787
- for Jupiter, multiply with 2.53

Write a function named calculateWeight that accepts the name of the planet and an object's weight on Earth as arguments, and returns the weight on that planet. Demonstrate the function by calling it in a program that asks the user to enter values for the planet and the weight.

\section*{8. Coin Toss}

Write a function named coinToss that simulates the tossing of a coin. When you call the function, it should generate a random number in the range of 1 through 2 . If the random number is 1 , the function should display "heads." If the random number is 2 , the function should display "tails." Demonstrate the function in a program that asks the user how many times the coin should be tossed, then simulates the tossing of the coin that number of times.

\section*{9. Present Value}

Suppose you want to deposit a certain amount of money into a savings account and then leave it alone to draw interest for the next 10 years. At the end of 10 years, you would like to have \(\$ 10,000\) in the account. How much do you need to deposit today to
make that happen? You can use the following formula, which is known as the present value formula, to find out:
\(P=\frac{F}{(1+r)^{n}}\)
The terms in the formula are as follows:
- \(P\) is the present value, or the amount that you need to deposit today.
- \(F\) is the future value that you want in the account. (In this case, \(F\) is \(\$ 10,000\).)
- \(r\) is the annual interest rate.
- \(n\) is the number of years that you plan to let the money sit in the account.

Write a program that has a function named presentValue that performs this calculation. The function should accept the future value, annual interest rate, and number of years as arguments. It should return the present value, which is the amount that you need to deposit today. Demonstrate the function in a program that lets the user experiment with different values for the formula's terms.

\section*{10. Future Value}

Suppose you have a certain amount of money in a savings account that earns compound monthly interest, and you want to calculate the amount that you will have after a specific number of months. The formula, which is known as the future value formula, is
\(F=P \times(1+i)^{t}\)
The terms in the formula are as follows:
- \(F\) is the future value of the account after the specified time period.
- \(P\) is the present value of the account.
- \(i\) is the monthly interest rate.
- \(t\) is the number of months.

Write a program that prompts the user to enter the account's present value, monthly interest rate, and the number of months that the money will be left in the account. The program should pass these values to a function named futureValue that returns the future value of the account, after the specified number of months. The program should display the account's future value.

\section*{11. Calorie Calculator}

Write a function that calculates the number of "bad" calories in a recipe. In this assignment, calories are considered bad when coming from fat or sugar. It should use the following functions:
- void getWeight () should ask the user for a weight in pounds, store it in a reference parameter variable, and validate it. The function should be called for both the sugar and fat weights.
- double calculateCaloriesFat (double weight) accepts a weight as argument and returns the corresponding amount of calories by multiplying the weight with 4100 .
- double calculateCaloriesSugar(double weight) accepts a weight as argument and returns the corresponding amount of calories by multiplying the weight with 936.
- double calculateBadCalories() must use the aforementioned functions to let the user input weights for fat and sugar and return the total of bad calories.
Input Validation: Do not accept weights less than zero.

\section*{12. Average Speed}

A vehicle travels from city A to city B via city C. The average speed of the vehicle can be calculated by the following formula:
Average Speed \(=\frac{\text { Distance from city } A \text { to city } B+\text { Distance from city } B \text { to city } C}{\text { Time taken to go from } A \text { to } B+\text { Time taken to go from } B \text { to } C}\)
The time taken to cover any part of the journey can be calculated by the following formula:
Time taken from city \(X\) to city \(Y=\frac{\text { Distance between } X \text { and } Y}{\text { Speed between } X \text { and } Y}\)
Write a program that finds the average speed of the vehicle in its total journey from city A to city C using the above formulas. The program should ask the user to input the following:
- Distance between city A and city B
- Distance between city B and city C
- Speed of the vehicle while traveling from city A to city B
- Speed of the vehicle while traveling from city B to city C

The program should include a function named average_speed that accepts the four input values as parameters and returns the average speed. The program should then display the average speed.

\section*{13. Days Out}

Write a program that calculates the average number of days a company's employees are absent. The program should have the following functions:
- A function called by main that asks the user for the number of employees in the company. This value should be returned as an int. (The function accepts no arguments.)
- A function called by main that accepts one argument: the number of employees in the company. The function should ask the user to enter the number of days each employee missed during the past year. The total of these days should be returned as an int.
- A function called by main that takes two arguments: the number of employees in the company and the total number of days absent for all employees during the year. The function should return, as a double, the average number of days absent. (This function does not perform screen output and does not ask the user for input.)

Input Validation: Do not accept a number less than 1 for the number of employees. Do not accept a negative number for the days any employee missed.

\section*{14. Days Since the Year Began}

Write a function getDaysInMonth that accepts the number of the month as an argument: 1 for January, 2 for February, and so on. The function should return the number of days in that month in a non-leap year.
Demonstrate the function in a program that calculates the number of days since the beginning of the year. The user should enter the day ( \(1-31\) ), the month ( \(1-12\) ), and whether this is a leap year. Use the function getDaysInMonth to print out the number of days since the beginning of the year.
Input Validation: Months should be from 1 to 12, and days from 1 to 31 .

\section*{15. Overloaded Hospital}

Write a program that computes and displays the charges for a patient's hospital stay. First, the program should ask if the patient was admitted as an inpatient or an outpatient. If the patient was an inpatient, the following data should be entered:
- The number of days spent in the hospital
- The daily rate
- Hospital medication charges
- Charges for hospital services (lab tests, etc.)

The program should ask for the following data if the patient was an outpatient:
- Charges for hospital services (lab tests, etc.)
- Hospital medication charges

The program should use two overloaded functions to calculate the total charges. One of the functions should accept arguments for the inpatient data, while the other function accepts arguments for outpatient information. Both functions should return the total charges.
Input Validation: Do not accept negative numbers for any data.

\section*{16. Population}

In a population, the birth rate is the percentage increase of the population due to births, and the death rate is the percentage decrease of the population due to deaths. Write a program that displays the size of a population for any number of years. The program should ask for the following data:
- The starting size of a population
- The annual birth rate
- The annual death rate
- The number of years to display

Write a function that calculates the size of the population for a year. The formula is
```

N = P + BP - DP

```
where N is the new population size, P is the previous population size, B is the birth rate, and \(D\) is the death rate.
Input Validation: Do not accept numbers less than 2 for the starting size. Do not accept negative numbers for birth rate or death rate. Do not accept numbers less than 1 for the number of years.

\section*{17. Transient Population}

Modify Programming Challenge 16 to also consider the effect on population caused by people moving into or out of a geographic area. Given as input a starting population size, the annual birth rate, the annual death rate, the number of individuals who typically move into the area each year, and the number of individuals who typically leave the area each year, the program should project what the population will be numYears from now. You can either prompt the user to input a value for numYears, or you can set it within the program.
Input Validation: Do not accept numbers less than 2 for the starting size. Do not accept negative numbers for birth rate, death rate, arrivals, or departures.

\section*{18. Estimate Number of Containers}

Bin packing is a typical algorithmic problem in computer science where one wants an optimal packing of boxes into as few containers as possible. In this assignment, we implement a very simple algorithm: we stack the boxes in a container in the same order as they are presented and start a new container as soon as the accumulated volume would exceed \(100 \mathrm{ft}^{3}\). This means that we do not take into account the fact that boxes may not perfectly stack.
Write a function that takes the width, height, and depth of a box as arguments (in feet) and returns the volume of the box ( \(\mathrm{w}^{*} \mathrm{~h}^{*} \mathrm{~d}\) ).
Use this function in a program that lets the user enter an unlimited number of boxes and calculates the number of containers needed. The user ends the input by entering 0 .

Input Validation: The width, height, and depth should always be greater than 0.
19. Using Files-Hospital Report

Modify Programming Challenge 15 (Overloaded Hospital) to write the report it creates to a file.
20. Heating Energy

The heat capacity of a material is the amount of energy in joules it takes to heat up the material by \(1^{\circ} \mathrm{C}\) or 1 K . For example, the heat capacity of water is approximately \(4.2 \mathrm{~J} /(\mathrm{g} \mathrm{K})\). This means that you need 4.2 joules (J) to heat up \(1 \mathrm{gram}(\mathrm{g})\) of water by 1 Kelvin (K).
Given that 1 lb equals approximately 453.59 grams and \(1^{\circ} \mathrm{F}\) equals \(5 / 9^{\circ} \mathrm{C}\), write a function that takes as arguments the amount of water in lb and the desired temperature increase in \({ }^{\circ} \mathrm{F}\). The function should return the amount of joules needed. Demonstrate the function in a program that asks the user to enter the necessary data.

Input Validation: Do not accept a negative value for the amount of water.

\section*{21. Heating Time}

A typical electrical water heater consumes 1000 W : it generates \(1000 \mathrm{~J} / \mathrm{s}\) when switched on. Use this knowledge and the function of Programming Challenge 20 to write a function that takes as arguments the amount of water and the current temperature of the water. The function should return the time in seconds to heat the water to cooking temperature \(\left(212^{\circ} \mathrm{F}\right)\).

\section*{22. isPrime Function}

A prime number is a number that is only evenly divisible by itself and 1 . For example, the number 5 is prime because it can only be evenly divided by 1 and 5 . The number 6 , however, is not prime because it can be divided evenly by \(1,2,3\), and 6 .
Write a function name isPrime, which takes an integer as an argument and returns true if the argument is a prime number, or fal se otherwise. Demonstrate the function in a complete program.

TIP: Recall that the \% operator divides one number by another, and returns the remainder of the division. In an expression such as num1 \% num2, the \% operator will return 0 if num1 is evenly divisible by num2.

\section*{23. Prime Number List}

Use the isPrime function that you wrote in Programming Challenge 22 (isPrime function) in a program that stores a list of all the prime numbers from 1 through 100 in a file.

\section*{24. Rock, Paper, Scissors Game}

Write a program that lets the user play the game of Rock, Paper, Scissors against the computer. The program should work as follows:
1. When the program begins, a random number in the range of 1 through 3 is generated. If the number is 1 , then the computer has chosen rock. If the number is 2 , then the computer has chosen paper. If the number is 3 , then the computer has chosen scissors. (Don't display the computer's choice yet.)
2. The user enters his or her choice of "rock", "paper", or "scissors" at the keyboard. (You can use a menu if you prefer.)
3. The computer's choice is displayed.
4. A winner is selected according to the following rules:
- If one player chooses rock and the other player chooses scissors, then rock wins. (The rock smashes the scissors.)
- If one player chooses scissors and the other player chooses paper, then scissors wins. (Scissors cuts paper.)
- If one player chooses paper and the other player chooses rock, then paper wins. (Paper wraps rock.)
- If both players make the same choice, the game must be played again to determine the winner.

Be sure to divide the program into functions that perform each major task.

\section*{Group Project}

\section*{25. Travel Expenses}

This program should be designed and written by a team of students. Here are some suggestions:
- One student should design function main, which will call the other functions in the program. The remainder of the functions will be designed by other members of the team.
- The requirements of the program should be analyzed so each student is given about the same workload.
- The parameters and return types of each function should be decided in advance.
- Stubs and drivers should be used to test and debug the program.
- The program can be implemented as a multi-file program, or all the functions can be cut and pasted into the main file.

Here is the assignment: Write a program that calculates and displays the total travel expenses of a businessperson on a trip. The program should have functions that ask for and return the following:
- The total number of days spent on the trip
- The time of departure on the first day of the trip, and the time of arrival back home on the last day of the trip
- The amount of any round-trip airfare
- The amount of any car rentals
- Miles driven, if a private vehicle was used. Calculate the vehicle expense as \(\$ 0.27\) per mile driven
- Parking fees (The company allows up to \(\$ 6\) per day. Anything in excess of this must be paid by the employee.)
- Taxi fees, if a taxi was used anytime during the trip (The company allows up to \(\$ 10\) per day, for each day a taxi was used. Anything in excess of this must be paid by the employee.)
- Conference or seminar registration fees
- Hotel expenses (The company allows up to \(\$ 90\) per night for lodging. Anything in excess of this must be paid by the employee.)
- The amount of each meal eaten. On the first day of the trip, breakfast is allowed as an expense if the time of departure is before \(7 \mathrm{a} . \mathrm{m}\). Lunch is allowed if the time of departure is before 12 noon. Dinner is allowed on the first day if the time of departure is before \(6 \mathrm{p} . \mathrm{m}\). On the last day of the trip, breakfast is allowed if the time of arrival is after \(8 \mathrm{a} . \mathrm{m}\). Lunch is allowed if the time of arrival is after \(1 \mathrm{p} . \mathrm{m}\). Dinner is allowed on the last day if the time of arrival is after 7 p.m. The program should only ask for the amounts of allowable meals. (The company allows up to \(\$ 9\) for breakfast, \(\$ 12\) for lunch, and \(\$ 16\) for dinner. Anything in excess of this must be paid by the employee.)
The program should calculate and display the total expenses incurred by the businessperson, the total allowable expenses for the trip, the excess that must be reimbursed by the businessperson, if any, and the amount saved by the businessperson if the expenses were under the total allowed.
Input Validation: Do not accept negative numbers for any dollar amount or for miles driven in a private vehicle. Do not accept numbers less than 1 for the number of days. Only accept valid times for the time of departure and the time of arrival.

7.9 Arrays with Three or More Dimensions
7.10 Focus on Problem Solving and Program Design: A Case Study
7.11 Introduction to the STL vector

\subsection*{7.1 Arrays Hold Multiple Values}

CONCEPT: An array allows you to store and work with multiple values of the same data type.

The variables you have worked with so far are designed to hold only one value at a time. Each of the variable definitions in Figure 7-1 causes only enough memory to be reserved to hold one value of the specified data type.

Figure 7-1 Variables can hold one value at a time
int count; Enough memory for 1 int 12314
float price; Enough memory for 1 float
56.981
char 1etter; Enough memory for 1 char
A

An array works like a variable that can store a group of values, all of the same type. The values are stored together in consecutive memory locations. Here is a definition of an array of integers:
```

int days[6];

```

The name of this array is days. The number inside the brackets is the array's size declarator It indicates the number of elements, or values, the array can hold. The days array can store six elements, each one an integer. This is depicted in Figure 7-2.

Figure 7-2 An array with six elements days array: Enough memory for six int values

An array's size declarator must be a constant integer expression with a value greater than zero. It can be either a literal, as in the previous example, or a named constant, as shown in the following:
```

const int NUM_DAYS = 6;
int days[NUM_DAYS];

```

Arrays of any data type can be defined. The following are all valid array definitions:
```

float temperatures[100]; // Array of 100 floats
string names[10]; // Array of 10 string objects
long units[50]; // Array of 50 long integers
double sizes[1200]; // Array of 1200 doubles

```

\section*{Memory Requirements of Arrays}

The amount of memory used by an array depends on the array's data type and the number of elements. The hours array, defined here, is an array of six shorts.
short hours[6];
On a typical system, a short uses 2 bytes of memory, so the hours array would occupy 12 bytes. This is shown in Figure 7-3.

Figure 7-3 Array memory usage
hours array: Each element uses 2 bytes

The size of an array can be calculated by multiplying the size of an individual element by the number of elements in the array. Table 7-1 shows the typical sizes of various arrays.

Table 7-1 Arrays and Their sizes
\begin{tabular}{llll}
\hline Array Definition & Number of Elements & Size of Each Element & Size of the Array \\
\hline char letters[25]; & 25 & 1 byte & 25 bytes \\
short rings[100] ; & 100 & 2 bytes & 200 bytes \\
int miles[84] ; & 84 & 4 bytes & 336 bytes \\
float temp[12] ; & 12 & 4 bytes & 48 bytes \\
double distance[1000] \(;\) & 1000 & 8 bytes & 8000 bytes \\
\hline
\end{tabular}

\subsection*{7.2 Accessing Array Elements}

CONCEPT: The individual elements of an array are assigned unique subscripts. These subscripts are used to access the elements.

Even though an entire array has only one name, the elements may be accessed and used as individual variables. This is possible because each element is assigned a number known as a subscript. A subscript is used as an index to pinpoint a specific element within an array. The first element is assigned the subscript 0 , the second element is assigned 1 , and so forth. The six elements in the array hours would have the subscripts 0 through 5 . This is shown in Figure 7-4.

Figure 7-4 Subscripts
Subscripts

NOTE: Subscript numbering in C++ always starts at zero. The subscript of the last element in an array is one less than the total number of elements in the array. This means that in the array shown in Figure 7-4, the element hours [6] does not exist. hours [5] is the last element in the array.

Each element in the hours array, when accessed by its subscript, can be used as a short variable. Here is an example of a statement that stores the number 20 in the first element of the array:
```

hours[0] = 20;

```

NOTE: The expression hours[0] is pronounced "hours sub zero." You would read this assignment statement as "hours sub zero is assigned twenty."

Figure 7-5 shows the contents of the hours array after the statement assigns 20 to hours [0].
Figure 7-5 Contents of the hours array

NOTE: Because values have not been assigned to the other elements of the array, question marks will be used to indicate that the contents of those elements are unknown. If an array is defined globally, all of its elements are initialized to zero by default. Local arrays, however, have no default initialization value.

The following statement stores the integer 30 in hours [3]:
```

hours[3] = 30;

```

Figure 7-6 shows the contents of the array after the previous statement executes.

Figure 7-6 Contents of the hours array

NOTE: Understand the difference between the array size declarator and a subscript. The number inside the brackets of an array definition is the size declarator. The number inside the brackets of an assignment statement or any statement that works with the contents of an array is a subscript.

\section*{Inputting and Outputting Array Contents}

Array elements may be used with the cin and cout objects like any other variable. Program \(7-1\) shows the array hours being used to store and display values entered by the user.

\section*{Program 7-1}
```

// This program asks for the number of hours worked
// by six employees. It stores the values in an array.
\#include <iostream>
using namespace std;
int main()
{
const int NUM_EMPLOYEES = 6;
int hours[NUM_EMPLOYEES];
// Get the hours worked by each employee.
cout << "Enter the hours worked by "
<< NUM_EMPLOYEES << " employees: ";
cin >> hours[0];
cin >> hours[1];
cin >> hours[2];
cin >> hours[3];
cin >> hours[4];
cin >> hours[5];
// Display the values in the array.
cout << "The hours you entered are:";
cout << " " << hours[0];
cout << " " << hours[1];
cout << " " << hours[2];
cout << " " << hours[3];
cout << " " << hours[4];
cout << " " << hours[5] << endl;
return 0;
}

```

\section*{Program Output with Example Input Shown in Bold}

Enter the hours worked by 6 employees: 201240303015 Enter
The hours you entered are: 201240303015

Figure \(7-7\) shows the contents of the array hours with the values entered by the user in the example output above.

Figure 7-7 Contents of the hours array

Even though the size declarator of an array definition must be a constant or a literal, subscript numbers can be stored in variables. This makes it possible to use a loop to "step through" an entire array, performing the same operation on each element. For example, look at the following code:
```

const int ARRAY_SIZE = 5;
int numbers[ARRAY_SIZE];
for (int count = 0; count < ARRAY_SIZE; count++)
numbers[count] = 99;

```

This code first defines a constant int named ARRAY_SIZE and initializes it with the value 5. Then, it defines an int array named numbers, using ARRAY_SIZE as the size declarator. As a result, the numbers array will have five elements. The for loop uses a counter variable named count. This loop will iterate five times, and during the loop iterations the count variable will take on the values 0 through 4 .

Notice the statement inside the loop uses the count variable as a subscript. It assigns 99 to numbers [count ]. During the first iteration, 99 is assigned to numbers [ 0 ]. During the next iteration, 99 is assigned to numbers [1]. This continues until 99 has been assigned to all of the array's elements. Figure 7-8 illustrates that the loop's initialization, test, and update expressions have been written so that the loop starts and ends the counter variable with valid subscript values ( 0 through 4 ). This ensures that only valid subscripts are used in the body of the loop.

Figure 7-8 Initialization, test, and update expressions

Program 7-1 could be simplified by using two for loops: one for inputting the values into the array, and another for displaying the contents of the array. This is shown in Program 7-2.

\section*{Program 7-2}
```

// This program asks for the number of hours worked
// by six employees. It stores the values in an array.
\#include <iostream>
using namespace std;

```
```

int main()
{
const int NUM_EMPLOYEES = 6; // Number of employees
int hours[NUM_EMPLOYEES]; // Each employee's hours
int count; // Loop counter
// Input the hours worked.
for (count = 0; count < NUM_EMPLOYEES; count++)
{
cout << "Enter the hours worked by employee "
<< (count + 1) << ": ";
cin >> hours[count];
}
// Display the contents of the array.
cout << "The hours you entered are:";
for (count = 0; count < NUM_EMPLOYEES; count++)
cout << " " << hours[count];
cout << endl;
return 0;
}

```

\section*{Program Output with Example Input Shown in Bold}

Enter the hours worked by employee 1: 20 Enter
Enter the hours worked by employee 2: 12 Enter
Enter the hours worked by employee 3: 40 Enter
Enter the hours worked by employee 4: 30 Enter
Enter the hours worked by employee 5: \(\mathbf{3 0}\) Enter
Enter the hours worked by employee 6: 15 Enter
The hours you entered are: 201240303015

The first for loop, in lines 13 through 18, prompts the user for each employee's hours. Take a closer look at lines 15 through 17:
```

cout << "Enter the hours worked by employee "
<< (count + 1) << ": ";
cin >> hours[count];

```

Notice the cout statement uses the expression count +1 to display the employee number, but the cin statement uses count as the array subscript. This is because the hours for employee number 1 are stored in hours[ 0 ], the hours for employee number 2 are stored in hours [1], and so forth.

The loop in lines 22 and 23 also uses the count variable to step through the array, displaying each element.

NOTE: You can use any integer expression as an array subscript. For example, the first loop in Program 7-2 could have been written like this:
```

for (count = 1; count <= NUM_EMPLOYEES; count++)
{
cout << "Enter the hours worked by employee "
<< count << ": ";
cin >> hours[count - 1];
}

```

In this code, the cin statement uses the expression count - 1 as a subscript.

Inputting data into an array must normally be done one element at a time. For example, the following cin statement will not input data into the hours array:
```

cin >> hours; // Wrong! This will NOT work.

```

Instead, you must use multiple cin statements to read data into each array element, or use a loop to step through the array, reading data into its elements. Also, outputting an array's contents must normally be done one element at a time. For example, the following cout statement will not display the contents of the hours array:
```

cout << hours; // Wrong! This will NOT work.

```

Instead, you must output each element of the array separately.

\section*{Array Initialization}

Like regular variables, \(\mathrm{C}++\) allows you to initialize an array's elements when you create the array. Here is an example:
```

const int MONTHS = 12;
int days[MONTHS] = {31, 28, 31, 30, 31, 30, 31, 31, 30, 31, 30, 31};

```

The series of values inside the braces and separated with commas is called an initialization list. These values are stored in the array elements in the order they appear in the list. (The first value, 31, is stored in days [0], the second value, 28, is stored in days [1], and so forth.) Figure \(7-9\) shows the contents of the array after the initialization.

Figure 7-9 The array after initialization
Subscripts
\begin{tabular}{|c|c|c|c|c|c|c|c|c|c|c|c|}
\hline 0 & 1 & 2 & 3 & 4 & 5 & 6 & 7 & 8 & 9 & 10 & 11 \\
\hline 31 & 28 & 31 & 30 & 31 & 30 & 31 & 31 & 30 & 31 & 30 & 31 \\
\hline
\end{tabular}

Program 7-3 demonstrates how an array may be initialized.

\section*{Program 7-3}
```

// This program displays the number of days in each month.
\#include <iostream>
using namespace std;
int main()
{
const int MONTHS = 12;
int days[MONTHS] = { 31, 28, 31, 30,
31, 30, 31, 31,
30, 31, 30, 31 };
for (int count = 0; count < MONTHS; count++)
{
cout << "Month " << (count + 1) << " has ";
cout << days[count] << " days.\n";
}
return 0;
}

```

\section*{Program Output}
```

Month 1 has 31 days.
Month 2 has 28 days.
Month 3 has 31 days.
Month 4 has 30 days.
Month 5 has 31 days.
Month 6 has 30 days.
Month }7\mathrm{ has }31\mathrm{ days.
Month }8\mathrm{ has }31\mathrm{ days.
Month 9 has 30 days.
Month }10\mathrm{ has }31\mathrm{ days.
Month }11\mathrm{ has }30\mathrm{ days.
Month 12 has 31 days.

```

NOTE: C++ allows you to spread the initialization list across multiple lines. Both of the following array definitions are equivalent:
```

double coins[5] = {0.05, 0.1, 0.25, 0.5, 1.0};
double coins[5] = {0.05,
0.1,
0.25,
0.5,
1.0};

```

Program 7-4 shows an example with a string array that is initialized with strings.

\section*{Program 7-4}
```

// This program initializes a string array.
\#include<iostream>
\#include<string>
using namespace std;
int main()
{
const int SIZE = 9;
string planets[SIZE] = { "Mercury", "Venus", "Earth", "Mars",
"Jupiter", "Saturn", "Uranus",
"Neptune", "Pluto (a dwarf planet)" };
cout << "Here are the planets:\n";
for (int count = 0; count < SIZE; count++)
cout << planets[count] << endl;
return 0;
}

```

\section*{Program Output}

Here are the planets:
Mercury
Venus
Earth
Mars
Jupiter
Saturn
Uranus
Neptune
Pluto (a dwarf planet)

Program 7-5 shows a character array being initialized with the first ten letters of the alphabet. The array is then used to display those characters' ASCII codes.

\section*{Program 7-5}
```

// This program uses an array of ten characters to store the
// first ten letters of the alphabet. The ASCII codes of the
// characters are displayed.
\#include <iostream>
using namespace std;
int main()
{
const int NUM_LETTERS = 10;
char letters[NUM_LETTERS] = {'A', 'B', 'C', 'D', 'E',
'F', 'G', 'H', 'I', 'J'};

```
```

    cout << "Character" << "\t" << "ASCII Code\n";
    cout << "---------" << "\t" << "----------\n";
    for (int count = 0; count < NUM_LETTERS; count++)
    {
    cout << letters[count] << "\t\t";
    cout << static_cast<int>(letters[count]) << endl;
    }
    return 0;
    }

```
Program Output
Character ASCII Code
----------------
A 65
B 66
C 67
D 68
E 69
F 70
G 71
H 72
I 73
J 74

NOTE: An array's initialization list cannot have more values than the array has elements.

\section*{Partial Array Initialization}

When an array is being initialized, C++ does not require a value for every element. It's possible to only initialize part of an array, such as:
```

int numbers[7] = {1, 2, 4, 8};

```

This definition initializes only the first four elements of a 7-element array, as illustrated in Figure 7-10.

Figure 7-10 Partial array initialization

It's important to note that if an array is partially initialized, the uninitialized elements will be set to zero. The uninitialized elements of a string array will contain empty strings. This is true even if the array is defined locally. (If a local array is completely uninitialized, its elements will contain "garbage," like all other local variables.) Program 7-6 shows the contents of the numbers array after it is partially initialized.

\section*{Program 7-6}
```

// This program has a partially initialized array.
\#include <iostream>
using namespace std;
int main()
{
const int SIZE = 7;
int numbers[SIZE] = {1, 2, 4, 8}; // Initialize first 4 elements
cout << "Here are the contents of the array:\n";
for (int index = 0; index < SIZE; index++)
cout << numbers[index] << " ";
cout << endl;
return 0;
}

```

\section*{Program Output}

Here are the contents of the array:
1248000

If you leave an element uninitialized, you must leave all the elements that follow it uninitialized as well. C++ does not provide a way to skip elements in the initialization list. For example, the following is not legal:
```

int numbers[6] = {2, 4, , 8, , 12}; // NOT Lega1!

```

\section*{Implicit Array Sizing}

It's possible to define an array without specifying its size, as long as you provide an initialization list. C++ automatically makes the array large enough to hold all the initialization values. For example, the following definition creates an array with five elements:
```

double ratings[] = {1.0, 1.5, 2.0, 2.5, 3.0};

```

Because the size declarator is omitted, \(\mathrm{C}++\) counts the number of items in the initialization list and gives the array that many elements.

NOTE: You must provide an initialization list if you leave out an array's size declarator. Otherwise, the compiler doesn't know how large to make the array.

\section*{Reading Data from a File into an Array}

Reading the contents of a file into an array is straightforward: Open the file and use a loop to read each item from the file, storing each item in an array element. The loop should iterate until either the array is filled or the end of the file is reached. Program 7-7 demonstrates by opening a file that has 10 numbers stored in it then reading the file's contents into an array.

\section*{Program 7-7}
```

// This program reads data from a file into an array.
\#include <iostream>
\#include <fstream>
using namespace std;
int main()
{
const int ARRAY_SIZE = 10; // Array size
int numbers[ARRAY_SIZE]; // Array with 10 elements
int count = 0; // Loop counter variable
ifstream inputFile; // Input file stream object
// Open the file.
inputFile.open("TenNumbers.txt");
// Read the numbers from the file into the array.
while (count < ARRAY_SIZE \&\& inputFile >> numbers[count])
count++;
// Close the file.
inputFile.close();
// Display the numbers read:
cout << "The numbers are: ";
for (count = 0; count < ARRAY_SIZE; count++)
cout << numbers[count] << " ";
cout << endl;
return 0;
}

```

\section*{Program Output}

The while loop in lines 17 and 18 reads items from the file and assigns them to elements of the numbers array. Notice the loop tests two Boolean expressions, connected by the \&\& operator:
- The first expression is count < ARRAY_SIZE. The purpose of this expression is to prevent the loop from writing beyond the end of the array. If the expression is true, the second Boolean expression is tested. If this expression is false, however, the loop stops.
- The second expression is inputFile >> numbers[count]. This expression reads a value from the file and stores it in the numbers [count] array element. If a value is successfully read from the file, the expression is true and the loop continues. If no value can be read from the file, however, the expression is false and the loop stops.
Each time the loop iterates, it increments count in line 18.

\section*{Writing the Contents of an Array to a File}

Writing the contents of an array to a file is also a straightforward matter. Use a loop to step through each element of the array, writing its contents to a file. Program 7-8 demonstrates this.

\section*{Program 7-8}
```

// This program writes the contents of an array to a file.
\#include <iostream>
\#include <fstream>
using namespace std;
int main()
{
const int ARRAY_SIZE = 10; // Array size
int numbers[ARRAY_SIZE]; // Array with 10 elements
int count; // Loop counter variable
ofstream outputFile; // Output file stream object
// Store values in the array.
for (count = 0; count < ARRAY_SIZE; count++)
numbers[count] = count;
// Open a file for output.
outputFile.open("SavedNumbers.txt");
// Write the array contents to the file.
for (count = 0; count < ARRAY_SIZE; count++)
outputFile << numbers[count] << endl;
// Close the file.
outputFile.close();
// That's it!
cout << "The numbers were saved to the file.\n ";
return 0;
}

```

\section*{Program Output}

The numbers were saved to the file.

Contents of the File SavedNumbers.txt

\subsection*{7.3 No Bounds Checking in C++}

\section*{CONCEPT: C++ does not prevent you from overwriting an array's bounds.}

C++ is a popular language for software developers who have to write fast, efficient code. To increase runtime efficiency, \(\mathrm{C}++\) does not provide many of the common safeguards to prevent unsafe memory access found in other languages. For example, C++ does not perform array bounds checking. This means you can write programs with subscripts that go beyond the boundaries of a particular array. Program 7-9 demonstrates this capability.

WARNING! Program 7-9 will attempt to write to an area of memory outside the array. This is an invalid operation and will most likely cause the program to crash.

\section*{Program 7-9}
```

// This program unsafely accesses an area of memory by writing
// values beyond an array's boundary.
// WARNING: If you compile and run this program, it could crash.
\#include <iostream>
using namespace std;
int main()
{
const int SIZE = 3; // Constant for the array size
int values[SIZE]; // An array of 3 integers
int count; // Loop counter variable
// Attempt to store five numbers in the 3-element array.
cout << "I will store 5 numbers in a 3-element array!\n";
for (count = 0; count < 5; count++)
values[count] = 100;
// If the program is still running, display the numbers.
cout << "If you see this message, it means the program\n";
cout << "has not crashed! Here are the numbers:\n";
for (count = 0; count < 5; count++)
cout << values[count] << endl;
return 0;
}

```

The values array has three integer elements, with the subscripts 0 , 1 , and 2 . The loop, however, stores the number 100 in elements \(0,1,2,3\), and 4 . The elements with subscripts 3 and 4 do not exist, but C++ allows the program to write beyond the boundary of the array, as if those elements were there. Figure 7-11 depicts the way the array is set up in memory when the program first starts to execute, and what happens when the loop writes data beyond the boundary of the array.

Figure 7-11 Writing data beyond the bounds of an array

Although C++ programs are fast and efficient, the absence of safeguards such as array bounds checking usually proves to be a bad thing. It's easy for C++ programmers to make careless mistakes that allow programs to access areas of memory that are supposed to be off-limits. You must always make sure that any time you assign values to array elements, the values are written within the array's boundaries.

\section*{Watch for Off-by-One Errors}

In working with arrays, a common type of mistake is the off-by-one error. This is an easy mistake to make because array subscripts start at 0 rather than 1 . For example, look at the following code:
```

// This code has an off-by-one error.
const int SIZE = 100;
int numbers[SIZE];
for (int count = 1; count <= SIZE; count++)
numbers[count] = 0;

```

The intent of this code is to create an array of integers with 100 elements, and store the value 0 in each element. However, this code has an off-by-one error. The loop uses its counter variable, count, as a subscript with the numbers array. During the loop's execution, the variable count takes on the values 1 through 100 , when it should take on the values 0 through 99 . As a result, the first element, which is at subscript 0 , is skipped. In addition, the loop attempts to use 100 as a subscript during the last iteration. Because 100 is an invalid subscript, the program will write data beyond the array's boundaries.

\section*{Checkpoint}
7.1 Define the following arrays:
A) empNums, a 100 -element array of ints
B) payRates, a 25 -element array of floats
C) miles, a 14 -element array of 1 ongs
D) cityName, a 26 -element array of string objects
E) 1 ightYears, a 1,000 -element array of doubles
7.2 What's wrong with the following array definitions?
```

int readings[-1];
float measurements[4.5];
int size;
string names[size];

```
7.3 What would the valid subscript values be in a 4-element array of doubles?
7.4 What is the difference between an array's size declarator and a subscript?
7.5 What is "array bounds checking"? Does C++ perform it?
7.6 What is the output of the following code?
```

int values[5], count;
for (count = 0; count < 5; count++)
values[count] = count + 1;
for (count = 0; count < 5; count++)
cout << values[count] << endl;

```
7.7 The following program skeleton contains a 20-element array of ints called fish. When completed, the program should ask how many fish were caught by fishermen 1 through 20, and store this data in the array. Complete the program.
\#include <iostream>
using namespace std;
int main()
\{
    const int NUM_FISH = 20;
    int fish[NUM_FISH];
    // You must finish this program. It should ask how
    // many fish were caught by fishermen 1-20, and
    // store this data in the array fish.
    return 0;
\}
7.8 Define the following arrays:
A) ages, a 10 -element array of ints initialized with the values \(5,7,9,14,15\), \(17,18,19,21\), and 23 .
B) temps, a 7 -element array of floats initialized with the values \(14.7,16.3\), 18.43, 21.09, 17.9, 18.76, and 26.7.
C) alph , an 8 -element array of chars initialized with the values ' \(J\) ', ' \(B\) ', ' L , ' \(A\) ', '*', '\$', 'H', and 'M'.
7.9 Is each of the following a valid or invalid array definition? (If a definition is invalid, explain why.)
A) int numbers[10] \(=\{0,0,1,0,0,1,0,0,1,1\}\);
B) int matrix[5] \(=\{1,2,3,4,5,6,7\}\);
C) double radii[10] \(=\{3.2,4.7\}\);
D) int table[7] \(=\{2\), , 27, , 45, 39\};
E) char codes[] = \{'A', 'X', '1', '2', 's'\};
F) int blanks[];

\subsection*{7.4 The Range-Based for Loop}

CONCEPT: The range-based for loop is a loop that iterates once for each element in an array. Each time the loop iterates, it copies an element from the array to a variable. The range-based for loop was introduced in C++ 11 .

C++ 11 provides a specialized version of the for loop that, in many circumstances, simplifies array processing. It is known as the range-based for loop. When you use the rangebased for loop with an array, the loop automatically iterates once for each element in the array. For example, if you use the range-based for loop with an 8 -element array, the loop will iterate 8 times. Because the range-based for loop automatically knows the number of elements in an array, you do not have to use a counter variable to control its iterations, as with a regular for loop. Additionally, you do not have to worry about stepping outside the bounds of an array when you use the range-based for loop.

The range-based for loop is designed to work with a built-in variable known as the range variable. Each time the range-based for loop iterates, it copies an array element to the range variable. For example, the first time the loop iterates, the range variable will contain the value of element 0 , the second time the loop iterates, the range variable will contain the value of element 1 , and so forth.
Here is the general format of the range-based for loop:
```

for (dataType rangeVariab7e : array)
statement;

```

Let's look at the syntax more closely as follows:
- dataType is the data type of the range variable. It must be the same as the data type of the array elements, or a type to which the elements can automatically be converted.
- rangeVariable is the name of the range variable. This variable will receive the value of a different array element during each loop iteration. During the first loop iteration, it receives the value of the first element; during the second iteration, it receives the value of the second element, and so forth.
- array is the name of an array on which you wish the loop to operate. The loop will iterate once for every element in the array.
- statement is a statement that executes during a loop iteration. If you need to execute more than one statement in the loop, enclose the statements in a set of braces.

For example, assume that you have the following array definition:
```

int numbers[] = { 3, 6, 9 };

```

You can use the following range-based for loop to display the contents of the numbers array:
```

for (int val : numbers)
cout << val << endl;

```

Because the numbers array has three elements, this loop will iterate three times. The first time it iterates, the val variable will receive the value in numbers [0]. During the second iteration, val will receive the value in numbers[1]. During the third iteration, val will receive the value in numbers [2]. The code's output will be as follows:

3
6
9
Here is an example of a range-based for loop that executes more than one statement in the body of the loop:
```

int[] numbers = { 3, 6, 9 };
for (int val : numbers)
{
cout << "The next value is ";
cout << val << endl;
}

```

This code will produce the following output:
```

The next value is 3
The next value is 6
The next value is 9

```

If you wish, you can use the auto key word to specify the range variable's data type. Here is an example:
```

int[] numbers = { 3, 6, 9 };
for (auto val : numbers)
cout << val << endl;

```

Program 7-10 demonstrates the range-based for loop by displaying the elements of an int array.

\section*{Program 7-10}
// This program demonstrates the range-based for loop.
\#include <iostream>
using namespace std;
int main()
\{
// Define an array of integers.
int numbers[] \(=\{10,20,30,40,50\}\);
// Display the values in the array. for (int val : numbers) cout << val << endl;
return 0;
\}
```

Program 7-10
(continued)
Program Output
10
20
30
4 0
50

```

Program 7-11 shows another example of the range-based for loop. This program displays the elements of a string array.

\section*{Program 7-11}
```

// This program demonstrates the range-based for loop.
\#include <iostream>
\#include <string>
using namespace std;
int main()
{
string planets[] = { "Mercury", "Venus", "Earth", "Mars",
"Jupiter", "Saturn", "Uranus",
"Neptune", "Pluto (a dwarf planet)" };
cout << "Here are the planets:\n";
// Display the values in the array.
for (string val : planets)
cout << val << endl;
return 0;
}

```

\section*{Program Output}

Here are the planets:
Mercury
Venus
Earth
Mars
Jupiter
Saturn
Uranus
Neptune
Pluto (a dwarf planet)

\section*{Modifying an Array with a Range-Based for Loop}

As the range-based for loop executes, its range variable contains only a copy of an array element. As a consequence, you cannot use a range-based for loop to modify the contents
of an array unless you declare the range variable as a reference. Recall from Chapter 6 that a reference variable is an alias for another value. Any changes made to the reference variable are actually made to the value for which it is an alias.

To declare the range variable as a reference variable, simply write an ampersand (\&) in front of its name in the loop header. Program 7-12 shows an example.

\section*{Program 7-12}
```

// This program uses a range-based for loop to
// modify the contents of an array.
\#include <iostream>
using namespace std;
int main()
{
const int SIZE = 5;
int numbers[5];
// Get values for the array.
for (int \&val : numbers)
{
cout << "Enter an integer value: ";
cin >> val;
}
// Display the values in the array.
cout << "Here are the values you entered:\n";
for (int val : numbers)
cout << val << endl;
return 0;
}

```

\section*{Program Output with Example Input Shown in Bold}
```

Enter an integer value: 1 Enter
Enter an integer value: 2 Enter
Enter an integer value: 3 Enter
Enter an integer value: 4 Enter
Enter an integer value: 5 Enter
Here are the values you entered:
1
2
3
4
5

```

Notice in line 12 the range variable, val, has an ampersand (\&) written in front of its name. This declares val as a reference variable. As the loop executes, the val variable will not merely contain a copy of an array element, but it will be an alias for the element. Any changes made to the val variable will actually be made to the array element it references.

Also notice in line 20, we did not declare val as a reference variable (there is no ampersand written in front of the variable's name). Because the loop is simply displaying the array elements, and does not need to change the array's contents, there is no need to make val a reference variable.

\section*{The Range-Based for Loop versus the Regular for Loop}

The range-based for loop can be used in any situation where you need to step through the elements of an array, and you do not need to use the element subscripts. It will not work, however, in situations where you need the element subscript for some purpose. In those situations, you need to use the regular for loop.

NOTE: You can use the auto key word with a reference range variable. For example, the code in lines 12 through 16 in Program 7-12 could have been written like this:
```

for (auto \&val : numbers)
{
cout << "Enter an integer value: ";
cin >> val;
}

```

\subsection*{7.5 Processing Array Contents}

CONCEPT: Individual array elements are processed like any other type of variable.
Processing array elements is no different than processing other variables. For example, the following statement multiplies hours [3] by the variable rate:
```

pay = hours[3] * rate;

```

And the following are examples of pre-increment and post-increment operations on array elements:
```

int score[5] = {7, 8, 9, 10, 11};
++score[2]; // Pre-increment operation on the value in score[2]
score[4]++; // Post-increment operation on the value in score[4]

```

NOTE: When using increment and decrement operators, be careful not to confuse the subscript with the array element. For example, the following statement decrements the variable count, but does nothing to the value in amount [count].
```

amount[count--];

```

To decrement the value stored in amount [count], use the following statement:
```

amount[count]--;

```

Program 7-13 demonstrates the use of array elements in a simple mathematical statement. A loop steps through each element of the array, using the elements to calculate the gross pay of five employees.

\section*{Program 7-13}
```

// This program stores, in an array, the hours worked by
// employees who all make the same hourly wage.
\#include <iostream>
\#include <iomanip>
using namespace std;
int main()
{
const int NUM_EMPLOYEES = 5; // Number of employees
int hours[NUM_EMPLOYEES]; // Array to hold hours
double payrate; // Hourly pay rate
double grossPay; // To hold the gross pay
// Input the hours worked.
cout << "Enter the hours worked by ";
cout << NUM_EMPLOYEES << " employees who all\n";
cout << "earn the same hourly rate.\n";
for (int index = 0; index < NUM_EMPLOYEES; index++)
{
cout << "Employee \#" << (index + 1) << ": ";
cin >> hours[index];
}
// Input the hourly rate for all employees.
cout << "Enter the hourly pay rate for all the employees: ";
cin >> payrate;
// Display each employee's gross pay.
cout << "Here is the gross pay for each employee:\n";
cout << fixed << showpoint << setprecision(2);
for (int index = 0; index < NUM_EMPLOYEES; index++)
{
grossPay = hours[index] * payrate;
cout << "Employee \#" << (index + 1);
cout << ": \$" << grossPay << endl;
}
return 0;
}

```

\section*{Program Output with Example Input Shown in Bold}

Enter the hours worked by 5 employees who all
earn the same hourly rate.
Employee \#1: 5 Enter
Employee \#2: 10 Enter
```

Program 7-13
(continued)

```
```

Employee \#3: 15 Enter

```
Employee #3: 15 Enter
Employee #4: 20 Enter
Employee #4: 20 Enter
Employee #5: 40 Enter
Employee #5: 40 Enter
Enter the hourly pay rate for all the employees: 12.75 Enter
Enter the hourly pay rate for all the employees: 12.75 Enter
Here is the gross pay for each employee:
Here is the gross pay for each employee:
Employee #1: $63.75
Employee #1: $63.75
Employee #2: $127.50
Employee #2: $127.50
Employee #3: $191.25
Employee #3: $191.25
Employee #4: $255.00
Employee #4: $255.00
Employee #5: $510.00
```

Employee \#5: \$510.00

```

The following statement in line 33 assigns the value of hours[index] times payRate to the grossPay variable:
```

grossPay = hours[index] * payRate;

```

Array elements may also be used in relational expressions. For example, the following if statement tests cost [20] to determine whether it is less than cost [0]:
```

if (cost[20] < cost[0])

```

And the following statement sets up a while loop to iterate as long as value[place] does not equal 0 :
```

while (value[place] != 0)

```

\section*{Thou Shall Not Assign}

The following code defines two integer arrays: newValues and oldValues. newValues is uninitialized, and oldValues is initialized with \(10,100,200\), and 300.
```

const int SIZE = 4;
int oldValues[SIZE] = {10, 100, 200, 300};
int newValues[SIZE];

```

At first glance, it might appear that the following statement assigns the contents of the array oldValues to newValues:
```

newValues = oldValues; // Wrong!

```

Unfortunately, this statement will not work. The only way to assign one array to another is to assign the individual elements in the arrays. Usually, this is best done with a loop, such as:
```

for (int count = 0; count < SIZE; count++)

```
    newValues[count] = oldValues[count];

The reason the assignment operator will not work with an entire array at once is complex, but important to understand. Anytime the name of an array is used without brackets and a subscript, it is seen as the array's beginning memory address. To illustrate this, consider the definition of the arrays newValues and oldValues above. Figure 7-12 depicts the two arrays in memory.

Figure 7-12 The newValues and oldValues arrays

In the figure, newValues is shown starting at memory address 8012 and oldValues is shown starting at 8024 . (Of course, these are just arbitrary addresses, picked for illustration purposes. In reality, the addresses would probably be different.) Table 7-2 shows various expressions that use the names of these arrays and their values.

Table 7-2 Array Expressions
\begin{tabular}{ll}
\hline Expression & Value \\
\hline oldValues[0] & 10 (Contents of Element 0 of oldValues) \\
oldValues[1] & 100 (Contents of Element 1 of oldValues) \\
oldValues[2] & 200 (Contents of Element 2 of oldValues) \\
oldValues[3] & 300 (Contents of Element 3 of oldValues) \\
newValues & 8012 (Memory Address of newValues) \\
oldValues & 8024 (Memory Address of oldValues) \\
\hline
\end{tabular}

Because the name of an array without the brackets and subscript stands for the array's starting memory address, the statement
```

newValues = oldValues;

```
is interpreted by C++ as
```

8012 = 8024;

```

The statement will not work, because you cannot change the starting memory address of an array.

\section*{Printing the Contents of an Array}

Suppose we have the following array definition:
```

const int SIZE = 5;
int numbers [SIZE] = {10, 20, 30, 40, 50};

```

You now know that an array's name is seen as the array's beginning memory address. This explains why the following statement cannot be used to display the contents of the numbers array.
```

cout << numbers << endl; //Wrong!

```

When this statement executes, cout will display the array's memory address, not the array's contents. You must use a loop to display the contents of each of the array's elements, as follows:
```

for (int count = 0; count < SIZE; count++)
cout << numbers[count] << endl;

```

In C++ 11, you can use the range-based for loop to display an array's contents, as shown here:
```

for (int val : numbers)

```
        cout << val << endl;

\section*{Summing the Values in a Numeric Array}

To sum the values in an array, you must use a loop with an accumulator variable. The loop adds the value in each array element to the accumulator. For example, assume the following statements appear in a program, and values have been stored in the units array:
```

const int NUM_UNITS = 24;
int units[NUM_UNITS];

```

The following code uses a regular for loop to add the values of each element in the array to the total variable. When the code is finished, total will contain the sum of the units array's elements.
```

int total = 0; // Initialize accumulator
for (int count = 0; count < NUM_UNITS; count++)
total += units[count];

```

In C++ 11, you can use the range-based for loop, as shown below. When the code is finished, total will contain the sum of the units array's elements.
```

int total = 0; // Initialize accumulator
for (int val : units)
total += val;

```

NOTE: The first statement in both of these code segments sets total to 0 . Recall from Chapter 5 that an accumulator variable must be set to 0 before it is used to keep a running total, or the sum will not be correct.

\section*{Getting the Average of the Values in a Numeric Array}

The first step in calculating the average of all the values in an array is to sum the values. The second step is to divide the sum by the number of elements in the array. Assume the following statements appear in a program, and values have been stored in the scores array:
```

const int NUM_SCORES = 10;
double scores[NUM_SCORES];

```

The following code calculates the average of the values in the scores array. When the code completes, the average will be stored in the average variable.
```

double total = 0; // Initialize accumulator
double average; // Will hold the average
for (int count = 0; count < NUM_SCORES; count++)
total += scores[count];
average = tota1 / NUM_SCORES;

```

Notice the last statement, which divides total by NUM_SCORES, is not inside the loop. This statement should only execute once, after the loop has finished its iterations.
In C++ 11, you can use the range-based for loop, as shown below. When the code completes, the average will be stored in the average variable.
```

double total = 0; // Initialize accumulator
double average; // Will hold the average
for (int val : scores)
total += val;
average = tota1 / NUM_SCORES;

```

\section*{Finding the Highest and Lowest Values in a Numeric Array}

The algorithms for finding the highest and lowest values in an array are very similar. First, let's look at code for finding the highest value in an array. Assume the following code exists in a program, and values have already been stored in the numbers array:
```

const int SIZE = 50;
int numbers[SIZE];

```

The code to find the highest value in the array is as follows:
```

int count;
int highest;
highest = numbers[0];
for (count = 1; count < SIZE; count++)
{
if (numbers[count] > highest)
highest = numbers[count];
}

```

First, we copy the value in the first array element to the variable highest. Then, the loop compares all of the remaining array elements, beginning at subscript 1 , to the value in highest. Each time it finds a value in the array that is greater than highest, it copies that value to highest. When the loop has finished, highest will contain the highest value in the array.

The following code finds the lowest value in the array. As you can see, it is nearly identical to the code for finding the highest value.
```

int count;
int lowest;
lowest = numbers[0];
for (count = 1; count < SIZE; count++)
{
if (numbers[count] < lowest)
lowest = numbers[count];
}

```

When the loop has finished, lowest will contain the lowest value in the array.

\section*{Partially Filled Arrays}

Sometimes you need to store a series of items in an array, but you do not know the number of items that there are. As a result, you do not know the exact number of elements needed
for the array. One solution is to make the array large enough to hold the largest possible number of items. This can lead to another problem, however. If the actual number of items stored in the array is less than the number of elements, the array will be only partially filled. When you process a partially filled array, you must only process the elements that contain valid data items.

A partially filled array is normally used with an accompanying integer variable that holds the number of items stored in the array. For example, suppose a program uses the following code to create an array with 100 elements, and an int variable named count that will hold the number of items stored in the array.
```

const int SIZE = 100;
int numbers[SIZE];
int count = 0;

```

Each time we add an item to the array, we must increment count. The following code demonstrates this:
```

int num;
cout << "Enter a number or -1 to quit: ";
cin >> num;
while (num != -1 \&\& count < SIZE)
{
count++;
numbers[count - 1] = num;
cout << "Enter a number or -1 to quit: ";
cin >> num;
}

```

Each iteration of this sentinel-controlled loop allows the user to enter a number to be stored in the array, or -1 to quit. The count variable is incremented then used to calculate the subscript of the next available element in the array. When the user enters -1 , or count exceeds 99 , the loop stops. The following code displays all of the valid items in the array:
```

for (int index = 0; index < count; index++)
{
cout << numbers[index] << endl;
}

```

Notice this code uses count to determine the maximum array subscript to use.
Program 7-14 shows how this technique can be used to read an unknown number of items from a file into an array. The program reads values from the file numbers.txt.

\section*{Program 7-14}
```

//This program reads data from a file into an array.
\#include <iostream>
\#include <fstream>
using namespace std;
int main()
{
const int ARRAY_SIZE = 100; // Array size
int numbers[ARRAY_SIZE]; // Array with 100 elements

```
```

    int count = 0; // Loop counter variable
    ifstream inputFile; // Input file stream object
    inputFile.open("numbers.txt"); // Open the file.
    // Read the numbers from the file into the array.
    // After this loop executes, the count variable will hold
    // the number of values that were stored in the array.
    while (count < ARRAY_SIZE && inputFile >> numbers[count])
        count++;
    // Close the file.
    inputFile.close();
    // Display the numbers read.
    cout << "The numbers are: ";
    for (int index = 0; index < count; index++)
        cout << numbers[index] << " ";
    cout << endl;
    return 0;
    }

```

\section*{Program Output}

The numbers are: \(\begin{array}{llllllllllll}47 & 89 & 65 & 36 & 12 & 25 & 17 & 8 & 62 & 10 & 87 & 62\end{array}\)

Look closer at the while loop that begins in line 18. It repeats as long as count is less than ARRAY_SIZE and the end of the file has not been encountered. The first part of the while loop's test expression, count < ARRAY_SIZE, prevents the loop from writing outside the array boundaries. Recall from Chapter 4 that the \&\& operator performs shortcircuit evaluation, so the second part of the while loop's test expression, inputFile >> values [count], will be executed only if count is less than ARRAY_SIZE.

\section*{Comparing Arrays}

We have already noted that you cannot simply assign one array to another array. You must assign each element of the first array to an element of the second array. In addition, you cannot use the \(==\) operator with the names of two arrays to determine whether the arrays are equal. For example, the following code appears to compare two arrays, but in reality it does not:
```

int firstArray[] = { 5, 10, 15, 20, 25 };
int secondArray[] = { 5, 10, 15, 20, 25 };
if (firstArray == secondArray) // This is a mistake.
cout << "The arrays are the same.\n";
else
cout << "The arrays are not the same.\n";

```

When you use the == operator with array names, the operator compares the beginning memory addresses of the arrays, not the contents of the arrays. The two array names in this code will obviously have different memory addresses. Therefore, the result of the expression firstArray \(==\) secondArray is false, and the code reports that the arrays are not the same.

To compare the contents of two arrays, you must compare the elements of the two arrays. For example, look at the following code:
```

const int SIZE = 5;
int firstArray[SIZE] = { 5, 10, 15, 20, 25 };
int secondArray[SIZE] = { 5, 10, 15, 20, 25 };
bool arraysEqua1 = true; // Flag variable
int count = 0; // Loop counter variable
// Determine whether the elements contain the same data.
while (arraysEqual \&\& count < SIZE)
{
if (firstArray[count] != secondArray[count])
arraysEqual = false;
count++;
}
if (arraysEqual)
cout << "The arrays are equal.\n";
else
cout << "The arrays are not equa1.\n";

```

This code determines whether firstArray and secondArray contain the same values. A bool variable, arraysEqua1, which is initialized to true, is used to signal whether the arrays are equal. Another variable, count, which is initialized to 0 , is used as a loop counter variable.

Then a while loop begins. The loop executes as long as arraysEqual is true and the counter variable count is less than SIZE. During each iteration, it compares a different set of corresponding elements in the arrays. When it finds two corresponding elements that have different values, the arraysEqual variable is set to false. After the loop finishes, an if statement examines the arraysEqual variable. If the variable is true, then the arrays are equal and a message indicating so is displayed. Otherwise, they are not equal, so a different message is displayed.

\subsection*{7.6 Focus on Software Engineering: Using Parallel Arrays}

CONCEPT: By using the same subscript, you can build relationships between data stored in two or more arrays.

Sometimes it's useful to store related data in two or more arrays. It's especially useful when the related data is of unlike types. For example, Program 7-15 is another variation of the payroll program. It uses two arrays: one to store the hours worked by each employee (as ints), and another to store each employee's hourly pay rate (as doubles).

\section*{Program 7-15}
```

1 // This program uses two parallel arrays: one for hours
2 // worked and one for pay rate.
3 \#include <iostream>

```
```

\#include <iomanip>
using namespace std;
int main()
{
const int NUM_EMPLOYEES = 5; // Number of employees
int hours[NUM_EMPLOYEES]; // Holds hours worked
double payRate[NUM_EMPLOYEES]; // Holds pay rates
// Input the hours worked and the hourly pay rate.
cout << "Enter the hours worked by " << NUM_EMPLOYEES
<< " employees and their\n"
<< "hourly pay rates.\n";
for (int index = 0; index < NUM_EMPLOYEES; index++)
{
cout << "Hours worked by employee \#" << (index+1) << ": ";
cin >> hours[index];
cout << "Hourly pay rate for employee \#" << (index+1) << ": ";
cin >> payRate[index];
}
// Display each employee's gross pay.
cout << "Here is the gross pay for each employee:\n";
cout << fixed << showpoint << setprecision(2);
for (int index = 0; index < NUM_EMPLOYEES; index++)
{
double grossPay = hours[index] * payRate[index];
cout << "Employee \#" << (index + 1);
cout << ": \$" << grossPay << endl;
}
return 0;
}

```

\section*{Program Output with Example Input Shown in Bold}

Enter the hours worked by 5 employees and their hourly pay rates.
Hours worked by employee \#1: 10 Enter
Hourly pay rate for employee \#1: 9.75 Enter
Hours worked by employee \#2: 15 Enter
Hourly pay rate for employee \#2: 8.62 Enter
Hours worked by employee \#3: 20 Enter
Hourly pay rate for employee \#3: 10.50 Enter
Hours worked by employee \#4: 40 Enter
Hourly pay rate for employee \#4: 18.75 Enter
Hours worked by employee \#5: 40 Enter
Hourly pay rate for employee \#5: 15.65 Enter
Here is the gross pay for each employee:
Employee \#1: \$97.50
Employee \#2: \$129.30
Employee \#3: \$210.00
Employee \#4: \$750.00
Employee \#5: \$626.00

Notice in the loops the same subscript is used to access both arrays. That's because the data for one employee is stored in the same relative position in each array. For example, the hours worked by employee \#1 are stored in hours [0], and the same employee's pay rate is stored in payRate[0]. The subscript relates the data in both arrays.

This concept is illustrated in Figure 7-13.

Figure 7-13 Parallel arrays

\section*{Checkpoint}
7.10 Given the following array definition:
```

int values[] = {2, 6, 10, 14};

```

What does each of the following display?
A) cout << values[2];
B) cout \(\ll++\) values [0];
C) cout << values[1]++;
D) \(x=2\); cout << values[++x];
7.11 Given the following array definition:
```

int nums[5] = {1, 2, 3};

```

What will the following statement display?
```

cout << nums[3];

```
7.12 What is the output of the following code? (You may need to use a calculator.)
```

double balance[5] = {100.0, 250.0, 325.0, 500.0, 1100.0};
const double INTRATE = 0.1;
cout << fixed << showpoint << setprecision(2);
for (int count = 0; count < 5; count++)
cout << (balance[count] * INTRATE) << endl;

```
7.13 What is the output of the following code? (You may need to use a calculator.)
```

const int SIZE = 5;
int time[SIZE] = {1, 2, 3, 4, 5},
speed[SIZE] = {18, 4, 27, 52, 100},
dist[SIZE];
for (int count = 0; count < SIZE; count++)
dist[count] = time[count] * speed[count];
for (int count = 0; count < SIZE; count++)
{
cout << time[count] << " ";
cout << speed[count] << " ";
cout << dist[count] << endl;
}

```

\subsection*{7.7 Arrays as Function Arguments}

CONCEPT: To pass an array as an argument to a function, pass the name of the array.

VideoNote
Passing an Array to a Function

Quite often, you'll want to write functions that process the data in arrays. For example, functions could be written to put values in an array, display an array's contents on the screen, total all of an array's elements, or calculate their average. Usually, such functions accept an array as an argument.

When a single element of an array is passed to a function, it is handled like any other variable. For example, Program 7-16 shows a loop that passes one element of the array numbers to the function showValue each time the loop iterates.

\section*{Program 7-16}
```

// This program demonstrates that an array element is passed
// to a function like any other variable.
\#include <iostream>
using namespace std;
void showValue(int); // Function prototype
int main()
{
const int SIZE = 8;
int numbers[SIZE] = {5, 10, 15, 20, 25, 30, 35, 40};
for (int index = 0; index < SIZE; index++)
showValue(numbers[index]);
return 0;
}

```
```

Program 7-16 (continued)
17
|/**********************************************
// Definition of function showValue. *
// This function accepts an integer argument. *
// The value of the argument is displayed. *
//*************************************************
void showValue(int num)
{
cout << num << " ";
}

```

\section*{Program Output}
\(\begin{array}{llllllll}5 & 10 & 15 & 20 & 25 & 30 & 35 & 40\end{array}\)

Each time showValue is called in line 14 , a copy of an array element is passed into the parameter variable num. The showValue function simply displays the contents of num and doesn't work directly with the array element itself. (In other words, the array element is passed by value.)
If the function were written to accept the entire array as an argument, however, the parameter would be set up differently. In the following function definition, the parameter nums is followed by an empty set of brackets. This indicates that the argument will be an array, not a single value.
```

void showValues(int nums[], int size)
{
for (int index = 0; index < size; index++)
cout << nums[index] << " ";
cout << endl;
}

```

The reason there is no size declarator inside the brackets of nums is because nums is not actually an array. It's a special variable that can accept the address of an array. When an entire array is passed to a function, it is not passed by value, but passed by reference. Imagine the CPU time and memory that would be necessary if a copy of a 10,000 -element array were created each time it was passed to a function! Instead, only the starting memory address of the array is passed. Program 7-17 shows the function showValues in use.

NOTE: Notice in the function prototype, empty brackets appear after the data type of the array parameter. This indicates that showValues accepts the address of an array of integers.

\section*{Program 7-17}
```

// This program demonstrates an array being passed to a function.
\#include <iostream>
using namespace std;
void showValues(int [], int); // Function prototype
int main()
{
const int ARRAY_SIZE = 8;
int numbers[ARRAY_SIZE] = {5, 10, 15, 20, 25, 30, 35, 40};
showValues(numbers, ARRAY_SIZE);
return 0;
}
|/*****************************************************
// Definition of function showValue.
// This function accepts an array of integers and
// the array's size as its arguments. The contents *
// of the array are displayed.
||****************************************************
void showValues(int nums[], int size)
{
for (int index = 0; index < size; index++)
cout << nums[index] << " ";
cout << endl;
}

```

\section*{Program Output}

510152025303540

In Program 7-17, the function showValues is called in the following statement that appears in line 12 :
showValues(numbers, ARRAY_SIZE);
The first argument is the name of the array. Remember, in C++ the name of an array without brackets and a subscript is actually the beginning address of the array. In this function call, the address of the numbers array is being passed as the first argument to the function. The second argument is the size of the array.

In the showValues function, the beginning address of the numbers array is copied into the nums parameter variable. The nums variable is then used to reference the numbers array. Figure 7-14 illustrates the relationship between the numbers array and the nums parameter variable. When the contents of nums [0] are displayed, it is actually the contents of numbers [0] that appear on the screen.

Figure 7-14 Relationship between the numbers array and the nums parameter
numbers Array of eight integers

NOTE: Although nums is not a reference variable, it works like one.

The nums parameter variable in the showValues function can accept the address of any integer array, and can be used to reference that array. So, we can use the showValues function to display the contents of any integer array by passing the name of the array and its size as arguments. Program 7-18 uses the function to display the contents of two different arrays.

\section*{Program 7-18}
```

// This program demonstrates the showValues function being
// used to display the contents of two arrays.
\#include <iostream>
using namespace std;
void showValues(int [], int); // Function prototype
int main()
{
const int SIZE1 = 8; // Size of set1 array
const int SIZE2 = 5; // Size of set2 array
int set1[SIZE1] = {5, 10, 15, 20, 25, 30, 35, 40};
int set2[SIZE2] = {2, 4, 6, 8, 10};
// Pass set1 to showValues.
showValues(set1, SIZE1);
// Pass set2 to showValues.
showValues(set2, SIZE2);
return 0;
}
//***************************************************
// Definition of function showValues. *
// This function accepts an array of integers and *
// the array's size as its arguments. The contents *
// of the array are displayed.
//**************************************************

```
```

void showValues(int nums[], int size)
{
for (int index = 0; index < size; index++)
cout << nums[index] << " ";
cout << endl;
}

```

\section*{Program Output}
```

5 10 15 20 25 30 35 40

```
246810

Recall from Chapter 6 that when a reference variable is used as a parameter, it gives the function access to the original argument. Any changes made to the reference variable are actually performed on the argument referenced by the variable. Array parameters work very much like reference variables. They give the function direct access to the original array. Any changes made with the array parameter are actually made on the original array used as the argument. The function doub1eArray in Program 7-19 uses this capability to double the contents of each element in the array.

\section*{Program 7-19}
```

// This program uses a function to double the value of
// each element of an array.
\#include <iostream>
using namespace std;
// Function prototypes
void doubleArray(int [], int);
void showValues(int [], int);
int main()
{
const int ARRAY_SIZE = 7;
int set[ARRAY_SIZE] = {1, 2, 3, 4, 5, 6, 7};
// Display the initial values.
cout << "The array's values are:\n";
showValues(set, ARRAY_SIZE);
// Double the values in the array.
doubleArray(set, ARRAY_SIZE);
// Display the resulting values.
cout << "After calling doubleArray the values are:\n";
showValues(set, ARRAY_SIZE);
return 0;
}

```

\section*{Program 7-19 (continued)}
```

//******************************************************
// Definition of function doubleArray
// This function doubles the value of each element *
// in the array passed into nums. The value passed *
// into size is the number of elements in the array. *
|/**********************************************************
void doubleArray(int nums[], int size)
{
for (int index = 0; index < size; index++)
nums[index] *= 2;
}
//****************************************************
// Definition of function showValues.
// This function accepts an array of integers and *
// the array's size as its arguments. The contents *
// of the array are displayed.
//*****************************************************
void showValues(int nums[], int size)
{
for (int index = 0; index < size; index++)
cout << nums[index] << " ";
cout << endl;
}

```

\section*{Program Output}

The array's values are:
1234567
After calling doubleArray the values are:
2468101214

\section*{Using const Array Parameters}

Sometimes you want a function to be able to modify the contents of an array that is passed to it as an argument, and sometimes you don't. You can prevent a function from making changes to an array argument by using the const key word in the parameter declaration. Here is an example of the showValues function, shown previously, rewritten with a const array parameter:
```

void showValues(const int nums[], int size)
{
for (int index = 0; index < size; index++)
cout << nums[index] << " ";
cout << endl;
}

```

When an array parameter is declared as const, the function is not allowed to make changes to the array's contents. If a statement in the function attempts to modify the array, an error
will occur at compile time. As a precaution, you should always use const array parameters in any function that is not intended to modify its array argument. That way, the function will fail to compile if you inadvertently write code in it that modifies the array.

\section*{Some Useful Array Functions}

Section 7.5 introduced you to algorithms such as summing an array and finding the highest and lowest values in an array. Now that you know how to pass an array as an argument to a function, you can write general purpose functions that perform those operations. The following In the Spotlight section shows an example.

\section*{In the Spotlight:}

\section*{Processing an Array}

Dr. LaClaire gives four exams during the semester in her chemistry class. At the end of the semester, she drops each student's lowest test score before averaging the scores. She has asked you to write a program that will read a student's four test scores as input, and calculate the average with the lowest score dropped. Here is the pseudocode algorithm that you developed:

Read the student's four test scores.
Calculate the total of the scores.
Find the lowest score.
Subtract the lowest score from the total. This gives the adjusted total.
Divide the adjusted total by 3. This is the average.
Display the average.
Program 7-20 shows the program, which is modularized. Rather than presenting the entire program at once, let's first examine the main function, then each additional function separately. Here is the first part of the program, including the main function:

\section*{Program 7-20 (main function)}
```

1 // This program gets a series of test scores and
2 /l calculates the average of the scores with the
3 // lowest score dropped.
4 \#include <iostream>
5 \#include <iomanip>
6 using namespace std;
7
8 // Function prototypes
9 void getTestScores(double[], int);
1 0 double getTotal(const double[], int);
1 1 double getLowest(const double[], int);

```
12

\section*{Program 7-20 (continued)}
```

int main()
{
const int SIZE = 4; // Array size
double testScores[SIZE], // Array of test scores
total, // Total of the scores
lowestScore, // Lowest test score
average; // Average test score
// Set up numeric output formatting.
cout << fixed << showpoint << setprecision(1);
// Get the test scores from the user.
getTestScores(testScores, SIZE);
// Get the total of the test scores.
total = getTotal(testScores, SIZE);
// Get the lowest test score.
lowestScore = getLowest(testScores, SIZE);
// Subtract the lowest score from the total.
total -= lowestScore;
// Calculate the average. Divide by 3 because
// the lowest test score was dropped.
average = total / (SIZE - 1);
// Display the average.
cout << "The average with the lowest score "
<< "dropped is " << average << ".\n";
return 0;
}

```

Lines 15 through 19 define the following items:
- SIZE—an int constant that is used as an array size declarator
- testScores-a double array to hold the test scores
- t0ta1—a doub1e variable that will hold the test score totals
- lowestScore-a double variable that will hold the lowest test score
- average-a double variable that will hold the average of the test scores

Line 25 calls the getTestScores function, passing the testScores array and the value of the SIZE constant as arguments. The function gets the test scores from the user and stores them in the array.

Line 28 calls the getTotal function, passing the testScores array and the value of the SIZE constant as arguments. The function returns the total of the values in the array. This value is assigned to the total variable.

Line 31 calls the getLowest function, passing the testScores array and the value of the SIZE constant as arguments. The function returns the lowest value in the array. This value is assigned to the lowestScore variable.

Line 34 subtracts the lowest test score from the total variable. Then, line 38 calculates the average by dividing total by SIZE - 1 . (The program divides by SIZE - 1 because the lowest test score was dropped.) Lines 41 and 42 display the average.

The getTestScores function appears next, as shown here:

\section*{Program 7-20 (getTestScores function)}
```

1/
// The getTestScores function accepts an array and its size *
// as arguments. It prompts the user to enter test scores, *
// which are stored in the array.
||**************************************************************
void getTestScores(double scores[], int size)
{
// Loop counter
int index;
// Get each test score.
for(index = 0; index <= size - 1; index++)
{
cout << "Enter test score number "
<< (index + 1) << ": ";
cin >> scores[index];
}
}

```

The getTestScores function has two parameters:
- scores[]-A double array
- size-An int specifying the size of the array that is passed into the scores[] parameter

The purpose of this function is to get a student's test scores from the user and store them in the array that is passed as an argument into the scores[] parameter.

The getTotal function appears next, as shown here:

\section*{Program 7-20 (getTotal function)}
\begin{tabular}{|c|c|}
\hline 67 & 1/* \\
\hline 68 & // The getTotal function accepts a double array \\
\hline 69 & // and its size as arguments. The sum of the array's \\
\hline 70 & // elements is returned as a double. \\
\hline 71 & /1* \\
\hline
\end{tabular}

\section*{Program 7-20 (continued)}
```

double getTotal(const double numbers[], int size)
{
double total = 0; // Accumulator
// Add each element to total.
for (int count = 0; count < size; count++)
total += numbers[count];
// Return the total.
return total;
}

```

The getTotal function has two parameters:
- numbers[]-A const double array
- size-An int specifying the size of the array that is passed into the numbers[] parameter

This function returns the total of the values in the array that is passed as an argument into the numbers [] parameter.

The getLowest function appears next, as shown here:

\section*{Program 7-20 (getLowest function)}
```

//***********************************************************
// The getLowest function accepts a double array and *
// its size as arguments. The lowest value in the
// array is returned as a double.
||******************************************************
double getLowest(const double numbers[], int size)
{
double lowest; // To hold the lowest value
// Get the first array's first element.
lowest = numbers[0];
// Step through the rest of the array. When a
// value less than lowest is found, assign it
// to lowest.
for (int count = 1; count < size; count++)
{
if (numbers[count] < lowest)
lowest = numbers[count];
}
// Return the lowest value.
return lowest;
}

```

The getLowest function has two parameters:
- numbers[]-A const double array
- size-An int specifying the size of the array that is passed into the numbers[] parameter

This function returns the lowest value in the array that is passed as an argument into the numbers [] parameter. Here is an example of the program's output:

\section*{Program 7-20}

Program Output with Example Input Shown in Bold
```

Enter test score number 1: 92 Enter
Enter test score number 2: 67 Enter
Enter test score number 3: 75 Enter
Enter test score number 4: 88 Enter
The average with the lowest score dropped is 85.0.

```

\section*{Checkpoint}
7.14 Given the following array definitions:
```

double array1[4] = {1.2, 3.2, 4.2, 5.2};
double array2[4];

```

Will the following statement work? If not, why?
```

array2 = array1;

```
7.15 When an array name is passed to a function, what is actually being passed?
7.16 When used as function arguments, are arrays passed by value?
7.17 What is the output of the following program? (You may need to consult the ASCII table in Appendix A.)
```

\#include <iostream>
using namespace std;
// Function prototypes
void fillArray(char [], int);
void showArray(const char [], int);
int main ()
{
const int SIZE = 8;
char prodCode[SIZE] = {'0', '0', '0', '0', '0', '0', '0', '0'};
fillArray(prodCode, SIZE);
showArray(prodCode, SIZE);
return 0;
}
// Definition of function fillArray.
// (Hint: 65 is the ASCII code for 'A')

```
```

void fillArray(char arr[], int size)
{
char code = 65;
for (int k = 0; k < size; code++, k++)
arr[k] = code;
}
// Definition of function showArray.
void showArray(const char codes[], int size)
{
for (int k = 0; k < size; k++)
cout << codes[k];
cout << endl;
}

```
7.18 The following program skeleton, when completed, will ask the user to enter 10 integers, which are stored in an array. The function avgArray, which you must write, is to calculate and return the average of the numbers entered.
```

\#include <iostream>
using namespace std;
// Write your function prototype here
int main()
{
const int SIZE = 10;
int userNums[SIZE];
cout << "Enter 10 numbers: ";
for (int count = 0; count < SIZE; count++)
{
cout << "\#" << (count + 1) << " ";
cin >> userNums[count];
}
cout << "The average of those numbers is ";
cout << avgArray(userNums, SIZE) << endl;
return 0;
}
//
// Write the function avgArray here.
|/

```

\subsection*{7.8 Two-Dimensional Arrays}

CONCEPT: A two-dimensional array is like several identical arrays put together. It is useful for storing multiple sets of data.

An array is useful for storing and working with a set of data. Sometimes, though, it's necessary to work with multiple sets of data. For example, in a grade-averaging program, a teacher might record all of one student's test scores in an array of doubles. If the teacher
has 30 students, that means he or she will need 30 arrays of doubles to record the scores for the entire class. Instead of defining 30 individual arrays, however, it would be better to define a two-dimensional array.

The arrays you have studied so far are one-dimensional arrays. They are called onedimensional because they can only hold one set of data. Two-dimensional arrays, which are sometimes called \(2 D\) arrays, can hold multiple sets of data. It's best to think of a two-dimensional array as having rows and columns of elements, as shown in Figure 7-15. This figure shows an array of test scores, having three rows and four columns.

Figure 7-15 Two-dimensional array
\begin{tabular}{l|l|l|l|l|} 
& \multicolumn{1}{c}{ Column 0 } & \multicolumn{2}{c}{ Column 1 } & \multicolumn{2}{c}{ Column 2 } & \multicolumn{1}{c}{ Column 3 } \\
\cline { 2 - 6 } Row 0 & scores[0] [0] & scores[0] [1] & scores [0] [2] & scores [0] [3] \\
\cline { 2 - 6 } Row 1 & scores[1] [0] & scores[1] [1] & scores[1] [2] & scores[1] [3] \\
\cline { 2 - 6 } Row 2 & scores[2] [0] & scores[2] [1] & scores[2] [2] & scores[2] [3] \\
\cline { 2 - 6 } & & & &
\end{tabular}

The array depicted in Figure 7-15 has three rows (numbered 0 through 2) and four columns (numbered 0 through 3). There are a total of 12 elements in the array.

To define a two-dimensional array, two size declarators are required. The first one is for the number of rows, and the second one is for the number of columns. Here is an example definition of a two-dimensional array with three rows and four columns:

The first size declarator specifies the number of rows, and the second size declarator specifies the number of columns. Notice each number is enclosed in its own set of brackets.

When processing the data in a two-dimensional array, each element has two subscripts: one for its row, and another for its column. In the scores array defined above, the elements in row 0 are referenced as
```

scores[0][0]

```
scores [0][1]
scores[0][2]
scores[0][3]

The elements in row 1 are
```

scores[1][0]

```
scores[1][1]
scores[1][2]
scores[1][3]

And the elements in row 2 are
scores[2][0]
scores[2][1]
scores[2][2]
scores[2][3]

The subscripted references are used in a program just like the references to elements in a single-dimensional array, except now you use two subscripts. The first subscript represents the row position, and the second subscript represents the column position. For example, the following statement assigns the value 92.25 to the element at row 2 , column 1 of the scores array:
```

scores[2][1] = 92.25;

```

And the following statement displays the element at row 0 , column 2 :
```

cout << scores[0][2];

```

Programs that step through each element of a two-dimensional array usually do so with nested loops. Program 7-21 is an example.

\section*{Program 7-21}
```

// This program demonstrates a two-dimensional array.

```
// This program demonstrates a two-dimensional array.
#include <iostream>
#include <iostream>
#include <iomanip>
#include <iomanip>
using namespace std;
using namespace std;
int main()
int main()
{
{
    const int NUM_DIVS = 3; // Number of divisions
    const int NUM_DIVS = 3; // Number of divisions
    const int NUM_QTRS = 4; // Number of quarters
    const int NUM_QTRS = 4; // Number of quarters
    double sales[NUM_DIVS][NUM_QTRS]; // Array with 3 rows and 4 columns.
    double sales[NUM_DIVS][NUM_QTRS]; // Array with 3 rows and 4 columns.
    double totalSales = 0; // To hold the total sales.
    double totalSales = 0; // To hold the total sales.
    int div, qtr; // Loop counters.
    int div, qtr; // Loop counters.
    cout << "This program will calculate the total sales of\n";
    cout << "This program will calculate the total sales of\n";
    cout << "all the company's divisions.\n";
    cout << "all the company's divisions.\n";
    cout << "Enter the following sales information:\n\n";
    cout << "Enter the following sales information:\n\n";
    // Nested loops to fill the array with quarterly
    // Nested loops to fill the array with quarterly
    // sales figures for each division.
    // sales figures for each division.
    for (div = 0; div < NUM_DIVS; div++)
    for (div = 0; div < NUM_DIVS; div++)
    {
    {
        for (qtr = 0; qtr < NUM_QTRS; qtr++)
        for (qtr = 0; qtr < NUM_QTRS; qtr++)
        {
        {
            cout << "Division " << (div + 1);
            cout << "Division " << (div + 1);
            cout << ", Quarter " << (qtr + 1) << ": $";
            cout << ", Quarter " << (qtr + 1) << ": $";
            cin >> sales[div][qtr];
            cin >> sales[div][qtr];
        }
        }
        cout << endl; // Print blank line.
        cout << endl; // Print blank line.
    }
    }
    // Nested loops used to add all the elements.
    // Nested loops used to add all the elements.
    for (div = 0; div < NUM_DIVS; div++)
    for (div = 0; div < NUM_DIVS; div++)
    {
    {
    for (qtr = 0; qtr < NUM_QTRS; qtr++)
    for (qtr = 0; qtr < NUM_QTRS; qtr++)
        totalSales += sales[div][qtr];
        totalSales += sales[div][qtr];
    }
```

    }
    ```
```

    cout << fixed << showpoint << setprecision(2);
    39 cout << "The total sales for the company are: \$";
40 cout << totalSales << endl;
41 return 0;

```
\(42\}\)

\section*{Program Output with Example Input Shown in Bold}

This program will calculate the total sales of all the company's divisions.
Enter the following sales data:
Division 1, Quarter 1: \$31569.45 Enter
Division 1, Quarter 2: \$29654.23 Enter
Division 1, Quarter 3: \$32982.54 Enter
Division 1, Quarter 4: \$39651.21 Enter
Division 2, Quarter 1: \$56321.02 Enter
Division 2, Quarter 2: \$54128.63 Enter
Division 2, Quarter 3: \$41235.85 Enter
Division 2, Quarter 4: \$54652.33 Enter
Division 3, Quarter 1: \$29654.35 Enter
Division 3, Quarter 2: \$28963.32 Enter
Division 3, Quarter 3: \$25353.55 Enter
Division 3, Quarter 4: \$32615.88 Enter
The total sales for the company are: \$456782.34

When initializing a two-dimensional array, it helps to enclose each row's initialization list in a set of braces. Here is an example:
```

int hours[3][2] = {{8, 5}, {7, 9}, {6, 3}};

```

The same definition could also be written as:
```

int hours[3][2] = {{8, 5},
{7, 9},
{6, 3}};

```

In either case, the values are assigned to hours in the following manner:
```

hours[0][0] is set to 8
hours[0][1] is set to 5
hours[1][0] is set to 7
hours[1][1] is set to 9
hours[2][0] is set to 6
hours[2][1] is set to 3

```

Figure 7-16 illustrates the initialization.
Figure 7-16 Two-dimensional array initialization
\begin{tabular}{l|c|c|}
\multicolumn{1}{c}{} & \multicolumn{1}{c}{ Column 0 } & \multicolumn{1}{c}{ Column 1 } \\
\cline { 2 - 3 } Row 0 & 8 & 5 \\
\cline { 2 - 3 } Row 1 & 7 & 9 \\
\cline { 2 - 3 } Row 2 & 6 & 3 \\
\cline { 2 - 3 } & &
\end{tabular}

The extra braces that enclose each row's initialization list are optional. Both of the following statements perform the same initialization:
```

int hours[3][2] = {{8, 5}, {7, 9}, {6, 3}};
int hours[3][2] = {8, 5, 7, 9, 6, 3};

```

Because the extra braces visually separate each row, however, it's a good idea to use them. In addition, the braces give you the ability to leave out initializers within a row without omitting the initializers for the rows that follow it. For instance, look at the following array definition:
```

int table[3][2] = {{1}, {3, 4}, {5}};

```
table[0][0] is initialized to 1 , table[1][0] is initialized to 3 , table[1][1] is initialized to 4, and table[2][0] is initialized to 5. table[0][1] and table[2][1] are not initialized. Because some of the array elements are initialized, these two initialized elements are automatically set to zero.

\section*{Passing Two-Dimensional Arrays to Functions}

Program 7-22 demonstrates passing a two-dimensional array to a function. When a twodimensional array is passed to a function, the parameter type must contain a size declarator for the number of columns. Here is the header for the function showArray, from Program 7-22:
```

void showArray(const int numbers[][COLS], int rows)

```

COLS is a global named constant that is set to 4 . The function can accept any two-dimensional integer array, as long as it consists of four columns. In the program, the contents of two separate arrays are displayed by the function.

\section*{Program 7-22}
```

// This program demonstrates accepting a 2D array argument.
\#include <iostream>
\#include <iomanip>
using namespace std;
// Global constants
const int COLS = 4; // Number of columns in each array
const int TBL1_ROWS = 3; // Number of rows in table1
const int TBL2_ROWS = 4; // Number of rows in table2
void showArray(const int [][COLS], int); // Function prototype
int main()
{
int table1[TBL1_ROWS][COLS] = {{1, 2, 3, 4},
{5, 6, 7, 8},
{9, 10, 11, 12}};
int table2[TBL2_ROWS][COLS] = {{10, 20, 30, 40},
{50, 60, 70, 80},
{90, 100, 110, 120},
{130, 140, 150, 160}};

```
```

    cout << "The contents of table1 are:\n";
    showArray(table1, TBL1_ROWS);
    cout << "The contents of table2 are:\n";
    showArray(tab1e2, TBL2_ROWS);
    return 0;
    }
//*********************************************************************
// Function Definition for showArray
// The first argument is a two-dimensional int array with COLS
// columns. The second argument, rows, specifies the number of
// rows in the array. The function displays the array's contents.
//*******************************************************************
void showArray(const int numbers[][COLS], int rows)
{
for (int x = 0; x < rows; x++)
{
for (int y = 0; y < COLS; y++)
{
cout << setw(4) << numbers[x][y] << " ";
}
cout << endl;
}
}

```

\section*{Program Output}

The contents of table1 are:
\begin{tabular}{llll}
1 & 2 & 3 & 4
\end{tabular}
\(\begin{array}{llll}5 & 6 & 7 & 8\end{array}\)
\(\begin{array}{llll}9 & 10 & 11 & 12\end{array}\)
The contents of table2 are:
\(\begin{array}{llll}10 & 20 & 30 & 40\end{array}\)
\(\begin{array}{llll}50 & 60 & 70 & 80\end{array}\)
\(90 \quad 100110120\)
130140150160

C++ requires the columns to be specified in the function prototype and header because of the way two-dimensional arrays are stored in memory. One row follows another, as shown in Figure 7-17.

Figure 7-17 Memory organization of a two-dimensional array

When the compiler generates code for accessing the elements of a two-dimensional array, it needs to know how many bytes separate the rows in memory. The number of columns is a critical factor in this calculation.

\section*{Summing All the Elements of a Two-Dimensional Array}

To sum all the elements of a two-dimensional array, you can use a pair of nested loops to add the contents of each element to an accumulator. The following code is an example:
```

const int NUM_ROWS = 5; // Number of rows
const int NUM_COLS = 5; // Number of columns
int total = 0; // Accumulator
int numbers[NUM_ROWS][NUM_COLS] = {{2, 7, 9, 6, 4},
{6, 1, 8, 9, 4},
{4, 3, 7, 2, 9},
{9, 9, 0, 3, 1},
{6, 2, 7, 4, 1}};
// Sum the array elements.
for (int row = 0; row < NUM_ROWS; row++)
{
for (int col = 0; col < NUM_COLS; col++)
tota1 += numbers[row][col];
}
// Display the sum.
cout << "The total is " << total << endl;

```

\section*{Summing the Rows of a Two-Dimensional Array}

Sometimes you may need to calculate the sum of each row in a two-dimensional array. For example, suppose a two-dimensional array is used to hold a set of test scores for a set of students. Each row in the array is a set of test scores for one student. To get the sum of a student's test scores (perhaps so an average may be calculated), you use a loop to add all the elements in one row. The following code shows an example.
```

const int NUM_STUDENTS = 3; // Number of students
const int NUM_SCORES = 5; // Number of test scores
double tota1; // Accumulator is set in the loops
double average; // To hold each student's average
double scores[NUM_STUDENTS][NUM_SCORES] = {{88, 97, 79, 86, 94},
{86, 91, 78, 79, 84},
{82, 73, 77, 82, 89}};
// Get each student's average score.
for (int row = 0; row < NUM_STUDENTS; row++)
{
// Set the accumulator.
total = 0;
// Sum a row.
for (int col = 0; col < NUM_SCORES; col++)
tota1 += scores[row][col];
// Get the average.
average = total / NUM_SCORES;
// Display the average.
cout << "Score average for student "
<< (row + 1) << " is " << average <<endl;
}

```

Notice the total variable, which is used as an accumulator, is set to zero just before the inner loop executes. This is because the inner loop sums the elements of a row and stores the sum in total. Therefore, the total variable must be set to zero before each iteration of the inner loop.

\section*{Summing the Columns of a Two-Dimensional Array}

Sometimes you may need to calculate the sum of each column in a two-dimensional array. In the previous example, a two-dimensional array is used to hold a set of test scores for a set of students. Suppose you wish to calculate the class average for each of the test scores. To do this, you calculate the average of each column in the array. This is accomplished with a set of nested loops. The outer loop controls the column subscript, and the inner loop controls the row subscript. The inner loop calculates the sum of a column, which is stored in an accumulator. The following code demonstrates this:
```

const int NUM_STUDENTS = 3; // Number of students
const int NUM_SCORES = 5; // Number of test scores
double total; // Accumulator is set in the loops
double average; // To hold each score's class average
double scores[NUM_STUDENTS][NUM_SCORES] = {{88, 97, 79, 86, 94},
{86, 91, 78, 79, 84},
{82, 73, 77, 82, 89}};
// Get the class average for each score.
for (int col = 0; col < NUM_SCORES; col++)
{
// Reset the accumulator.
tota1 = 0;
// Sum a column.
for (int row = 0; row < NUM_STUDENTS; row++)
tota1 += scores[row][col];
// Get the average.
average = total / NUM_STUDENTS;
// Display the class average.
cout << "Class average for test " << (col + 1)
<< " is " << average << endl;
}

```

\subsection*{7.9 Arrays with Three or More Dimensions}

CONCEPT: C++ does not limit the number of dimensions that an array may have. It is possible to create arrays with multiple dimensions, to model data that occur in multiple sets.

C++ allows you to create arrays with virtually any number of dimensions. Here is an example of a three-dimensional array definition:
```

double seats[3][5][8];

```

This array can be thought of as three sets of five rows, with each row containing eight elements. The array might be used to store the prices of seats in an auditorium, where there are eight seats in a row, five rows in a section, and a total of three sections.

Figure 7-18 illustrates the concept of a three-dimensional array as "pages" of twodimensional arrays.

Figure 7-18 A three-dimensional array

Arrays with more than three dimensions are difficult to visualize, but can be useful in some programming problems. For example, in a factory warehouse where cases of widgets are stacked on pallets, an array with four dimensions could be used to store a part number for each widget. The four subscripts of each element could represent the pallet number, case number, row number, and column number of each widget. Similarly, an array with five dimensions could be used if there were multiple warehouses.

NOTE: When writing functions that accept multi-dimensional arrays as arguments, all but the first dimension must be explicitly stated in the parameter list.

\section*{Checkpoint}
7.19 Define a two-dimensional array of ints named grades. It should have 30 rows and 10 columns.
7.20 How many elements are in the following array?
double sales[6][4];
7.21 Write a statement that assigns the value 56893.12 to the first column of the first row of the array defined in Question 7.20.
7.22 Write a statement that displays the contents of the last column of the last row of the array defined in Question 7.20.
7.23 Define a two-dimensional array named settings large enough to hold the table of data below. Initialize the array with the values in the table.
\begin{tabular}{|l|l|l|l|c|}
\hline 12 & 24 & 32 & 21 & 42 \\
\hline 14 & 67 & 87 & 65 & 90 \\
\hline 19 & 1 & 24 & 12 & 8 \\
\hline
\end{tabular}
7.24 Fill in the table below so that it shows the contents of the following array:
```

int table[3][4] = {{2, 3}, {7, 9, 2}, {1}};

```
\begin{tabular}{|l|l|l|l|l|}
\hline & & & & \\
\hline & & & & \\
\hline & & & & \\
\hline
\end{tabular}
7.25 Write a function called displayArray7. The function should accept a twodimensional array as an argument and display its contents on the screen. The function should work with any of the following arrays:
```

int hours[5][7];
int stamps[8][7];
int autos[12][7];
int cats[50][7];

```
7.26 A video rental store keeps DVDs on 50 racks with 10 shelves each. Each shelf holds 25 DVDs. Define a three-dimensional array large enough to represent the store's storage system.

\subsection*{7.10 Focus on Problem Solving and Program Design: A Case Study}

The National Commerce Bank has hired you as a contract programmer. Your first assignment is to write a function that will be used by the bank's automated teller machines (ATMs) to validate a customer's personal identification number (PIN).

Your function will be incorporated into a larger program that asks the customer to input his or her PIN on the ATM's numeric keypad. (PINs are seven-digit numbers. The program stores each digit in an element of an integer array.) The program also retrieves a copy of the customer's actual PIN from a database. (The PINs are also stored in the database as 7-element arrays.) If these two numbers match, then the customer's identity is validated. Your function is to compare the two arrays and determine whether they contain the same numbers.

Here are the specifications your function must meet:
Parameters The function is to accept as arguments two integer arrays of seven elements each. The first argument will contain the number entered by the customer. The second argument will contain the number retrieved from the bank's database.
Return value The function should return a Boolean true value, if the two arrays are identical. Otherwise, it should return false.
Here is the pseudocode for the function:
```

For each element in the first array
Compare the element with the element in the second array
that is in the corresponding position.
If the two elements contain different values
Return false.
End If.
End For.
Return true.

```

The C++ code is shown below.
```

bool testPIN(const int custPIN[], const int databasePIN[], int size)
{
for (int index = 0; index < size; index++)
{
if (custPIN[index] != databasePIN[index])
return false; // We've found two different values.
}
return true; // If we make it this far, the values are the same.
}

```

Because you have only been asked to write a function that performs the comparison between the customer's input and the PIN that was retrieved from the database, you will also need to design a driver. Program 7-23 shows the complete program.

\section*{Program 7-23}
```

// This program is a driver that tests a function comparing the
// contents of two int arrays.
\#include <iostream>
using namespace std;
// Function Prototype
bool testPIN(const int [], const int [], int);
int main ()
{
const int NUM_DIGITS = 7; // Number of digits in a PIN
int pin1[NUM_DIGITS] = {2, 4, 1, 8, 7, 9, 0}; // Base set of values.
int pin2[NUM_DIGITS] = {2, 4, 6, 8, 7, 9, 0}; // Only 1 element is
// different from pin1.
int pin3[NUM_DIGITS] = {1, 2, 3, 4, 5, 6, 7}; // All elements are
// different from pin1.
if (testPIN(pin1, pin2, NUM_DIGITS))
cout << "ERROR: pin1 and pin2 report to be the same.\n";
else
cout << "SUCCESS: pin1 and pin2 are different.\n";
if (testPIN(pin1, pin3, NUM_DIGITS))
cout << "ERROR: pin1 and pin3 report to be the same.\n";
else
cout << "SUCCESS: pin1 and pin3 are different.\n";
if (testPIN(pin1, pin1, NUM_DIGITS))
cout << "SUCCESS: pin1 and pin1 report to be the same.\n";
else
cout << "ERROR: pin1 and pin1 report to be different.\n";
return 0;
}

```
```

//*******************************************************************
// The following function accepts two int arrays. The arrays are
// compared. If they contain the same values, true is returned. *
// If they contain different values, false is returned. *
//********************************************************************
bool testPIN(const int custPIN[], const int databasePIN[], int size)
{
for (int index = 0; index < size; index++)
{
if (custPIN[index] != databasePIN[index])
return false; // We've found two different values.
}
return true; // If we make it this far, the values are the same.
}

```

\section*{Program Output}

SUCCESS: pin1 and pin2 are different.
SUCCESS: pin1 and pin3 are different.
SUCCESS: pin1 and pin1 report to be the same.

Case Study: See the Intersection of Sets Case Study on the Computer Science Portal at www. pearsonglobaleditions.com/gaddis.

\subsection*{7.11 Introduction to the STL vector}

CONCEPT: The Standard Template Library offers a vector data type, which in many ways, is superior to standard arrays.

The Standard Template Library (STL) is a collection of data types and algorithms that you may use in your programs. These data types and algorithms are programmer-defined. They are not part of the C++ language, but were created in addition to the built-in data types. If you plan to continue your studies in the field of computer science, you should become familiar with the STL. This section introduces one of the STL data types. For more information on the STL, see Chapter 17.
In this section, you will learn to use the vector data type. A vector is a container that can store data. It is like an array in the following ways:
- A vector holds a sequence of values or elements.
- A vector stores its elements in contiguous memory locations.
- You can use the array subscript operator [] to read the individual elements in the vector.

However, a vector offers several advantages over arrays. Here are just a few:
- You do not have to declare the number of elements that the vector will have.
- If you add a value to a vector that is already full, the vector will automatically increase its size to accommodate the new value.
- vectors can report the number of elements they contain.

\section*{Defining a vector}

To use vectors in your program, you must include the <vector> header file with the following statement:
```

\#include <vector>

```

NOTE: To use the vector data type, you should also have the using namespace std; statement in your program.

Now you are ready to define an actual vector object. The syntax for defining a vector is somewhat different from the syntax used in defining a regular variable or array. Here is an example:
```

vector<int> numbers;

```

This statement defines numbers as a vector of ints. Notice the data type is enclosed in angled brackets, immediately after the word vector. Because the vector expands in size as you add values to it, there is no need to declare a size. You can define a starting size, if you prefer. Here is an example:
```

vector<int> numbers(10);

```

This statement defines numbers as a vector of 10 ints. This is only a starting size, however. Although the vector has 10 elements, its size will expand if you add more than 10 values to it.

NOTE: If you specify a starting size for a vector, the size declarator is enclosed in parentheses, not in square brackets.

When you specify a starting size for a vector, you may also specify an initialization value. The initialization value is copied to each element. Here is an example:
```

vector<int> numbers(10, 2);

```

In this statement, numbers is defined as a vector of 10 ints . Each element in numbers is initialized to the value 2 .

You may also initialize a vector with the values in another vector. For example, look at the following statement. Assume set1 is a vector of ints that already has values stored in it.
```

vector<int> set2(set1);

```

After this statement executes, set2 will be a copy of set1.
Table 7-3 summarizes the vector definition procedures we have discussed.

Table 7-3 vector Definitions
\begin{tabular}{ll}
\hline Definition Format & Description \\
\hline vector<float> amounts; & Defines amounts as an empty vector of floats. \\
vector<string> names; & Defines names as an empty vector of string objects. \\
vector<int> scores \((15) ;\) & Defines scores as a vector of 15 ints. \\
vector<char> 1etters \((25, ~ ' A ') ;\) & \begin{tabular}{l} 
Defines letters as a vector of 25 characters. Each \\
element is initialized with 'A'.
\end{tabular} \\
vector<double> values2 (values1) ; & \begin{tabular}{l} 
Defines values2 as a vector of doubles. All the \\
elements of values1, which is also a vector of \\
doubles, are copied to value2.
\end{tabular} \\
\hline
\end{tabular}

\section*{Using an Initialization List with a vector in C++ 11}

If you are using \(C++11\), you can initialize a vector with a list of values, as shown in this example:
```

vector<int> numbers { 10, 20, 30, 40 };

```

This statement defines a vector of ints named numbers. The vector will have four elements, initialized with the values \(10,20,30\), and 40 . Notice the initialization list is enclosed in a set of braces, but you do not use an = operator before the list.

\section*{Storing and Retrieving Values in a vector}

To store a value in an element that already exists in a vector, you may use the array subscript operator []. For example, look at Program 7-24.

\section*{Program 7-24}
// This program stores, in two vectors, the hours worked by 5
// employees, and their hourly pay rates.
\#include <iostream>
\#include <iomanip>
\#include <vector>
using namespace std;
int main()
\{
const int NUM_EMPLOYEES = 5; // Number of employees
vector<int> hours(NUM_EMPLOYEES); // A vector of integers vector<double> payRate(NUM_EMPLOYEES); // A vector of doubles int index; // Loop counter
// Input the data.
cout << "Enter the hours worked by " << NUM_EMPLOYEES;
cout << " employees and their hourly rates. \(\mathrm{ln}^{\prime}\) ";
for (index \(=0\); index < NUM_EMPLOYEES; index++)
```

Program 7-24 (continued)
19 {
cout << "Hours worked by employee \#" << (index + 1);
cout << ": ";
cin >> hours[index];
cout << "Hourly pay rate for employee \#";
cout << (index + 1) << ": ";
cin >> payRate[index];
}
// Display each employee's gross pay.
cout << "\nHere is the gross pay for each employee:\n";
cout << fixed << showpoint << setprecision(2);
for (index = 0; index < NUM_EMPLOYEES; index++)
{
double grossPay = hours[index] * payRate[index];
cout << "Employee \#" << (index + 1);
cout << ": \$" << grossPay << endl;
}
return 0;
}

```

\section*{Program Output with Example Input Shown in Bold}

Enter the hours worked by 5 employees and their hourly rates.
Hours worked by employee \#1: 10 Enter
Hourly pay rate for employee \#1: 9.75 Enter
Hours worked by employee \#2: 15 Enter
Hourly pay rate for employee \#2: 8.62 Enter
Hours worked by employee \#3: 20 Enter
Hourly pay rate for employee \#3: 10.50 Enter
Hours worked by employee \#4: 40 Enter
Hourly pay rate for employee \#4: 18.75 Enter
Hours worked by employee \#5: 40 Enter
Hourly pay rate for employee \#5: 15.65 Enter
Here is the gross pay for each employee:
Employee \#1: \$97. 50
Employee \#2: \$129.30
Employee \#3: \$210.00
Employee \#4: \$750.00
Employee \#5: \$626.00

Notice Program 7-24 uses the following statements in lines 11 and 12 to define two vectors:
```

vector<int> hours(NUM_EMPLOYEES); // A vector of integers
vector<double> payRate(NUM_EMPLOYEES); // A vector of doubles

```

Both of the vectors are defined with the starting size 5 , which is the value of the named constant NUM_EMPLOYEES. The program uses the following loop in lines 18 through 26 to store a value in each element of both vectors:
```

for (index = 0; index < NUM_EMPLOYEES; index++)
{
cout << "Hours worked by employee \#" << (index + 1);
cout << ": ";
cin >> hours[index];
cout << "Hourly pay rate for employee \#";
cout << (index + 1) << ": ";
cin >> payRate[index];
}

```

Because the values entered by the user are being stored in vector elements that already exist, the program uses the array subscript operator [], as shown in the following statements, which appear in lines 22 and 25:
```

cin >> hours[index];
cin >> payRate[index];

```

\section*{Using the Range-Based for Loop with a vector in C++ 11}

With C++ 11, you can use a range-based for loop to step through the elements of a vector, as shown in Program 7-25.

\section*{Program 7-25}
```

// This program demonstrates the range-based for loop with a vector.
include <iostream>
\#include <vector>
using namespace std;
int main()
{
// Define and initialize a vector.
vector<int> numbers { 10, 20, 30, 40, 50 };
// Display the vector elements.
for (int val : numbers)
cout << val << endl;
return 0;
}

```

\section*{Program Output}

10
20
30
40
50

Program 7-26 shows how you can use a reference variable with the range-based for loop to store items in a vector.

\section*{Program 7-26}
```

// This program demonstrates the range-based for loop with a vector.
\#include <iostream>
\#include <vector>
using namespace std;
int main()
{
// Define a vector.
vector<int> numbers(5);
// Get values for the vector elements.
for (int \&val : numbers)
{
cout << "Enter an integer value: ";
cin >> val;
}
// Display the vector elements.
cout << "Here are the values you entered:\n";
for (int val : numbers)
cout << val << endl;
return 0;
}

```

\section*{Program Output with Example Input Shown in Bold}
```

Enter an integer value: 1 Enter
Enter an integer value: 2 Enter
Enter an integer value: 3 Enter
Enter an integer value: 4 Enter
Enter an integer value: 5 Enter
Here are the values you entered:
1
2
3
4
5

```

In line 9 , we define numbers as a vector of ints, with five elements. Notice in line 12 the range variable, va1, has an ampersand (\&) written in front of its name. This declares val as a reference variable. As the loop executes, the val variable will be an alias for a vector element. Any changes made to the val variable will actually be made to the vector element it references.

Also notice in line 20 we did not declare val as a reference variable (there is no ampersand written in front of the variable's name). Because the loop is simply displaying the vector elements, and does not need to change the vector's contents, there is no need to make val a reference variable.

\section*{Using the push_back Member Function}

You cannot use the [] operator to access a vector element that does not exist. To store a value in a vector that does not have a starting size, or that is already full, use the push_back member function. The push_back member function accepts a value as an argument and stores that value after the last element in the vector. (It pushes the value onto the back of the vector.) Here is an example:
```

numbers.push_back(25);

```

Assuming numbers is a vector of ints, this statement stores 25 as the last element. If numbers is full, the statement creates a new last element and stores 25 in it. If there are no elements in numbers, this statement creates an element and stores 25 in it.

Program 7-27 is a modification of Program 7-24. This version, however, allows the user to specify the number of employees. The two vectors, hours and payRate, are defined without starting sizes. Because these vectors have no starting elements, the push_back member function is used to store values in the vectors.

\section*{Program 7-27}
```

// This program stores, in two arrays, the hours worked by 5
// employees, and their hourly pay rates.
\#include <iostream>
\#include <iomanip>
\#include <vector>
using namespace std;
int main()
{
vector<int> hours; // hours is an empty vector
vector<double> payRate; // payRate is an empty vector
int numEmployees; // The number of employees
int index; // Loop counter
// Get the number of employees.
cout << "How many employees do you have? ";
cin >> numEmployees;
// Input the payroll data.
cout << "Enter the hours worked by " << numEmployees;
cout << " employees and their hourly rates.\n";
for (index = 0; index < numEmployees; index++)
{
int tempHours; // To hold the number of hours entered
double tempRate; // To hold the pay rate entered

```

\section*{Program 7-27 (continued)}
```

    cout << "Hours worked by employee #" << (index + 1);
    cout << ": ";
    cin >> tempHours;
    hours.push_back(tempHours); // Add an element to hours
    cout << "Hourly pay rate for employee #";
    cout << (index + 1) << ": ";
    cin >> tempRate;
    payRate.push_back(tempRate); // Add an element to payRate
    }
    // Display each employee's gross pay.
    cout << "Here is the gross pay for each employee:\n";
    cout << fixed << showpoint << setprecision(2);
    for (index = 0; index < numEmployees; index++)
    {
        double grossPay = hours[index] * payRate[index];
        cout << "Employee #" << (index + 1);
        cout << ": $" << grossPay << endl;
        }
        return 0;
    }

```

\section*{Program Output with Example Input Shown in Bold}

How many employees do you have? 3 Enter
Enter the hours worked by 3 employees and their hourly rates.
Hours worked by employee \#1: 40 Enter
Hourly pay rate for employee \#1: 12.63 Enter
Hours worked by employee \#2: 25 Enter
Hourly pay rate for employee \#2: 10.35 Enter
Hours worked by employee \#3: 45 Enter
Hourly pay rate for employee \#3: 22.65 Enter
Here is the gross pay for each employee:
Employee \#1: \$505. 20
Employee \#2: \$258.75
Employee \#3: \$1019.2

Notice in lines 40 through 45 , the second loop, which calculates and displays each employee's gross pay, uses the [] operator to access the elements of the hours and payRate vectors.
```

for (index = 0; index < numEmployees; index++)
{
double grossPay = hours[index] * payRate[index];
cout << "Employee \#" << (index + 1);
cout << ": \$" << grossPay << endl;
}

```

This is possible because the first loop in lines 22 through 35 uses the push_back member function to create the elements in the two vectors.

\section*{Determining the Size of a vector}

Unlike arrays, vectors can report the number of elements they contain. This is accomplished with the size member function. Here is an example of a statement that uses the size member function:
```

numValues = set.size();

```

In this statement, assume numValues is an int, and set is a vector. After the statement executes, numValues will contain the number of elements in set.

The size member function is especially useful when you are writing functions that accept vectors as arguments. For example, look at the following code for the showValues function:
```

void showValues(vector<int> vect)
{
for (int count = 0; count < vect.size(); count++)
cout << vect[count] << endl;
}

```

Because the vector can report its size, this function does not need to accept a second argument indicating the number of elements in the vector. Program 7-28 demonstrates this function.

\section*{Program 7-28}
```

// This program demonstrates the vector size
// member function.
\#include <iostream>
\#include <vector>
using namespace std;
// Function prototype
void showValues(vector<int>);
int main()
{
vector<int> values;
// Put a series of numbers in the vector.
for (int count = 0; count < 7; count++)
values.push_back(count * 2);
// Display the numbers.
showValues(values);
return 0;
}
|/**************************************************
// Definition of function showValues. *
// This function accepts an int vector as its *
// argument. The value of each of the vector's *
// elements is displayed. *
//***************************************************

```
(program continues)

\section*{Program 7-28 (continued)}
```

29
31 {
32
33
34

```
```

30 void showValues(vector<int> vect)

```
30 void showValues(vector<int> vect)
```

    for (int count = 0; count < vect.size(); count++)
    ```
    for (int count = 0; count < vect.size(); count++)
        cout << vect[count] << endl;
        cout << vect[count] << endl;
}
```

}

```

\section*{Program Output}

0
2
4
6
8
10
12

\section*{Removing Elements from a vector}

Use the pop_back member function to remove the last element from a vector. In the following statement, assume collection is the name of a vector:
```

collection.pop_back();

```

This statement removes the last element from the collection vector. Program 7-29 demonstrates the function.

\section*{Program 7-29}
```

// This program demonstrates the vector pop_back member function.
\#include <iostream>
\#include <vector>
using namespace std;
int main()
{
vector<int> values;
// Store values in the vector.
values.push_back(1);
values.push_back(2);
values.push_back(3);
cout << "The size of values is " << values.size() << endl;
// Remove a value from the vector.
cout << "Popping a value from the vector ... \n";
values.pop_back();
cout << "The size of values is now " << values.size() << endl;

```
```

21 // Now remove another value from the vector.
22 cout << "Popping a value from the vector ... \n";
23 values.pop_back();
24
25
26
27
28
29
30
return 0;
}

```

\section*{Program Output}

The size of values is 3
Popping a value from the vector...
The size of values is now 2
Popping a value from the vector...
The size of values is now 1
Popping a value from the vector...
The size of values is now 0

\section*{Clearing a vector}

To completely clear the contents of a vector, use the clear member function, as shown in the following statement:
```

numbers.clear();

```

After this statement executes, numbers will be cleared of all its elements. Program 7-30 demonstrates the function.

\section*{Program 7-30}
```

// This program demonstrates the vector clear member function.
\#include <iostream>
\#include <vector>
using namespace std;
int main()
{
vector<int> values(100);
cout << "The values vector has "
<< values.size() << " elements.\n";
cout << "I will call the clear member function ... \n";
values.clear();
cout << "Now, the values vector has "
<< values.size() << " elements.\n";
return 0;
}

```

\section*{Program 7-30 \\ (continued)}

\section*{Program Output}

The values vector has 100 elements. I will call the clear member function... Now, the values vector has 0 elements.

\section*{Detecting an Empty vector}

To determine if a vector is empty, use the empty member function. The function returns true if the vector is empty, and false if the vector has elements stored in it. Assuming numberVector is a vector, here is an example of its use:
```

if (numberVector.empty())
cout << "No values in numberVector.\n";

```

Program 7-31 uses a function named avgVector, which demonstrates the empty member function.

\section*{Program 7-31}
```

// This program demonstrates the vector's empty member function.
\#include <iostream>
\#include <vector>
using namespace std;
// Function prototype
double avgVector(vector<int>);
int main()
{
vector<int> values; // A vector to hold values
int numValues; // The number of values
double average; // To hold the average
// Get the number of values to average.
cout << "How many values do you wish to average? ";
cin >> numValues;
// Get the values and store them in the vector.
for (int count = 0; count < numValues; count++)
{
int tempValue;
cout << "Enter a value: ";
cin >> tempValue;
values.push_back(tempValue);
}
// Get the average of the values and display it.
average = avgVector(values);
cout << "Average: " << average << endl;

```
```

    return 0;
    }
/|****************************************************************
// Definition of function avgVector.
// This function accepts an int vector as its argument. If
// the vector contains values, the function returns the
// average of those values. Otherwise, an error message is
// displayed and the function returns 0.0.
|/*****************************************************************
double avgVector(vector<int> vect)
{
int total = 0; // accumulator
double avg; // average
if (vect.empty()) // Determine if the vector is empty
{
cout << "No values to average.\n";
avg = 0.0;
}
e1se
{
for (int count = 0; count < vect.size(); count++)
total += vect[count];
avg = total / vect.size();
}
return avg;
}

```

\section*{Program Output with Example Input Shown in Bold}

How many values do you wish to average? 5 Enter
Enter a value: 12
Enter a value: 18
Enter a value: 3
Enter a value: 7
Enter a value: 9
Average: 9
Program Output with Different Example Input Shown in Bold
How many values do you wish to average? O Enter
No values to average.
Average: 0

\section*{Summary of vector Member Functions}

Table 7-4 provides a summary of the vector member function we have discussed, as well as some additional ones.

Table 7-4 Some of the vector Member Functions
\begin{tabular}{|c|c|}
\hline Member Function & Description \\
\hline at (element) & \begin{tabular}{l}
Returns the value of the element located at element in the vector. \\
Example:
\[
x=\text { vect.at(5) ; }
\] \\
This statement assigns the value of the fifth element of vect to \(x\).
\end{tabular} \\
\hline clear () & \begin{tabular}{l}
Clears a vector of all its elements. \\
Example: \\
vect.clear() ; \\
This statement removes all the elements from vect.
\end{tabular} \\
\hline empty () & \begin{tabular}{l}
Returns true if the vector is empty. Otherwise, it returns false. \\
Example: \\
if (vect.empty()) \\
cout << "The vector is empty."; \\
This statement displays the message if vect is empty.
\end{tabular} \\
\hline pop_back() & \begin{tabular}{l}
Removes the last element from the vector. \\
Example: \\
vect.pop_back(); \\
This statement removes the last element of vect, thus reducing its size by 1 .
\end{tabular} \\
\hline push_back(value) & \begin{tabular}{l}
Stores value in the last element of the vector. If the vector is full or empty, a new element is created. \\
Example: \\
vect.push_back(7); \\
This statement stores 7 in the last element of vect.
\end{tabular} \\
\hline resize(elements, value) & \begin{tabular}{l}
Resizes a vector by elements elements. Each of the new elements is initialized with the value in value. \\
Example: \\
vect.resize(5, 1); \\
This statement increases the size of vect by five elements. The five new elements are initialized to the value 1.
\end{tabular} \\
\hline swap(vector2) & \begin{tabular}{l}
Swaps the contents of the vector with the contents of vector2. \\
Example: \\
vect1.swap (vect2); \\
This statement swaps the contents of vect1 and vect2.
\end{tabular} \\
\hline
\end{tabular}

\section*{Checkpoint}
7.27 What header file must you \#include in order to define vector objects?
7.28 Write a definition statement for a vector named frogs. frogs should be an empty vector of ints.
7.29 Write a definition statement for a vector named lizards. 1izards should be a vector of 20 floats.
7.30 Write a definition statement for a vector named toads. toads should be a vector of 100 chars, with each element initialized to ' \(Z\) '.
7.31 gators is an empty vector of ints. Write a statement that stores the value 27 in gators.
7.32 snakes is a vector of doubles, with 10 elements. Write a statement that stores the value 12.897 in element 4 of the snakes vector.

\section*{Review Questions and Exercises}

\section*{Short Answer}
1. What is the difference between a size declarator and a subscript?
2. Look at the following array definition:
int values[10];
How many elements does the array have?
What is the subscript of the first element in the array?
What is the subscript of the last element in the array?
Assuming that an int uses 4 bytes of memory, how much memory does the array use?
3. Why should a function that accepts an array as an argument, and processes that array, also accept an argument specifying the array's size?
4. Consider the following array definition:
int values[5] = \{ 4, 7, 6, 8, 2 \};
What does each of the following statements display?
cout << values[4] << endl;
cout \(\ll\) (values[2] + values[3]) \(\ll\) endl;
cout << ++values[1] << endl; \(\qquad\)
5. How can you declare an integer array of size 10 and initialize values of all elements to 0 ?
6. Look at the following array definition:
int numbers[5] = \{ 1, 2, 3 \};
What value is stored in numbers [2]?
What value is stored in numbers [4]?
7. Assuming that array1 and array2 are both arrays, why is it not possible to assign the contents of array2 to array1 with the following statement?
```

array1 = array2;

```
8. Assuming that numbers is an array of doubles, will the following statement display the contents of the array?
cout << numbers << endl;
9. Is an array passed to a function by value or by reference?
10. When you pass an array name as an argument to a function, what is actually being passed?
11. How do you establish a parallel relationship between two or more arrays?
12. Look at the following array definition:
double sales[8][10];
How many rows does the array have?
How many columns does the array have?
How many elements does the array have?
Write a statement that stores a number in the last column of the last row in the array.
13. When writing a function that accepts a two-dimensional array as an argument, which size declarator must you provide in the parameter for the array?
14. What advantages does a vector offer over an array?

\section*{Fill-in-the-Blank}
15. The \(\qquad\) indicates the number of elements, or values, an array can hold.
16. The size declarator must be \(a(n)\) \(\qquad\) with a value greater than \(\qquad\) .
17. The \(\qquad\) of an element in the array is denoted by its subscript.
18. The maximum subscript number of an array of size declarator N is \(\qquad\) .
19. The number inside the brackets of an array definition is the \(\qquad\) but the number inside an array's brackets in an assignment statement, or any other statement that works with the contents of the array, is the \(\qquad\) .
20. The size declarator of an array can be \(a(n)\) \(\qquad\) or a(n) \(\qquad\) but it can never be a variable.
21. The 5th element in an array somearray [] is stored in \(\qquad\) .
22. If an array is partially initialized, the uninitialized elements will be set to \(\qquad\) .
23. If the size declarator of an array definition is omitted, \(\mathrm{C}++\) counts the number of items in the \(\qquad\) to determine how large the array should be.
24. If an array is declared as int myarray[10], the memory size of the array will be
\(\qquad\) bytes.
25. You cannot use the \(\qquad\) operator to copy data from one array to another in a single statement.
26. Any time the name of an array is used without brackets and a subscript, it is seen as
\(\qquad\) -.
27. To pass an array to a function, pass the \(\qquad\) of the array.
28. \(\mathrm{A}(\mathrm{n})\) \(\qquad\) array is like several arrays of the same type put together.
29. It's best to think of a two-dimensional array as having \(\qquad\) and \(\qquad\) .
30. The number of size declarators in an n-dimensional array is \(\qquad\) .
31. When a two-dimensional array my2Darray [6] [5] is declared, it implies that the array has \(\qquad\) rows with \(\qquad\) elements in each.
32. When a two-dimensional array is passed to a function, the \(\qquad\) size must be specified.
33. The \(\qquad\) is a collection of programmer-defined data types and algorithms that you may use in your programs.
34. The two types of containers defined by the STL are \(\qquad\) and \(\qquad\) .
35. The vector data type is \(a(n)\) \(\qquad\) container.
36. To define a vector in your program, you must \#include the \(\qquad\) header file.
37. To store a value in a vector that does not have a starting size, or that is already full, use the \(\qquad\) member function.
38. To determine the number of elements in a vector, use the \(\qquad\) member function.
39. Use the \(\qquad\) member function to remove the last element from a vector.
40. To completely clear the contents of a vector, use the \(\qquad\) member function.

\section*{Algorithm Workbench}
41. Define a floating point array myvalues with 20 elements. Write a for loop that assigns the first 20 odd numbers to the array elements.
42. The numeric arrays NumArray1 and NumArray2 have 50 elements. Write a for loop to find SumArray where each element is the sum of the corresponding elements of the two arrays.
43. In a program, you need to store the identification numbers of ten employees (as ints) and their weekly gross pay (as doubles).
A) Define two arrays that may be used in parallel to store the ten employee identification numbers and gross pay amounts.
B) Write a loop that uses these arrays to print each employee's identification number and weekly gross pay.
44. Define a two-dimensional array of integers named Matrix, where both the number of rows and the number of columns are equal to 50 .
45. In a program, you need to store the populations of 12 countries.
A) Define two arrays that may be used in parallel to store the names of the countries and their populations.
B) Write a loop that uses these arrays to print each country's name and its population.
46. The following code totals the values in two arrays: numberArray1 and numberArray2. Both arrays have 25 elements. Will the code print the correct sum of values for both arrays? Why or why not?
```

int total = 0; // Accumulator
int count; // Loop counter
// Calculate and display the total of the first array.
for (count = 0; count < 24; count++)
total += numberArray1[count];
cout << "The total for numberArray1 is " << total << endl;
// Calculate and display the total of the second array.
for (count = 0; count < 24; count++)
tota1 += numberArray2[count];
cout << "The total for numberArray2 is " << total << endl;

```
47. Look at the following array definition:
int array[10][5];
Write a statement that assigns 100 to the last column of the first row of this array.
Write a for loop that assigns 10 to all the elements of the first column.
48. myMatrix is a two-dimensional array with 10 rows and 10 columns. Write code to find the sum of the elements of its main diagonal from top-left to bottom-right.
49. An application uses a two-dimensional array defined as follows:
int values[10][20];
Write code to find the minimum element of the first row.
Write code to find the maximum element of the last column.

\section*{True or False}
50. T F An array may contain elements with varied data types.
51. T F To calculate the amount of memory used by an array, multiply the number of elements by the number of bytes each element uses.
52. T F The individual elements of an array are accessed and indexed by unique numbers.
53. T F The subscript of an array may be a floating-point number.
54. T F If the value of a subscript or index is greater than the largest valid subscript of an array, the compiler will not report any error.
55. T F The elements in an array may be stored in non-contiguous locations in the main memory.
56. T F Arrays may have subscripts that have both positive and negative values.
57. T F You can write programs that use invalid subscripts for an array.
58. T F Arrays cannot be initialized when they are defined. A loop or other means must be used.
59. T F The values in an initialization list are stored in the array in the order they appear in the list.
60. T F A constant array must always have an initialization list.
61. T F If an array is partially initialized, it is possible to initialize the last few elements of the array without initializing the first portion.
62. T F If you leave an element uninitialized, you do not have to leave all the ones that follow it uninitialized.
63. T F If you leave out the size declarator of an array definition, you do not have to include an initialization list.
64. T F The uninitialized elements of a string array will automatically be set to the value " 0 ".
65. T F You cannot use the assignment operator to copy one array's contents to another in a single statement.
66. T F When an array name is used without brackets and a subscript, it is seen as the value of the first element in the array.
67. T F To pass an array to a function, pass the name of the array.
68. T F When defining a parameter variable to hold a single-dimensional array argument, you do not have to include the size declarator.
69. T F When an array is passed to a function, the function has access to the original array.
70. T F A two-dimensional array is like several identical arrays put together.
71. T F It's best to think of two-dimensional arrays as having rows and columns.
72. T F The first size declarator (in the declaration of a two-dimensional array) represents the number of columns. The second size definition represents the number of rows.
73. T F In a two-dimensional array defined as myarray [10] [20], the last element is accessed using the syntax myarray [9] [19].
74. T F C++ allows you to create arrays with three or more dimensions.
75. T F A vector is an associative container.
76. T F To use a vector, you must include the vector header file.
77. T F vectors can report the number of elements they contain.
78. T F You can use the [] operator to insert a value into a vector that has no elements.
79. T F If you add a value to a vector that is already full, the vector will automatically increase its size to accommodate the new value.

\section*{Find the Errors}

Each of the following definitions and program segments has errors. Locate as many as you can.
```

80. int size = 10;
double array[size];
81. int collection[-20];
82. int values[5];
for ( int i =1 ; i<=5 ; i++)
{
values[i] = 2 * i;
cout << "Values :" << values[i];
}
```
83. int array[4] \(=\{2.3,4.6,7.8,9.0,6.7\}\);
84. double series[] = \{ 2.3, "qwe", 2, '\$', 44.3\};
85. int array \([4][]=\{\{1,2\},\{3,4\},\{5,6\},\{7,8\}\}\);
86. char greeting[]=\{'H', 'e', '1', '1', 'o'\};
    cout << greeting;
87. int array1[4], array2[4] \(=\{3,6,9,12\}\);
    array1 = array2;
88. void showValues(int nums)
    \{
        for (int count = 0; count < 8; count++)
        cout << nums[count];
    \}
89. void showValues(int nums[4][])
    \{
    for (rows = 0; rows < 4; rows++)
        for (cols = 0; cols < 5; cols++)
            cout << nums[rows][cols];
    \}
90. vector<int> numbers \(=\{1,2,3,4\}\);

\section*{Programming Challenges}

\section*{1. Largest and Second Largest Even Numbers}

Write a program to input 15 integers into an array. The program should then display the largest and second largest even numbers in the array.

\section*{2. Rainfall Statistics}

Write a program that lets the user enter the total rainfall for each of 12 months into an array of doubles. The program should calculate and display the total rainfall for the year, the average monthly rainfall, and the months with the highest and lowest amounts. Input Validation: Do not accept negative numbers for monthly rainfall figures.

\section*{3. Chips and Salsa}

Write a program that lets a maker of chips and salsa keep track of sales for five different types of salsa: mild, medium, sweet, hot, and zesty. The program should use two parallel 5 -element arrays: an array of strings that holds the five salsa names, and an array of integers that holds the number of jars sold during the past month for each salsa type. The salsa names should be stored using an initialization list at the time the name array is created. The program should prompt the user to enter the number of jars sold for each type. Once this sales data has been entered, the program should produce a report that displays sales for each salsa type, total sales, and the names of the highest selling and lowest selling products.
Input Validation: Do not accept negative values for number of jars sold.

\section*{4. More Positives Than Negatives}

Write a function that accepts two arguments: an array of integers and its size. The function should return a Boolean indicating whether the array contains more positive numbers than negative numbers, not including zeros. Test the function in a program.

\section*{5. Conference Sessions}

An upcoming conference about C/C++ programming has three sessions planned:
- A session on the new features of \(\mathrm{C}++17\)
- A session on functional programming in \(\mathrm{C} / \mathrm{C}++\)
- A session on lambda functions

Attendees can subscribe for any session. The organizers want to keep track of which attendees are attending which session.
Write a program that stores this information in a two-dimensional array of Booleans, where each row represents an attendee and each column represents their subscription for a session. You can restrict the program to seven attendees, resulting in a \(7 \times 3\) array. The program should first have the user input the data for each attendee. Write two functions that take the array as their argument. One function should print out the number of people in each session and the other should return the number of people who subscribed to all sessions.

\section*{6. Temperature Variation}

The weather service center of a certain city records the highest temperature, lowest temperature, and humidity of each day. Write a program that maintains three arrays and initializes the highest temperature, lowest temperature, and humidity in the three arrays, for each day of the first 10 days of a month. The program should then create a weather report that includes the following information:
- Highest temperature and lowest temperature.
- Diurnal variation in each day.
- Humidity of each day and whether it is greater or less than the average humidity.

Finally, in an end note, it should display the maximum temperature, minimum temperature, and overall variation in temperature in the duration.

\section*{7. Union of Two Sets}

A set is a collection of similar elements. A union of two sets A and B is a set of elements in which each element belongs to set \(A\), set \(B\), or both. It is represented as \(A \cup B\). For example, if \(\mathrm{A}=\{1,3,5,7\}\) and \(\mathrm{B}=\{3,6,7,9,11\}\), then \(\mathrm{A} \cup \mathrm{B}=\{1,3,5,6,7,9,11\}\).

Write a program that represents set \(A\), set \(B\), and set \(A \cup B\) as three arrays. The maximum size of the arrays representing sets \(A\) and \(B\) should be 10 . The program should ask the user to input the sizes of sets A and B and then the elements of sets A and B . It should then display \(A \cup B\).

Input Validation: Do not accept values less than 1 or more than 10 as sizes of sets \(A\) and \(B\).

\section*{8. Lo Shu Magic Square}

The Lo Shu Magic Square is a grid with 3 rows and 3 columns shown in Figure 7-19. The Lo Shu Magic Square has the following properties:
- The grid contains the numbers 1 through 9 exactly.
- The sum of each row, each column, and each diagonal all add up to the same number. This is shown in Figure 7-20.
In a program, you can simulate a magic square using a two-dimensional array. Write a function that accepts a two-dimensional array as an argument, and determines whether the array is a Lo Shu Magic Square. Test the function in a program.

Figure 7-19 Lo Shu Magic Square
\begin{tabular}{|c|c|c|}
\hline 4 & 9 & 2 \\
\hline 3 & 5 & 7 \\
\hline 8 & 1 & 6 \\
\hline
\end{tabular}

Figure 7-20 Sums of the rows, columns, and diagonals

\section*{9. Price Calculation}

Write a program that uses the following arrays:
- plu: an array of price lookup codes (PLU) for products at a grocery store
- price: an array of gross prices of products
- vat: an array of the Value Added Tax (VAT) rate for each product

The program should relate the data in each array through the subscripts. The \(n\)th element of each array contains, respectively, the PLU, the gross price, and the VAT rate of the same product. For example, element 0 in the price array should contain the gross price of the product whose PLU code is stored in element 0 of the plu array. The same product's VAT rate should be stored in element 0 of the vat array. Write a function that takes three arguments-the array plu, the length of the array, and the PLU of a specific product-and returns the index of the PLU in the array. If the PLU cannot be found, the function must return -1 .
Write another function that takes six arguments: the three arrays, the length of these arrays (they have the same length), a PLU code, and the number of articles. The function should return the net total for this number of products, and -1 if the PLU code does not exist.

\section*{10. Driver's License Exam}

The local Driver's License Office has asked you to write a program that grades the written portion of the driver's license exam. The exam has 20 multiple-choice questions. Here are the correct answers:
1. A
6. B
11. A
16. C
2. D
7. A
12. C
17. C
3. B
8. B
13. D
18. A
4. B
9. C
14. B
19. D
5. C
10. D
15. D
20. B

Your program should store the correct answers shown above in an array. It should ask the user to enter the student's answers for each of the 20 questions, and the answers should be stored in another array. After the student's answers have been entered, the program should display a message indicating whether the student passed or failed the exam. (A student must correctly answer 15 of the 20 questions to pass the exam.) It should then display the total number of correctly answered questions, the total number of incorrectly answered questions, and a list showing the question numbers of the incorrectly answered questions.
Input Validation: Only accept the letters \(A, B, C\), or \(D\) as answers.

\section*{11. Exam Grader}

One of your professors has asked you to write a program to grade her final exams, which consist of only 20 multiple-choice questions. Each question has one of four possible answers: A, B, C, or D. The file CorrectAnswers.txt contains the correct answers for all of the questions, with each answer written on a separate line. The first line contains the answer to the first question, the second line contains the answer to the second question, and so forth. (Download the book's source code from the Computer Science Portal at www.pearsonglobaleditions.com/gaddis. You will find the file in the Chapter 07 folder.)
Write a program that reads the contents of the CorrectAnswers.txt file into a char array, then reads the contents of another file, containing a student's answers, into a second char array. (You can use the file StudentAnswers.txt for testing purposes. This
file is also in the Chapter 07 source code folder.) The program should determine the number of questions that the student missed, then display the following:
- A list of the questions missed by the student, showing the correct answer and the incorrect answer provided by the student for each missed question
- The total number of questions missed
- The percentage of questions answered correctly. This can be calculated as

Correctly Answered Questions \(\div\) Total Number of Questions
- If the percentage of correctly answered questions is 70 percent or greater, the program should indicate that the student passed the exam. Otherwise, it should indicate that the student failed the exam.

\section*{12. A Graded Social Network}

The goal of a social network is to connect people. In an early attempt, people were asked to grade each other on a scale of 1 to 10 . An algorithm would decide who was friend with whom. The idea was that anyone whom someone graded a 5 or more would be that person's friend.

In a certain experiment with three people, this was the input:
\begin{tabular}{clcl}
\hline Person & \begin{tabular}{l} 
Friend Score \\
of Person \(\mathbf{1}\)
\end{tabular} & \begin{tabular}{l} 
Friend Score \\
of Person 2
\end{tabular} & \begin{tabular}{l} 
Friend Score \\
of Person 3
\end{tabular} \\
\hline John & 10 & 4 & 7 \\
Mike & 3 & 2 & 4 \\
Mary & 10 & 10 & 10 \\
\hline
\end{tabular}

It was expected that people would be each other's friends, but it turned out that this was not the case. In this case, for example, Mike indicated that he had no friends at all. Because of this and various other obvious reasons, this social network failed. However, it may still be interesting to write a program to repeat the experiment. The program should use a string array of length 5 to hold the names of the people in the network, and five int arrays to hold their friend scores.
The program should let the user enter five names and five scores per person. It should then display the number of friends per person and their names.

\section*{13. Social Network Modification}

Modify the solution of Programming Challenge 12 such that two people can only be considered friends if each gives the other person a friend score of at least 5 .

\section*{14. Lottery Application}

Write a program that simulates a lottery. The program should have an array of five integers named lottery and should generate a random number in the range of 0 through 9 for each element in the array. The user should enter five digits, which should be stored in an integer array named user. The program is to compare the corresponding elements in the two arrays and keep a count of the digits that match. For example, the following shows the lottery array and the user array with sample numbers stored in each. There are two matching digits (elements 2 and 4).

\section*{Lottery array:}
\begin{tabular}{|l|l|l|l|l|}
\hline 7 & 4 & 9 & 1 & 3 \\
\hline
\end{tabular}

User array:
\begin{tabular}{|l|l|l|l|l|}
\hline 4 & 2 & 9 & 7 & 3 \\
\hline
\end{tabular}

The program should display the random numbers stored in the lottery array and the number of matching digits. If all of the digits match, display a message proclaiming the user as a grand prize winner.

\section*{15. vector Modification}

Modify the National Commerce Bank case study presented in Program 7-23 so pin1, pin2, and pin3 are vectors instead of arrays. You must also modify the testPIN function to accept a vector instead of an array.

\section*{16. World Series Champions}

If you have downloaded this book's source code, you will find the following files in this chapter's folder:
- Teams.txt-This file contains a list of several Major League baseball teams in alphabetical order. Each team listed in the file has won the World Series at least once.
- WorldSeriesWinners.txt-This file contains a chronological list of the World Series' winning teams from 1903 to 2012. (The first line in the file is the name of the team that won in 1903, and the last line is the name of the team that won in 2012. Note the World Series was not played in 1904 or 1994.)
Write a program that displays the contents of the Teams.txt file on the screen and prompts the user to enter the name of one of the teams. The program should then display the number of times that team has won the World Series in the time period from 1903 to 2012.

TIP: Read the contents of the WorldSeriesWinners.txt file into an array or vector. When the user enters the name of a team, the program should step through the array or vector counting the number of times the selected team appears.

\section*{17. Name Search}

If you have downloaded this book's source code, you will find the following files in this chapter's folder:
- GirlNames.txt—This file contains a list of the 200 most popular names given to girls born in the United States from 2000 to 2009.
- BoyNames.txt-This file contains a list of the 200 most popular names given to boys born in the United States from 2000 to 2009.
Write a program that reads the contents of the two files into two separate arrays or vectors. The user should be able to enter a boy's name, a girl's name, or both, and the application should display messages indicating whether the names were among the most popular.

\section*{18. Tic-Tac-Toe Game}

Write a program that allows two players to play a game of tic-tac-toe. Use a twodimensional char array with three rows and three columns as the game board. Each element of the array should be initialized with an asterisk (*). The program should run a loop that does the following:
- Displays the contents of the board array.
- Allows player 1 to select a location on the board for an X. The program should ask the user to enter the row and column numbers.
- Allows player 2 to select a location on the board for an O. The program should ask the user to enter the row and column numbers.
- Determines whether a player has won, or a tie has occurred. If a player has won, the program should declare that player the winner and end. If a tie has occurred, the program should display an appropriate message and end.
Player 1 wins when there are three Xs in a row on the game board. The Xs can appear in a row, in a column, or diagonally across the board. Player 2 wins when there are three Os in a row on the game board. The Os can appear in a row, in a column, or diagonally across the board. A tie occurs when all of the locations on the board are full, but there is no winner.

\section*{19. Hot or Cold Hints}

Write a program in which the user must guess a random number in the range from 1 to 100. The user must keep on guessing until the number is correctly guessed, but encouragements are printed to make sure that the user keeps on playing. In the student sample programs for this book, you will find a text file named 19_hints.txt. The file contains eight responses, such as "That is very cold. Try again.", "You are getting closer.", "I can feel the heat.", and so forth. The program should read the responses from the file into an array or vector. It should prompt the user to enter a value. If the value is correct, the program should end, but if the guess is not correct, it should be compared to the previous attempt. If this attempt is worse than the previous guess, one of the first four responses should be displayed. Otherwise, display one of the last four responses. For the first guess, the first four responses should be used when the difference between the guess and the correct answer is larger than 20.
```

Contents of 19_bints.txt:
Incorrect and very cold. You are not getting closer.
Oh my! You are far away and getting cold.
It's chilly in here. No number in the neighborhood.
It seems like winter is settling in. The secret is well hidden.
Not good yet, but you are getting closer and warmer.
Almost there, I can already feel the heat.
You are reaching the goal. It already feels comfy and warm.
Better than ever. The temperature is increasing.

```

\section*{20. 1994 Gas Prices}

In the student sample programs for this book, you will find a text file named 1994_ Weekly_Gas_Averages.txt. The file contains the average gas price for each week in the year 1994 (There are 52 lines in the file. Line 1 contains the average price for week 1 , line 2 contains the average price for week 2 , and so forth.) Write a program that reads the gas prices from the file into an array or a vector. The program should do the following:
- Display the lowest average price of the year, along with the week number for that price, and the name of the month in which it occurred.
- Display the highest average price of the year, along with the week number for that price, and the name of the month in which it occurred.
- Display the average gas price for each month. (To get the average price for a given month, calculate the average of the average weekly prices for that month.)

\section*{21. 2D Array Operations}

Write a program that creates a two-dimensional array initialized with test data. Use any data type you wish. The program should have the following functions:
- getTotal-This function should accept a two-dimensional array as its argument and return the total of all the values in the array.
- getAverage-This function should accept a two-dimensional array as its argument and return the average of all the values in the array.
- getRowTota1-This function should accept a two-dimensional array as its first argument and an integer as its second argument. The second argument should be the subscript of a row in the array. The function should return the total of the values in the specified row.
- getColumnTotal-This function should accept a two-dimensional array as its first argument and an integer as its second argument. The second argument should be the subscript of a column in the array. The function should return the total of the values in the specified column.
- getHighestInRow-This function should accept a two-dimensional array as its first argument and an integer as its second argument. The second argument should be the subscript of a row in the array. The function should return the highest value in the specified row of the array.
- getLowestInRow-This function should accept a two-dimensional array as its first argument and an integer as its second argument. The second argument should be the subscript of a row in the array. The function should return the lowest value in the specified row of the array.
Demonstrate each of the functions in this program.

\section*{Group Project}

\section*{22. Theater Seating}

This program should be designed and written by a team of students. Here are some suggestions:
- One student should design function main, which will call the other functions in the program. The remainder of the functions will be designed by other members of the team.
- The requirements of the program should be analyzed so that each student is given about the same workload.
- The parameters and return types of each function should be decided in advance.
- The program can be implemented as a multi-file program, or all the functions can be cut and pasted into the main file.
Here is the assignment: Write a program that can be used by a small theater to sell tickets for performances. The theater's auditorium has 15 rows of seats, with 30 seats in each row. The program should display a screen that shows which seats are available and which are taken. For example, the following screen shows a chart depicting each
seat in the theater. Seats that are taken are represented by an * symbol, and seats that are available are represented by a \# symbol.
\begin{tabular}{|c|c|}
\hline & Seats \\
\hline & 123456789012345678901234567890 \\
\hline Row 1 & ***\#\#\#***\#\#\#*\#\#\#\#\#\#\#\#*****\#\#\#\# \\
\hline Row 2 & \#\#\#\#*************\#\#\#\#*******\# \\
\hline Row 3 & **\#\#\#**********\#\#\#\#\#\#\#\#****\#\#\# \\
\hline Row 4 & **\#\#\#\#\#\#**************\#****** \\
\hline Row 5 & ******\#\#\#\#\#*********\#\#\#\#\#\#\#\# \\
\hline Row 6 & \#\#\#\#\#\#\#\#\#\#\#\#\#\#************\#\#\#\# \\
\hline Row 7 & \#\#\#\#\#\#\#* * * * * * * * * * \#\#\#\#\#\#\#\#\#\#\# \\
\hline Row 8 & ************\#****\#\#\#\#\#\#\#\#\#\#\#\# \\
\hline Row 9 & \#\#\#\#\#\#\#\#\#* * * * \#\#\#\#\#\#\#\#\#\#\#\#* * * \\
\hline Row 10 & \#\#\#\#\#**************\#\#\#\#\#\#\#\#\#\#\# \\
\hline Row 11 & \#**********\#\#\#\#\#\#\#\#\#\#\#\#\#\#\#\#\#* * \\
\hline Row 12 & \#\#\#\#\#\#\#\#\#\#\#\#\#********\#\#\#\#\#\#\#\#* \\
\hline Row 13 & \#\#\#* * * * * * * * * \#\#\#\#\#\#\#\#* * \#\#\#\#\#\# \\
\hline Row 14 & \#\#\#\#\#\#\#\#\#\#\#\#\#\#\#\#\#\#\#\#\#\#\#\#\#\#\#\#\#\# \\
\hline Row 15 & \#\#\#\#\#\#\#\#\#\#\#\#\#\#\#\#\#\#\#\#\#\#\#\#\#\#\#\#\#\# \\
\hline
\end{tabular}

Here is a list of tasks this program must perform:
- When the program begins, it should ask the user to enter the seat prices for each row. The prices can be stored in a separate array. (Alternatively, the prices may be read from a file.)
- Once the prices are entered, the program should display a seating chart similar to the one shown above. The user may enter the row and seat numbers for tickets being sold. Every time a ticket or group of tickets is purchased, the program should display the total ticket prices and update the seating chart.
- The program should keep a total of all ticket sales. The user should be given an option of viewing this amount.
- The program should also give the user an option to see a list of how many seats have been sold, how many seats are available in each row, and how many seats are available in the entire auditorium.
Input Validation: When tickets are being sold, do not accept row or seat numbers that do not exist. When someone requests a particular seat, the program should make sure that seat is available before it is sold.

8.4 Focus on Problem Solving and Program Design: A Case Study
8.5 Sorting and Searching vectors

\subsection*{8.1 Focus on Software Engineering: Introduction to Search Algorithms}

CONCEPT: A search algorithm is a method of locating a specific item in a larger collection of data. This section discusses two algorithms for searching the contents of an array.

It's very common for programs not only to store and process data stored in arrays, but also to search arrays for specific items. This section will show you two methods of searching an array: the linear search and the binary search. Each has its advantages and disadvantages.

\section*{The Linear Search}

The linear search is a very simple algorithm. Also known as the sequential search algorithm, it uses a loop to sequentially step through an array, starting with the first element. It compares each element with the value being searched for, and stops when either the value is found or the end of the array is encountered. If the value being searched for is not in the array, the algorithm will unsuccessfully search to the end of the array.

Here is the pseudocode for a function that performs the linear search:
```

Set found to false
Set position to -1
Set index to O

```
```

While found is false and index < number of elements
If list[index] is equal to search value
found = true
position = index
End If
Add 1 to index
End While
Return position

```

The 1 inearSearch function shown below is an example of \(\mathrm{C}++\) code used to perform a linear search on an integer array. The array arr, which has a maximum of size elements, is searched for an occurrence of the number stored in value. If the number is found, its array subscript is returned. Otherwise, -1 is returned, indicating the value did not appear in the array.
```

int linearSearch (const int arr[], int size, int value)
{
int index = 0; // Used as a subscript to search the array
int position = -1; // To record the position of the search value
bool found = false; // Flag to indicate if the value was found
while (index < size \&\& !found)
{
if (arr[index] == value) // If the value is found
{
found = true; // Set the flag
position = index; // Record the value's subscript
}
index++; // Go to the next element
}
return position; // Return the position, or -1
}

```

NOTE: The reason -1 is returned when the search value is not found in the array is because -1 is not a valid subscript.

Program 8-1 is a complete program that uses the 1 inearSearch function. It searches the five-element array tests to find a score of 100 .

\section*{Program 8-1}
```

// This program demonstrates the linear search algorithm.
\#include <iostream>
using namespace std;
// Function prototype
int linearSearch(const int[], int, int);
int main()
{
const int SIZE = 5;
int tests[SIZE] = { 87, 75, 98, 100, 82 };
int results;

```

13
    // Search the array for 100.
    results \(=1\) inearSearch(tests, SIZE, 100);
    // If linearSearch returned -1, then 100 was not found.
    if (results == -1)
    cout << "You did not earn 100 points on any test\n";
    else
    \{
        // Otherwise results contains the subscript of
        // the first 100 in the array.
        cout << "You earned 100 points on test ";
        cout \(\ll\) (results +1 ) << end1;
    \}
    return 0;
\}

// The linearSearch function performs a linear search on an
// integer array. The array arr, which has a maximum of size
// elements, is searched for the number stored in value. If the
// number is found, its array subscript is returned. Otherwise,
// -1 is returned indicating the value was not in the array.

int linearSearch(const int arr[], int size, int value)
\{
    int index \(=0 ; \quad / /\) Used as a subscript to search array
    int position \(=-1\); // To record position of search value
    bool found = false; // Flag to indicate if the value was found
    while (index < size \&\& !found)
    \{
        if (arr[index] == value) // If the value is found
        \{
            found \(=\) true; \(/ /\) Set the flag
            position \(=\) index; \(/ /\) Record the value's subscript
        \}
        index++; // Go to the next element
    \}
    return position; \(\quad / /\) Return the position, or -1

\section*{Program Output}

You earned 100 points on test 4

\section*{Inefficiency of the Linear Search}

The advantage of the linear search is its simplicity. It is very easy to understand and implement. Furthermore, it doesn't require the data in the array to be stored in any particular order. Its disadvantage, however, is its inefficiency. If the array being searched contains 20,000 elements, the algorithm will have to look at all 20,000 elements in order to find
a value stored in the last element (so the algorithm actually reads an element of the array 20,000 times).

In an average case, an item is just as likely to be found near the beginning of the array as near the end. Typically, for an array of N items, the linear search will locate an item in \(\mathrm{N} / 2\) attempts. If an array has 50,000 elements, the linear search will make a comparison with 25,000 of them in a typical case. This is assuming, of course, that the search item is consistently found in the array. ( \(\mathrm{N} / 2\) is the average number of comparisons. The maximum number of comparisons is always N .)
When the linear search fails to locate an item, it must make a comparison with every element in the array. As the number of failed search attempts increases, so does the average number of comparisons. Obviously, the linear search should not be used on large arrays if the speed is important.

\section*{The Binary Search}

The binary search is a clever algorithm that is much more efficient than the linear search. Its only requirement is that the values in the array be sorted in order. Instead of testing the array's first element, this algorithm starts with the element in the middle. If that element happens to contain the desired value, then the search is over. Otherwise, the value in the middle element is either greater than or less than the value being searched for. If it is greater, then the desired value (if it is in the list) will be found somewhere in the first half of the array. If it is less, then the desired value (again, if it is in the list) will be found somewhere in the last half of the array. In either case, half of the array's elements have been eliminated from further searching.

If the desired value wasn't found in the middle element, the procedure is repeated for the half of the array that potentially contains the value. For instance, if the last half of the array is to be searched, the algorithm immediately tests \(i t s\) middle element. If the desired value isn't found there, the search is narrowed to the quarter of the array that resides before or after that element. This process continues until either the value being searched for is found, or there are no more elements to test.

Here is the pseudocode for a function that performs a binary search on an array:
```

Set first to 0
Set last to the last subscript in the array
Set found to false
Set position to -1
While found is not true and first is less than or equal to last
Set middle to the subscript halfway between array[first]
and array[last]
If array[middle] equals the desired value
Set found to true
Set position to middle
Else If array[middle] is greater than the desired value
Set last to middle - 1
Else
Set first to middle + 1
End If
End While
Return position

```

This algorithm uses three index variables: first, last, and middle. The first and last variables mark the boundaries of the portion of the array currently being searched. They are initialized with the subscripts of the array's first and last elements. The subscript of the element halfway between first and last is calculated and stored in the middle variable. If the element in the middle of the array does not contain the search value, the first or last variables are adjusted so only the top or bottom half of the array is searched during the next iteration. This cuts the portion of the array being searched in half each time the loop fails to locate the search value.

The function binarySearch shown in the following example is used to perform a binary search on an integer array. The first parameter, array, which has a maximum of numElems elements, is searched for an occurrence of the number stored in value. If the number is found, its array subscript is returned. Otherwise, -1 is returned indicating the value did not appear in the array.
```

int binarySearch(const int array[], int numElems, int value)
{
int first = 0, // First array element
last = numElems - 1, // Last array element
middle, // Midpoint of search
position = -1; // Position of search value
bool found = false; // Flag
while (!found \&\& first <= last)
{
middle = (first + last) / 2; // Calculate midpoint
if (array[middle] == value) // If value is found at mid
{
found = true;
position = middle;
}
else if (array[middle] > value) // If value is in lower half
last = middle - 1;
else
first = middle + 1; // If value is in upper half
}
return position;
}

```

Program 8-2 is a complete program using the binarySearch function. It searches an array of employee ID numbers for a specific value.

\section*{Program 8-2}

\section*{Program Output with Example Input Shown in Bold}

Enter the employee ID you wish to search for: 199 Enter
That ID is found at element 4 in the array.

WARNING! Notice the array in Program 8-2 is initialized with its values already sorted in ascending order. The binary search algorithm will not work properly unless the values in the array are sorted.

\section*{The Efficiency of the Binary Search}

Obviously, the binary search is much more efficient than the linear search. Every time it makes a comparison and fails to find the desired item, it eliminates half of the remaining portion of the array that must be searched. For example, consider an array with 1,000 elements. If the binary search fails to find an item on the first attempt, the number of elements that remains to be searched is 500 . If the item is not found on the second attempt, the number of elements that remains to be searched is 250 . This process continues until the binary search has either located the desired item or determined that it is not in the array. With 1,000 elements, this takes no more than 10 comparisons. (Compare this to the linear search, which would make an average of 500 comparisons!)

Powers of 2 are used to calculate the maximum number of comparisons the binary search will make on an array of any size. (A power of 2 is 2 raised to the power of some number.) Simply find the smallest power of 2 that is greater than or equal to the number of elements in the array. For example, a maximum of 16 comparisons will be made on an array of 50,000 elements ( \(\left.2^{16}=65,536\right)\), and a maximum of 20 comparisons will be made on an array of \(1,000,000\) elements ( \(2^{20}=1,048,576\) ).

\subsection*{8.2 Focus on Problem Solving and Program Design: A Case Study}

The Demetris Leadership Center (DLC, Inc.) publishes the books, DVDs, and audio CDs listed in Table 8-1.

Table 8-1 Products
\begin{tabular}{llll}
\hline Product Title & Product Description & Product Number & Unit Price \\
\hline Six Steps to Leadership & Book & 914 & \(\$ 12.95\) \\
Six Steps to Leadership & Audio CD & 915 & \(\$ 14.95\) \\
The Road to Excellence & DVD & 916 & \(\$ 18.95\) \\
Seven Lessons of Quality & Book & 917 & \(\$ 16.95\) \\
Seven Lessons of Quality & Audio CD & 918 & \(\$ 21.95\) \\
Seven Lessons of Quality & DVD & 919 & \(\$ 31.95\) \\
Teams Are Made, Not Born & Book & 920 & \(\$ 14.95\) \\
Leadership for the Future & Book & 921 & \(\$ 14.95\) \\
Leadership for the Future & Audio CD & 922 & \(\$ 16.95\) \\
\hline
\end{tabular}

The manager of the Telemarketing Group has asked you to write a program that will help order-entry operators look up product prices. The program should prompt the user to enter a product number, and will then display the title, description, and price of the product.

\section*{Variables}

Table 8-2 lists the variables needed:

\section*{Table 8-2 Variables}
\begin{tabular}{ll}
\hline Variable & Description \\
\hline NUM_PRODS & \begin{tabular}{l} 
A constant integer initialized with the number of products the Demetris Leadership \\
Center sells. This value will be used in the definition of the program's array.
\end{tabular} \\
MIN_PRODNUM & A constant integer initialized with the lowest product number. \\
MAX_PRODNUM & A constant integer initialized with the highest product number. \\
id & Array of integers. Holds each product's number. \\
title & Array of strings, initialized with the titles of products. \\
\begin{tabular}{ll} 
description & Array of strings, initialized with the descriptions of each product. \\
prices & Array of doubles. Holds each product's price.
\end{tabular} \\
\hline
\end{tabular}

\section*{Modules}

The program will consist of the functions listed in Table 8-3.
Table 8-3 Functions
\begin{tabular}{ll}
\hline Function & Description \\
\hline main & \begin{tabular}{l} 
The program's main function. It calls the program's other functions. \\
getProdNum \\
Prompts the user to enter a product number. The function validates input \\
and rejects any value outside the range of correct product numbers.
\end{tabular} \\
binarySearch & \begin{tabular}{l} 
A standard binary search routine. Searches an array for a specified value. If the \\
value is found, its subscript is returned. If the value is not found, -1 is returned.
\end{tabular} \\
\hline
\end{tabular}

\section*{Function main}

Function main contains the variable definitions and calls the other functions. Here is its pseudocode:
```

do
Ca11 getProdNum
Cal7 binarySearch
If binarySearch returned -1
Inform the user that the product number was not found
else
Cal1 disp7ayProd
End If
Ask the user if the program should repeat
While the user wants to repeat the program

```

Here is its actual C++ code:
```

do
{
// Get the desired product number.
prodNum = getProdNum();
// Search for the product number.
index = binarySearch(id, NUM_PRODS, prodNum);
// Display the results of the search.
if (index == -1)
cout << "That product number was not found.\n";
else
displayProd(title, description, prices, index);
// Does the user want to do this again?
cout << "Would you like to look up another product? (y/n) ";
cin >> again;
} while (again == 'y' || again == 'Y');

```

The named constant NUM_PRODS is defined globally and initialized with the value 9. The arrays id, title, description, and prices will already be initialized with data.

\section*{The getProdNum Function}

The getProdNum function prompts the user to enter a product number. It tests the value to ensure it is in the range of \(914-922\) (which are the valid product numbers). If an invalid value is entered, it is rejected and the user is prompted again. When a valid product number is entered, the function returns it. The pseudocode is shown below.
```

Display a prompt to enter a product number
Read prodNum
While prodNum is invalid
Display an error message
Read prodNum
End While
Return prodNum

```

Here is the actual \(\mathrm{C}++\) code:
```

int getProdNum()
{
int prodNum;
cout << "Enter the item's product number: ";
cin >> prodNum;
// Validate input.
while (prodNum < MIN_PRODNUM || prodNum > MAX_PRODNUM)
{
cout << "Enter a number in the range of " << MIN_PRODNUM;
cout <<" through " << MAX_PRODNUM << ".\n";
cin >> prodNum;
}
return prodNum;
}

```

\section*{The binarySearch Function}

The binarySearch function is identical to the function discussed earlier in this chapter.

\section*{The displayProd Function}

The displayProd function has parameter variables named title, desc, price, and index. These accept as arguments (respectively) the title, description, and price arrays, and a subscript value. The function displays the data stored in each array at the subscript passed into index. Here is the \(\mathrm{C}++\) code:
```

void displayProd(const string title[], const string desc[],
const double price[], int index)
{
cout << "Title: " << title[index] << endl;
cout << "Description: " << desc[index] << endl;
cout << "Price: \$" << price[index] << endl;
}

```

\section*{The Entire Program}

Program 8-3 shows the entire program's source code.

\section*{Program 8-3}
```

// Demetris Leadership Center (DLC) product lookup program
// This program allows the user to enter a product number
// and then displays the title, description, and price of
// that product.
\#include <iostream>
\#include <string>
using namespace std;

```
```

const int NUM_PRODS = 9; // The number of products produced
const int MIN_PRODNUM = 914; // The lowest product number
const int MAX_PRODNUM = 922; // The highest product number
// Function prototypes
int getProdNum();
int binarySearch(const int [], int, int);
void displayProd(const string [], const string [], const double [], int);
int main()
{
// Array of product IDs
int id[NUM_PRODS] = {914, 915, 916, 917, 918, 919, 920,
921, 922};
// Array of product titles
string title[NUM_PRODS] =
{ "Six Steps to Leadership",
"Six Steps to Leadership",
"The Road to Excellence",
"Seven Lessons of Quality",
"Seven Lessons of Quality",
"Seven Lessons of Quality",
"Teams Are Made, Not Born",
"Leadership for the Future",
"Leadership for the Future"
};
// Array of product descriptions
string description[NUM_PRODS] =
{ "Book", "Audio CD", "DVD",
"Book", "Audio CD", "DVD",
"Book", "Book", "Audio CD"
};
// Array of product prices
double prices[NUM_PRODS] = {12.95, 14.95, 18.95, 16.95, 21.95,
31.95, 14.95, 14.95, 16.95};
int prodNum; // To hold a product number
int index; // To hold search results
char again; // To hold a Y or N answer
do
{
// Get the desired product number.
prodNum = getProdNum();
// Search for the product number.
index = binarySearch(id, NUM_PRODS, prodNum);
// Display the results of the search.
if (index == -1)

## Program 8-3

## (continued)

```
                    cout << "That product number was not found.\n";

Title: Teams Are Made, Not Born
Description: Book
Price: \$14.95
Would you like to look up another product? (y/n) n Enter

## Checkpoint

8.1 Describe the difference between the linear search and the binary search.
8.2 On average, with an array of 20,000 elements, how many comparisons will the linear search perform? (Assume the items being searched for are consistently found in the array.)
8.3 With an array of 20,000 elements, what is the maximum number of comparisons the binary search will perform?
8.4 If a linear search is performed on an array, and it is known that some items are searched for more frequently than others, how can the contents of the array be reordered to improve the average performance of the search?

### 8.3 Focus on Software Engineering: Introduction to Sorting Algorithms

CONCEPT: Sorting algorithms are used to arrange data into some order.

## Sorting Algorithms

Many programming tasks require the data in an array be sorted in some order. Customer lists, for instance, are commonly sorted in alphabetical order. Student grades might be sorted from highest to lowest, and product codes could be sorted so that all the products of the same color are stored together. To sort the data in an array, the programmer must use an appropriate sorting algorithm. A sorting algorithm is a technique for stepping through an array and rearranging its contents in some order.

The data in an array can be sorted in either ascending or descending order. If an array is sorted in ascending order, it means the values in the array are stored from lowest to highest. If the values are sorted in descending order, they are stored from highest to lowest. This section will introduce two simple sorting algorithms: the bubble sort and the selection sort.

## The Bubble Sort

The bubble sort is an easy way to arrange data in ascending or descending order. It is called the bubble sort algorithm because as it makes passes through and compares the elements of the array, certain values "bubble" toward the end of the array with each pass. For example, if you are using the algorithm to sort an array in ascending order, the larger values move toward the end. If you are using the algorithm to sort an array in descending order, the smaller values move toward the end. In this section, you will see how the bubble sort algorithm can be used to sort an array in ascending order.

Suppose we have the array shown in Figure 8-1. Let's see how the bubble sort can be used in arranging the array's elements in ascending order.

Figure 8-1 An array

| 7 | 2 | 3 | 8 | 9 | 1 |
| :---: | :---: | :---: | :---: | :---: | :---: |
| E1ement 0 Element 1 | Element 2 | E1ement 3 | Element 4 | Element 5 |  |

The bubble sort starts by comparing the first two elements in the array. If element 0 is greater than element 1, they are swapped. The array would then appear as shown in Figure 8-2.

Figure 8-2 Elements 0 and 1 are swapped

This method is repeated with elements 1 and 2 . If element 1 is greater than element 2 , they are swapped. The array would then appear as shown in Figure 8-3.

Figure 8-3 Elements 1 and 2 are swapped

Next, elements 2 and 3 are compared. In this array, these elements are already in the proper order (element 2 is less than element 3), so no values are swapped. As the cycle continues, elements 3 and 4 are compared. Once again, it is not necessary to swap the values because they are already in the proper order.

When elements 4 and 5 are compared, however, they must be swapped because element 4 is greater than element 5. The array now appears as shown in Figure 8-4.

Figure 8-4 Elements 4 and 5 are swapped

At this point, the entire array has been scanned once, and the largest value, 9 , is in the correct position. There are other elements, however, that are not yet in their final positions. So, the algorithm will make another pass through the array, comparing each element with its neighbor. In the next pass, it will stop comparing after reaching the next-to-last element because the last element already contains the correct value.

The second pass starts by comparing elements 0 and 1 . Because those two are in the proper order, they are not swapped. Elements 1 and 2 are compared next, but once again, they are not swapped. This continues until elements 3 and 4 are compared. Because element 3 is greater than element 4 , they are swapped. Element 4 is the last element that is compared during this pass, so this pass stops. The array now appears as shown in Figure 8-5.

Figure 8-5 Elements 3 and 4 are swapped

At the end of the second pass, the last two elements in the array contain the correct values. The third pass starts now, comparing each element with its neighbor. The third pass will not involve the last two elements, however, because they have already been sorted. When the third pass is finished, the last three elements will hold the correct values, as shown in Figure 8-6.

Figure 8-6 The array after the third pass

| 2 | 3 | 1 | 7 | 8 | 9 |
| :---: | :---: | :---: | :---: | :---: | :---: |
| E1ement 0 Element 1 | E1ement 2 | Element 3 | E1ement 4 | E1ement 5 |  |

Each time the algorithm makes a pass through the array, the portion of the array that is scanned is decreased in size by one element, and the largest value in the scanned portion of the array is moved to its final position. When all of the passes have been made, the array will appear as shown in Figure 8-7.

Figure 8-7 The array with all elements sorted

| 1 | 2 | 3 | 7 | 8 | 9 |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Element 0 Element 1 | Element 2 | Element 3 | Element 4 | Element 5 |  |

Here is the bubble sort algorithm in pseudocode:

```
For maxElement = each subscript in the array, from the last to the first
            For index = 0 To maxElement - 1
                If array[index] > array[index + 1]
                        swap array[index] with array[index + 1]
                End If
            End For
End For
```

And here is the C++ code for the bubble sort algorithm written as a function that sorts an array of integers. The function accepts two arguments: the array to sort, and the size of the array.

```
void bubbleSort(int array[], int size)
{
    int maxElement;
    int index;
    for (maxElement = size - 1; maxElement > 0; maxElement--)
    {
            for (index = 0; index < maxElement; index++)
```

\{

```
                if (array[index] > array[index + 1])
```

                \{
                swap(array[index], array[index + 1]);
                \}
            \}
    \}
    \}

In lines 3 and 4, the following local variables are defined:

- The maxElement variable will hold the subscript of the last element that is to be compared to its immediate neighbor.
- The index variable is used as an array subscript in one of the loops.

The function uses two for loops, one nested inside another. The outer loop begins in line 6 as follows:

```
for (maxElement = size - 1; maxElement > 0; maxElement--)
```

This loop will iterate once for each element in the array. It causes the maxElement variable to take on all of the array's subscripts, from the highest subscript down to 0 . After each iteration, maxElement is decremented by one.
The second loop, which is nested inside the first loop, begins in line 8 as follows:

```
for (index = 0; index < maxElement; index++)
```

This loop iterates once for each of the unsorted array elements. It starts index at 0 and increments it up through maxElement -1 . During each iteration, the comparison in line 10 is performed:

```
if (array[index] > array[index + 1])
```

This if statement compares the element at array [index] with its neighbor array [index +1 ]. If the element's neighbor is greater, the swap function is called in line 12 to swap the two elements.

## Swapping Array Elements

As you saw in the description of the bubble sort algorithm, certain elements are swapped as the algorithm steps through the array. Let's briefly discuss the process of swapping two items in computer memory. Assume we have the following variable declarations:

```
int a = 1;
int b = 9;
```

Suppose we want to swap the values in these variables so the variable a contains 9 , and the variable $b$ contains 1 . At first, you might think that we only need to assign the variables to each other, like this:

```
// ERROR! The following does NOT swap the variables.
a = b;
b = a;
```

To understand why this doesn't work, let's step through the two lines of code. The first statement

$$
a=b ;
$$

causes the value 9 to be assigned to a. But what happens to the value 1 that was previously stored in a? Remember, when you assign a new value to a variable, the new value replaces any value that was previously stored in the variable. So, the old value, 1 , will be thrown away.

Then, the next statement is

$$
b=a ;
$$

Because the variable a contains 9 , this assigns 9 to b. After these statements execute, the variables $a$ and $b$ will both contain the value 9 .

To successfully swap the contents of two variables, we need a third variable that can serve as a temporary storage location:

```
int temp;
```

Then, we can perform the following steps to swap the values in the variables $a$ and $b$ :

- Assign the value of a to temp.
- Assign the value of $b$ to $a$.
- Assign the value of temp to $b$.

Here is the code for a swap function that swaps two int arguments:

```
void swap(int &a, int &b)
{
    int temp = a;
    a = b;
    b = temp;
}
```

NOTE: It is critical that we use reference parameters in the swap function, because the function must be able to change the values of the items that are passed to it as arguments.

Program 8-4 demonstrates the bubbleSort function in a complete program.

## Program 8-4

```
// This program demonstrates the Bubble Sort algorithm.
#include <iostream>
using namespace std;
// Function prototypes
void bubbleSort(int[], int);
void swap(int &, int &);
int main()
{
        const int SIZE = 6;
        // Array of unsorted values
        int values[SIZE] = { 6, 1, 5, 2, 4, 3 };
```

```
    // Display the unsorted array.
    cout << "The unsorted values:\n";
    for (auto element : values)
        cout << element << " ";
    cout << endl;
    // Sort the array.
    bubbleSort(values, SIZE);
    // Display the sorted array.
    cout << "The sorted values:\n";
    for (auto element : values)
        cout << element << " ";
    cout << endl;
    return 0;
}
//***********************************************************************
// The bubbleSort function sorts an int array in ascending order.
//*******************************************************************
void bubbleSort(int array[], int size)
{
    int maxElement;
    int index;
    for (maxElement = size - 1; maxElement > 0; maxElement--)
    {
        for (index = 0; index < maxElement; index++)
        {
            if (array[index] > array[index + 1])
            {
                swap(array[index], array[index + 1]);
            }
        }
    }
}
//******************************************************
// The swap function swaps a and b in memory.
|/******************************************************
void swap(int &a, int &b)
{
    int temp = a;
    a = b;
    b = temp;
}
```

## Program Output

The unsorted values:
615243
The sorted values:
123456

## The Selection Sort Algorithm

The bubble sort algorithm is simple, but it is inefficient because values move by only one element at a time toward their final destination in the array. The selection sort algorithm usually performs fewer swaps because it moves items immediately to their final position in the array. The selection sort works like this: The smallest value in the array is located and moved to element 0 . Then, the next smallest value is located and moved to element 1 . This process continues until all of the elements have been placed in their proper order. Let's see how the selection sort works when arranging the elements of the array in Figure 8-8.

Figure 8-8 Values in an array

The selection sort scans the array, starting at element 0 , and locates the element with the smallest value. Then, the contents of this element are swapped with the contents of element 0 . In this example, the 1 stored in element 5 is swapped with the 5 stored in element 0 . After the swap, the array appears as shown in Figure 8-9.

Figure 8-9 Values in the array after the first swap

Then, the algorithm repeats the process, but because element 0 already contains the smallest value in the array, it can be left out of the procedure. This time, the algorithm begins the scan at element 1 . In this example, the value in element 2 is swapped with the value in element 1. Then, the array appears as shown in Figure 8-10.

Figure 8-10 Values in the array after the second swap

Once again the process is repeated, but this time the scan begins at element 2. The algorithm will find that element 5 contains the next smallest value. This element's value is swapped with that of element 2, causing the array to appear as shown in Figure 8-11.

Figure 8-11 Values in the array after the third swap

Next, the scanning begins at element 3 . Its value is swapped with that of element 5 , causing the array to appear as shown in Figure 8-12.

Figure 8-12 Values in the array after the fourth swap

At this point, there are only two elements left to sort. The algorithm finds that the value in element 5 is smaller than that of element 4 , so the two are swapped. This puts the array in its final arrangement, as shown in Figure 8-13.

Figure 8-13 Values in the array after the fifth swap

Here is the selection sort algorithm in pseudocode:

```
For start = each array subscript, from the first to the next-to-last
    minIndex = start
    minValue = array[start]
    For index = start + 1 To size - 1
            If array[index] < minValue
                minValue = array[index]
```

```
            minIndex = index
            End If
        End For
        swap array[minIndex] with array[start]
End For
```

The following C++ code implements the selection sort in a function. It accepts two arguments: an integer array, and the size of the array. The function uses the selection sort algorithm to arrange the values in the array in ascending order.

```
void selectionSort(int array[], int size)
{
    int minIndex, minValue;
    for (int start = 0; start < (size - 1); start++)
    {
        minIndex = start;
        minValue = array[start];
        for (int index = start + 1; index < size; index++)
        {
            if (array[index] < minValue)
            {
                minValue = array[index];
                    minIndex = index;
            }
        }
        swap(array[minIndex], array[start]);
    }
}
```

Inside the function are two for loops, one nested inside the other. The inner loop (in lines 9 through 16) sequences through the array, starting at array [start + 1], searching for the element with the smallest value. When the element is found, its subscript is stored in the variable minIndex, and its value is stored in minValue. The outer loop (lines 5 through 18) then exchanges the contents of this element with array [start] and increments start. This procedure repeats until the contents of every element have been moved to their proper location.

Program 8-5 demonstrates the selectionSort function in a complete program.

## Program 8-5

```
// This program demonstrates the Selection Sort algorithm.
#include <iostream>
using namespace std;
// Function prototypes
void selectionSort(int[], int);
void swap(int &, int &);
```

```
int main()
{
    const int SIZE = 6;
    // Array of unsorted values
    int values[SIZE] = { 6, 1, 5, 2, 4, 3 };
    // Display the unsorted array.
    cout << "The unsorted values:\n";
    for (auto element : values)
        cout << element << " ";
    cout << endl;
    // Sort the array.
    selectionSort(values, SIZE);
    // Display the sorted array.
    cout << "The sorted values:\n";
    for (auto element : values)
        cout << element << " ";
    cout << endl;
    return 0;
}
//***********************************************************************
// The selectionSort function sorts an int array in ascending order.
//************************************************************************
void selectionSort(int array[], int size)
{
        int minIndex, minValue;
        for (int start = 0; start < (size - 1); start++)
        {
            minIndex = start;
            minValue = array[start];
            for (int index = start + 1; index < size; index++)
            {
                if (array[index] < minValue)
                {
                    minValue = array[index];
                    minIndex = index;
                }
        }
        swap(array[minIndex], array[start]);
        }
}
//******************************************************
// The swap function swaps a and b in memory.
//****************************************************
void swap(int &a, int &b)
{
```

```
Program 8-5
62 int temp = a;
63 a = b;
64 b = temp
65 }
```

    (continued)
    
## Program Output

The unsorted values:
615243
The sorted values:
123456

### 8.4 Focus on Problem Solving and Program Design: A Case Study

Like the previous case study, this is a program developed for the Demetris Leadership Center. Recall that DLC, Inc., publishes books, DVDs, and audio CDs. (See Table 8-1 for a complete list of products, with title, description, product number, and price.) Table 8-4 shows the number of units of each product sold during the past six months.

## Table 8-4 Units Sold

| Product Number | Units Sold |
| :--- | :--- |
| 914 | 842 |
| 915 | 416 |
| 916 | 127 |
| 917 | 514 |
| 918 | 437 |
| 919 | 269 |
| 920 | 97 |
| 921 | 492 |
| 922 | 212 |

The vice president of sales has asked you to write a sales-reporting program that displays the following information:

- A list of the products in the order of their sales dollars (NOT units sold), from highest to lowest
- The total number of all units sold
- The total sales for the 6 -month period

## Variables

Table 8-5 lists the variables needed.

Table 8-5 Variables

| Variable | Description |
| :--- | :--- |
| NUM_PRODS | A constant integer initialized with the number of products that DLC, Inc., sells. |
|  | This value will be used in the definition of the program's array. |
| prodNum | Array of ints. Holds each product's number. |
| units | Array of ints. Holds each product's number of units sold. |
| prices | Array of doubles. Holds each product's price. |
| sales | Array of doubles. Holds the computed sales amounts (in dollars) of each product. |

The elements of the four arrays, prodNum, units, prices, and sales, will correspond with each other. For example, the product whose number is stored in prodNum [2] will have sold the number of units stored in units[2]. The sales amount for the product will be stored in sales[2].

## Modules

The program will consist of the functions listed in Table 8-6.
Table 8-6 Functions

| Function | Description |
| :--- | :--- |
| main | The program's main function. It calls the program's other functions. |
| calcSales | Calculates each product's sales. |
| dualSort | Sorts the sales array so the elements are ordered from highest to lowest. The <br> prodNum array is ordered so the product numbers correspond with the correct <br> sales figures in the sorted sales array. |
| swap | Swaps the values of two doubles that are passed by reference (overloaded). |
| swap | Swaps the values of two ints that are passed by reference (overloaded). <br> showOrder |
| Displays a list of the product numbers and sales amounts from the sorted <br> sales and prodNum arrays. |  |
| showTotals | Displays the total number of units sold and the total sales amount for the period. |

## Function main

Function main is very simple. It contains the variable definitions and calls the other functions. Here is the pseudocode for its executable statements:

```
Call calcSales
Call dualSort
Set display mode to fixed point with two decimal places of precision
Call showOrder
Call showTotals
```

Here is its actual C++ code:

```
// Calculate each product's sales.
calcSales(units, prices, sales, NUM_PRODS);
```

```
// Sort the elements in the sales array in descending
// order and shuffle the ID numbers in the id array to
// keep them in parallel.
dualSort(id, sales, NUM_PRODS);
// Set the numeric output formatting.
cout << setprecision(2) << fixed << showpoint;
// Display the products and sales amounts.
showOrder(sales, id, NUM_PRODS);
// Display total units sold and total sales.
showTotals(sales, units, NUM_PRODS);
```

The named constant NUM_PRODS will be defined globally and initialized to the value 9 .
The arrays id, units, and prices will already be initialized with data. (It will be left as an exercise for you to modify this program so the user may enter these values.)

## The calcSales Function

The calcSales function multiplies each product's units sold by its price. The resulting amount is stored in the sales array. Here is the function's pseudocode:

```
For index = each array subscript from O through the last subscript
    sales[index] = units[index] * prices[index]
End For
```

And here is the function's actual $\mathrm{C}++$ code:

```
void calcSales(const int units[], const double prices[],
    double sales[], int num)
{
    for (int index = 0; index < num; index++)
        sales[index] = units[index] * prices[index];
}
```

## The dua1Sort Function

The dualSort function is a modified version of the selection sort algorithm shown in Program 8-5. The dualSort function accepts two arrays as arguments: the sales array and the id array. The function actually performs the selection sort on the sales array. When the function moves an element in the sales array, however, it also moves the corresponding element in the id array. This is to ensure that the product numbers in the id array still have subscripts that match their sales figures in the sales array.

The dualSort function is also different in another way: It sorts the array in descending order. Here is the pseudocode for the dualSort function:

```
For start = each array subscript, from the first to the next-to-last
    index = start
    maxIndex = start
    tempId = id[start]
    maxValue = sales[start]
    For index = start + 1 To size - 1
```

```
            If sales[index] > maxValue
        maxValue = sales[index]
        tempId = id[index]
        maxIndex = index
        End If
    End For
    swap sales[maxIndex] with sales[start]
    swap id[maxIndex] with id[start]
End For
```

Here is the actual $\mathrm{C}++$ code for the dualSort function:

```
void dualSort(int id[], double sales[], int size)
{
    int start, maxIndex, tempid;
    double maxValue;
    for (start = 0; start < (size - 1); start++)
    {
        maxIndex = start;
        maxValue = sales[start];
        tempid = id[start];
        for (int index = start + 1; index < size; index++)
        {
            if (sales[index] > maxValue)
            {
            maxValue = sales[index];
            tempid = id[index];
            maxIndex = index;
            }
        }
        swap(sales[maxIndex], sales[start]);
        swap(id[maxIndex], id[start]);
    }
}
```

NOTE: Once the dualSort function is called, the id and sales arrays are no longer synchronized with the units and prices arrays. Because this program doesn't use units and prices together with id and sales after this point, it will not be noticed in the final output. However, it is never a good programming practice to sort parallel arrays in such a way that they are out of synchronization. It will be left as an exercise for you to modify the program so all the arrays are synchronized and used in the final output of the program.

## The Overloaded swap Functions

We have two overloaded versions of the swap function in this program: one that swaps double values, and another that swaps int values. We need two different versions of the swap function because the dualSort function swaps two elements of the sales array, which are doubles, then it swaps two elements of the id array, which are ints. Here is the $\mathrm{C}++$ code for both functions:

```
//********************************************************
// The swap function swaps doubles a and b in memory.
//********************************************************
void swap(double &a, double &b)
{
    double temp = a;
    a = b;
    b = temp;
}
//**********************************************************
// The swap function swaps ints a and b in memory.
//*************************
{
    int temp = a;
    a = b;
    b = temp;
}
```

## The showOrder Function

The showOrder function displays a heading and the sorted list of product numbers and their sales amounts. It accepts the id and sales arrays as arguments. Here is its pseudocode:

```
Display heading
For index = each subscript of the arrays from O through the last subscript
    Display id[index]
    Display sales[index]
End For
```

Here is the function's actual C++ code:

```
void showOrder(const double sales[], const int id[], int num)
{
    cout << "Product Number\tSales\n";
    cout << "---------------------------------\n";
    for (int index = 0; index < num; index++)
    {
        cout << id[index] << "\t\t$";
        cout << setw(8) << sales[index] << endl;
    }
    cout << endl;
}
```

## The showTota1s Function

The showTotals function displays the total number of units of all products sold and the total sales for the period. It accepts the units and sales arrays as arguments. Here is its pseudocode:

```
totalUnits = 0
totalSales = 0.0
```

```
For index = each array subscript from O through the last subscript
    Add units[index] to totalUnits[index]
    Add sales[index] to totalSales
End For
Display totalUnits with appropriate heading
Display totalSales with appropriate heading
```

Here is the function's actual C++ code:

```
void showTotals(const double sales[], const int units[], int num)
{
    int totalUnits = 0;
    double totalSales = 0.0;
    for (int index = 0; index < num; index++)
    {
        totalUnits += units[index];
        totalSales += sales[index];
    }
    cout << "Total Units Sold: " << totalUnits << endl;
    cout << "Total Sales: $" << totalSales << endl;
}
```

## The Entire Program

Program 8-6 shows the entire program's source code.

## Program 8-6

```
// This program produces a sales report for DLC, Inc.
#include <iostream>
#include <iomanip>
using namespace std;
// Function prototypes
void calcSales(const int[], const double[], double[], int);
void showOrder(const double[], const int[], int);
void dualSort(int[], double[], int);
void showTotals(const double[], const int[], int);
void swap(double&, double&);
void swap(int&, int&);
int main()
{
    // NUM_PRODS is the number of products produced.
    const int NUM_PRODS = 9;
    // Array with product ID numbers
    int id[NUM_PRODS] = { 914, 915, 916, 917, 918,
                                919, 920, 921, 922 };
    // Array with number of units sold for each product
    int units[NUM_PRODS] = { 842, 416, 127, 514, 437,
                                    269, 97, 492, 212 };
```

## Program 8-6 (continued)

26
// Array with product prices double prices[NUM_PRODS] $=\{12.95,14.95,18.95,16.95,21.95$, $31.95,14.95,14.95,16.95\} ;$
// Array to hold the computed sales amounts double sales[NUM_PRODS];
// Calculate each product's sales. calcSales(units, prices, sales, NUM_PRODS);
// Sort the elements in the sales array in descending
// order and shuffle the ID numbers in the id array to
// keep them in parallel.
dualSort(id, sales, NUM_PRODS);
// Set the numeric output formatting.
cout << setprecision(2) << fixed << showpoint;
// Display the products and sales amounts. showOrder(sales, id, NUM_PRODS);
// Display total units sold and total sales. showTotals(sales, units, NUM_PRODS); return 0;
\}

// Definition of calcSales. Accepts units, prices, and sales *
// arrays as arguments. The size of these arrays is passed *
// into the num parameter. This function calculates each
// product's sales by multiplying its units sold by each unit's *
// price. The result is stored in the sales array.

\subsection*{8.5 Sorting and Searching vectors (Continued from Section 7.11)}

CONCEPT: The sorting and searching algorithms you have studied in this chapter may be applied to STL vectors as well as arrays.

Once you have properly defined an STL vector and populated it with values, you may sort and search the vector with the algorithms presented in this chapter. Simply substitute the vector syntax for the array syntax when necessary. Program 8-7 demonstrates how to use the selection sort and binary search algorithms with a vector of strings.

\section*{Program 8-7}
```

// This program demonstrates how to sort and search a
// string vector using selection sort and binary search.
\#include <iostream>
\#include <string>
\#include <vector>
using namespace std;
// Function prototypes
void selectionSort(vector<string>\&);
void swap(string \&, string \&);
int binarySearch(const vector<string>\&, string);
int main()
{
string searchValue; // Value to search for
int position; /l Position of found value
// Define a vector of strings.
vector<string> names{ "Lopez", "Smith", "Pike", "Jones",
"Abernathy", "Ha11", "Wilson", "Kimura",
"Alvarado", "Harrison", "Geddes", "Irvine" };
// Sort the vector.
selectionSort(names);
// Display the vector's elements.
cout << "Here are the sorted names:\n";
for (auto element : names)
cout << element << endl;
cout << endl;
// Search for a name.
cout << "Enter a name to search for: ";
getline(cin, searchValue);
position = binarySearch(names, searchValue);

```

\section*{Review Questions and Exercises}

\section*{Short Answer}
1. Why is the linear search also called "sequential search"?
2. If a linear search function is searching for a value that is stored in the last element of a 10,000 -element array, how many elements will the search code have to read to locate the value?
3. In an average case involving an array of N elements, how many times will a linear search function have to read the array to locate a specific value?
4. A binary search function is searching for a value that is stored in the middle element of an array. How many times will the function read an element in the array before finding the value?
5. What is the maximum number of comparisons that a binary search function will make when searching for a value in a 1,000 -element array?
6. Why is the bubble sort inefficient for large arrays?
7. Why is the selection sort more efficient than the bubble sort on large arrays?

\section*{Fill-in-the-Blank}
8. The \(\qquad\) search algorithm steps sequentially through an array, comparing each item with the search value.
9. The \(\qquad\) search algorithm repeatedly divides the portion of an array being searched in half.
10. The average number of comparisons required in the linear search of N elements is
\(\qquad\) _.
11. The average number of comparisons required in the binary search of 16 elements is
\(\qquad\) .
12. If an array is sorted in \(\qquad\) order, the values are stored from lowest to highest.
13. If an array is sorted in \(\qquad\) order, the values are stored from highest to lowest.

\section*{True or False}
14. T F The bubble sort algorithm is very efficient in sorting a large list of elements because of the inherent simplicity of the algorithm.
15. T F A sorting algorithm always rearranges elements of a list in an ascending order.
16. T F Though the number of comparisons for both bubble sort and selection sort are the same, the number of exchanges is lesser for selection sort.
17. T The maximum number of comparisons performed by the linear search on an array of N elements is \(\mathrm{N} / 2\) (assuming the search values are consistently found).
18. Complete the following table calculating the average and maximum number of comparisons the linear search will perform, and the maximum number of comparisons the binary search will perform.
\begin{tabular}{|c|c|c|c|c|c|}
\hline Array Size \(\rightarrow\) & \begin{tabular}{l}

\end{tabular}

\section*{Programming Challenges}

\section*{1. Charge Account Validation}

Write a program that lets the user enter a charge account number. The program should determine if the number is valid by checking for it in the following list:
\begin{tabular}{llllll}
5658845 & 4520125 & 7895122 & 8777541 & 8451277 & 1302850 \\
8080152 & 4562555 & 5552012 & 5050552 & 7825877 & 1250255 \\
1005231 & 6545231 & 3852085 & 7576651 & 7881200 & 4581002
\end{tabular}

The list of numbers above should be initialized in a single-dimensional array. A simple linear search should be used to locate the number entered by the user. If the user enters a number that is in the array, the program should display a message saying the number is valid. If the user enters a number that is not in the array, the program should display a message indicating the number is invalid.

\section*{2. Overlapping Arrays}

An array overlaps another array if all elements of the latter array exist in the former array. They need not necessarily be in the same order. For example, [1,7,3,4,2] overlaps [ \(1,2,3\) ] because 1,2 , and 3 exist in [ \(1,7,3,4,2\) ]. To make the implementa-

Solving the Charge Account Validation Modification Problem
tion easy, \([1,7,3,4,2]\) overlaps \([1,1,2,3]\) as well. We don't need to check whether 1 appears twice in the first array.
Write a program that lets the user enter two arrays and displays whether the first array overlaps the second.
3. Overlapping Arrays Using Sort

Solve Programming Challenge 2 differently by sorting the larger array and performing a binary search in the sorted array.

\section*{4. Charge Account Validation Modification}

Modify the program you wrote for Problem 1 (Charge Account Validation) so it performs a binary search to locate valid account numbers. Use the selection sort algorithm to sort the array before the binary search is performed.

\section*{5. Rainfall Statistics Modification}

Modify the Rainfall Statistics program you wrote for Programming Challenge 2 of Chapter 7 (Rainfall Statistics). The program should display a list of months, sorted in order of rainfall, from highest to lowest.

\section*{6. String Selection Sort}

Modify the selectionSort function presented in this chapter so it sorts an array of strings instead of an array of ints. Test the function with a driver program. Use Program 8-8 as a skeleton to complete.

\section*{Program 8-8}
```

\#include <iostream>
\#include <string>
using namespace std;
int main()
{
const int NUM_NAMES = 20;
string names[NUM_NAMES] = {"Collins, Bill", "Smith, Bart", "Allen, Jim",
"Griffin, Jim", "Stamey, Marty", "Rose, Geri",
"Taylor, Terri", "Johnson, Jill",
"Allison, Jeff", "Looney, Joe", "Wolfe, Bill",
"James, Jean", "Weaver, Jim", "Pore, Bob",
"Rutherford, Greg", "Javens, Renee",
"Harrison, Rose", "Setzer, Cathy",
"Pike, Gordon", "Holland, Beth" };
// Insert your code to complete this program
return 0;
}

```

\section*{7. Binary String Search}

Modify the binarySearch function presented in this chapter so it searches an array of strings instead of an array of ints. Test the function with a driver program. Use

Program \(8-8\) as a skeleton to complete. (The array must be sorted before the binary search will work.)

\section*{8. Linear Search Algorithm}

Write a program that asks the user to input elements in an array of doubles of a maximum size of 50 . It should call a function that should use the linear search algorithm to do the following:
- Find a given value; display "Not Found" message if value is not found.
- Find the number of occurrences of the value.
- Display the location of each of the occurrences.

\section*{9. Overlapping Arrays Benchmarks}

In Programming Challenges 2 and 3, we wrote different solutions for the same problem. We do not know how exactly each solution performed. Write a program with two functions, one for each version of the Programming Challenge. Make sure that each function keeps a count of how many statements have been executed.
Then let the user input two sequences and print out how many statements each version of the solution needed to execute.

\section*{10. Insertion of Element in a Sorted Array}

Write a program to declare an array of size 15 initialized with 10 integers. Include a function show_array that can display the contents of the array. The program should then call a function sort_array to sort the array, and again call the show_array function to display the sorted array. It then calls a function insert_sorted that inserts an element in the appropriate position in the sorted array. Finally, the program calls show_array again to display the array after insertion of the value.
11. Using Files—String Selection Sort Modification

Modify the program you wrote for Programming Challenge 6 (String Selection Sort) so it reads in 20 strings from a file. The data can be found in the names.txt file.

\section*{12. Televoting}

In the student sample programs for this book, you will find text files named 12_artists.txt and \(12 \_\)votes.txt. The first file contains the names of 10 artists. The second file contains votes sent in by viewers for their favorite artist. Each line of the second file represents one vote, and contains only a number in the range from 1 to 10 to indicate which artist got that vote.
Write a program that reads both files-the names must be stored in an array and the votes in a vector-and displays the result. Write a function that accepts two arguments: a vector that contains the contents of the files and an array with scores that must be filled. The function should store the number of votes per artist in this array. Write a second function that sorts the scores in descending order and, at the same time, makes sure that the array with artists is sorted in a corresponding order. Finally, a third function should display the results in descending order mentioning both the score and the name of the artist.

9.9 Returning Pointers from Functions
9.10 Using Smart Pointers to Avoid Memory Leaks Program Design: A Case Study

\subsection*{9.1 Getting the Address of a Variable}

CONCEPT: The address operator (\&) returns the memory address of a variable.
Every variable is allocated a section of memory large enough to hold a value of the variable's data type. On a PC, for instance, it's common for 1 byte to be allocated for chars, 2 bytes for shorts, 4 bytes for ints, longs, and floats, and 8 bytes for doubles.

Each byte of memory has a unique address. A variable's address is the address of the first byte allocated to that variable. Suppose the following variables are defined in a program:
```

char letter;
short number;
float amount;

```

Figure 9-1 illustrates how they might be arranged in memory and shows their addresses.

Figure 9-1 Variables and their addresses

In Figure 9-1, the variable 1etter is shown at address 1200, number is at address 1201, and amount is at address 1203.

NOTE: The addresses of the variables shown in Figure 9-1 are arbitrary values used only for illustration purposes.

Getting the address of a variable is accomplished with an operator in C++. When the address operator ( \(\&\) ) is placed in front of a variable name, it returns the address of that variable. Here is an expression that returns the address of the variable amount:
\&amount
And here is a statement that displays the variable's address on the screen:
```

cout << \&amount;

```

NOTE: Do not confuse the address operator with the \& symbol used when defining a reference variable.

Program 9-1 demonstrates the use of the address operator to display the address, size, and contents of a variable.

\section*{Program 9-1}
```

// This program uses the \& operator to determine a variable's
// address and the sizeof operator to determine its size.
\#include <iostream>
using namespace std;
int main()
{
int x = 25;
cout << "The address of x is " << \&x << endl;
cout << "The size of x is " << sizeof(x) << " bytes\n";
cout << "The value in x is " << x << endl;
return 0;
}

```

\section*{Program Output}

The address of \(x\) is \(0 \times 8 f 05\)
The size of \(x\) is 4 bytes
The value in \(x\) is 25

NOTE: The address of the variable x is displayed in hexadecimal. This is the way addresses are normally shown in C++.

\subsection*{9.2 Pointer Variables}

CONCEPT: Pointer variables, which are often just called pointers, are designed to hold memory addresses. With pointer variables, you can indirectly manipulate data stored in other variables.

A pointer variable, which often is just called a pointer, is a special variable that holds a memory address. Just as int variables are designed to hold integers, and double variables are designed to hold floating-point numbers, pointer variables are designed to hold memory addresses.

Memory addresses identify specific locations in the computer's memory. Because a pointer variable holds a memory address, it can be used to hold the location of some other piece of data. This should give you a clue as to why it is called a pointer: It "points" to some piece of data that is stored in the computer's memory. Pointer variables also allow you to work with the data that they point to.
We've already used memory addresses in this book to work with data. Recall from Chapter 6 that when we pass an array as an argument to a function, we are actually passing the array's beginning address. For example, suppose we have an array named numbers, and we call the showValues function as shown here:
```

const int SIZE = 5;
int numbers[SIZE] = { 1, 2, 3, 4, 5 };
showValues(numbers, SIZE);

```

In this code, we are passing the name of the array, numbers, and its size as arguments to the showValues function. Here is the definition for the showValues function:
```

void showValues(int values[], int size)
{
for (int count = 0; count < size; count++)
cout << values[count] << endl;
}

```

In the function, the values parameter receives the address of the numbers array. It works like a pointer because it "points" to the numbers array, as shown in Figure 9-2.

Figure 9-2 Passing an array to a function

Inside the showValues function, anything done to the values parameter is actually done to the numbers array. We can say that the values parameter references the numbers array.

Also, recall from Chapter 6 that we discussed reference variables. A reference variable acts as an alias for another variable. It is called a reference variable because it references another variable in the program. Anything you do to the reference variable is actually done to the variable it references. For example, suppose we have the variable jellyDonuts, and we pass the variable to the getOrder function, as shown here:
```

int jellyDonuts;
getOrder(jel1yDonuts);

```

Here is the definition for the getOrder function:
```

void getOrder(int \&donuts)
{
cout << "How many doughnuts do you want? ";
cin >> donuts;
}

```

In the function, the donuts parameter is a reference variable, and it receives the address of the jellyDonuts variable. It works like a pointer because it "points" to the jellyDonuts variable as shown in Figure 9-3.

Inside the getOrder function, the donuts parameter references the jellyDonuts variable. Anything done to the donuts parameter is actually done to the jellyDonuts variable. When the user enters a value, the cin statement uses the donuts reference variable to indirectly store the value in the jellyDonuts variable.

Notice the connection between the donuts reference variable and the jellyDonuts argument is automatically established by C++ when the function is called. When you are writing this code, you don't have to go through the trouble of finding the memory address of the jellyDonuts variable then properly storing that address in the donuts reference variable.

Figure 9-3 Passing an argument by reference
```

je11yDonuts variable

```

```

    {
    cout << "How many doughnuts do you want? ";
    cin >> donuts;
    }

```

When you are storing a value in the donuts variable, you don't have to specify that the value should actually be stored in the jellyDonuts variable. C++ handles all of that automatically.

In C++, pointer variables are yet another mechanism for using memory addresses to work with pieces of data. Pointer variables are similar to reference variables, but pointer variables operate at a lower level. By this, I mean that C++ does not automatically do as much work for you with pointer variables as it does with reference variables. In order to make a pointer variable reference another item in memory, you have to write code that fetches the memory address of that item and assigns the address to the pointer variable. Also, when you use a pointer variable to store a value in the memory location that the pointer references, your code has to specify that the value should be stored in the location referenced by the pointer variable, and not in the pointer variable itself.

Because reference variables are easier to work with, you might be wondering why you would ever use pointers at all. In C++, pointers are useful, and even necessary, for many operations. One such operation is dynamic memory allocation. When you are writing a program that will need to work with an unknown amount of data, dynamic memory allocation allows you to create variables, arrays, and more complex data structures in memory while the program is running. We will discuss dynamic memory allocation in greater detail in this chapter. Pointers are also very useful in algorithms that manipulate arrays and work with certain types of strings. In object-oriented programming, which you will learn about in Chapters 13, 14, and 15, pointers are very useful for creating and working with objects, and for sharing access to those objects.

\section*{Creating and Using Pointer Variables}

The definition of a pointer variable looks pretty much like any other definition. Here is an example:
```

int *ptr;

```

The asterisk in front of the variable name indicates that \(p t r\) is a pointer variable. The int data type indicates that ptr can be used to hold the address of an integer variable. The definition statement above would read "ptr is a pointer to an int."

NOTE: In this definition, the word int does not mean ptr is an integer variable. It means ptr can hold the address of an integer variable. Remember, pointers only hold one kind of value: an address.

Some programmers prefer to define pointers with the asterisk next to the type name, rather than the variable name. For example, the previous definition shown above could be written as:
```

int* ptr;

```

This style of definition might visually reinforce the fact that ptr's data type is not int, but pointer-to-int. Both definition styles are correct.
It is never a good idea to define a pointer variable without initializing it with a valid memory address. If you inadvertently use an uninitialized pointer variable, you will be affecting some unknown location in memory. For that reason, it is a good idea to initialize pointer variables with the special value nullptr.
In C++ 11, the nullptr key word was introduced to represent the address 0 . So, assigning nullptr to a pointer variable makes the variable point to the address 0 . When a pointer is set to the address 0 , it is referred to as a null pointer because it points to "nothing." Here is an example of how you define a pointer variable and initialize it with the value nul1ptr:
```

int *ptr = nullptr;

```

NOTE: If you are using an older compiler that does not support the \(\mathrm{C}++11\) standard, you should initialize pointers with the integer 0 , or the value NULL. The value NULL is defined in the <iostream> header file (as well as other header files) to represent the value 0 .

Program 9-2 demonstrates a very simple usage of a pointer: storing and printing the address of another variable.

\section*{Program 9-2}
```

// This program stores the address of a variable in a pointer.
\#include <iostream>
using namespace std;
int main()
{
int x = 25; // int variable
int *ptr = nullptr; // Pointer variable, can point to an int
ptr = \&x; // Store the address of x in ptr
cout << "The value in x is " << x << endl;
cout << "The address of x is " << ptr << endl;
return 0;
}

```

\section*{Program Output}

The value in \(x\) is 25
The address of \(x\) is \(0 \times 7 e 00\)

In Program 9-2, two variables are defined: \(x\) and \(p t r\). The variable \(x\) is an int, and the variable \(p t r\) is a pointer to an int. The variable \(x\) is initialized with the value 25 , and \(p t r\) is initialized with nullptr. Then, the variable ptr is assigned the address of \(x\) with the following statement in line 10 :
```

ptr = \&x;

```

Figure 9-4 illustrates the relationship between \(p t r\) and \(x\).
Figure 9-4 ptr points to \(x\)

As shown in Figure 9-4, x, which is located at memory address \(0 \times 7 \mathrm{e} 00\), contains the number 25 . The ptr pointer contains the address \(0 x 7 \mathrm{e} 00\). In essence, it "points" to the variable x .

The real benefit of pointers is that they allow you to indirectly access and modify the variable being pointed to. In Program 9-2, for instance, ptr could be used to change the contents of the variable x . This is done with the indirection operator, which is an asterisk (*). When the indirection operator is placed in front of a pointer variable name, it dereferences the pointer. When you are working with a dereferenced pointer, you are actually working with the value the pointer is pointing to. This is demonstrated in Program 9-3.

\section*{Program 9-3}
```

// This program demonstrates the use of the indirection operator.
\#include <iostream>
using namespace std;
int main()
{
int x = 25; /l int variable
int *ptr = nullptr; // Pointer variable, can point to an int
ptr = \&x; // Store the address of x in ptr
// Use both x and ptr to display the value in x.
cout << "Here is the value in x, printed twice:\n";
cout << x << endl; // Displays the contents of x
cout << *ptr << endl; // Displays the contents of x
// Assign 100 to the location pointed to by ptr. This
// will actually assign 100 to x.
*ptr = 100;

```

\section*{Program 9-3}
        // Use both \(x\) and ptr to display the value in \(x\).
        cout << "Once again, here is the value in \(x: \backslash n " ;\)
        cout \(\ll x\) << endl; // Displays the contents of \(x\)
        cout << *ptr << endl; // Displays the contents of \(x\)
        return 0;
26 \}

\section*{Program Output}

Here is the value in \(x\), printed twice:
25
25
Once again, here is the value in \(x\) :
100
100

Take a closer look at the statement in line 10:
\[
\text { ptr }=\& x ;
\]

This statement assigns the address of the x variable to the ptr variable. Now look at line 15:
```

cout << *ptr << endl; // Displays the contents of x

```

When you apply the indirection operator (*) to a pointer variable, you are working not with the pointer variable itself, but with the item it points to. Because this statement sends the expression *ptr to the cout object, it does not display the value in \(p t r\), but the value that ptr points to. Since ptr points to the \(x\) variable, this statement displays the contents of the \(x\) variable.
Suppose the statement did not use the indirection operator. Suppose that statement had been written as:
```

cout << ptr << endl; // Displays an address

```

Because the indirection operator is not applied to ptr in this statement, it works directly with the ptr variable. This statement would display the address that is stored in ptr.
Now take a look at the following statement, which appears in line 19:
```

*ptr = 100;

```

Notice the indirection operator being used with ptr. That means the statement is not affecting ptr, but the item that ptr points to. This statement assigns 100 to the item \(p t r\) points to, which is the x variable. After this statement executes, 100 will be stored in the x variable.
Program 9-4 demonstrates that pointers can point to different variables.

\section*{Program 9-4}
```

// This program demonstrates a pointer variable referencing
// different variables.
\#include <iostream>
using namespace std;

```
```

int main()
{
int x = 25, y = 50, z = 75; // Three int variables
int *ptr = nullptr; // Pointer variable
// Display the contents of x, y, and z.
cout << "Here are the values of x, y, and z:\n";
cout << x << " " << y << " " << z << endl;
// Use the pointer to manipulate x, y, and z.
ptr = \&x; // Store the address of x in ptr.
*ptr += 100; /l Add 100 to the value in x.
ptr = \&y; // Store the address of y in ptr.
*ptr += 100; /l Add 100 to the value in y.
ptr = \&z; // Store the address of z in ptr.
*ptr += 100; // Add 100 to the value in z.
// Display the contents of x, y, and z.
cout << "Once again, here are the values of x, y, and z:\n";
cout << x << " " << y << " " << z << endl;
return 0;
}

```

\section*{Program Output}

Here are the values of \(x, y\), and \(z\) :
\(25 \quad 50 \quad 75\)
Once again, here are the values of \(x, y\), and \(z\) :
125150175

Take a closer look at the statement in line 17:
```

ptr = \&x;

```

This statement assigns the address of the \(x\) variable to the \(p t r\) variable. Now look at line 18:
*ptr += 100;
In this statement, notice the indirection operator (*) is used with the ptr variable. When we apply the indirection operator to \(p t r\), we are working not with \(p t r\), but with the item that \(p t r\) points to. When this statement executes, \(p t r\) is pointing at \(x\), so the statement in line 18 adds 100 to the contents of x . Then the following statement, in line 20, executes:
```

ptr = \&y;

```

This statement assigns the address of the \(y\) variable to the \(p t r\) variable. After this statement executes, ptr is no longer pointing at \(x\). Rather, it will be pointing at \(y\). The statement in line 21 , shown here, adds 100 to the \(y\) variable:
```

*ptr += 100;

```

These steps are repeated with the \(z\) variable in lines 23 and 24 .

NOTE: So far, you've seen three different uses of the asterisk in C++:
- As the multiplication operator, in statements such as
distance \(=\) speed * time;
- In the definition of a pointer variable, such as
int *ptr \(=\) nullptr;
- As the indirection operator, in statements such as
```

*ptr = 100;

```

\subsection*{9.3 The Relationship between Arrays and Pointers}

CONCEPT: Array names can be used as constant pointers, and pointers can be used as array names.

You learned in Chapter 7 that an array name, without brackets and a subscript, actually represents the starting address of the array. This means that an array name is really a pointer. Program 9-5 illustrates this by showing an array name being used with the indirection operator.

\section*{Program 9-5}
```

// This program shows an array name being dereferenced with the *
// operator.
\#include <iostream>
using namespace std;
int main()
{
short numbers[] = {10, 20, 30, 40, 50};
cout << "The first element of the array is ";
cout << *numbers << endl;
return 0;
}

```

\section*{Program Output}

The first element of the array is 10

Because numbers works like a pointer to the starting address of the array, the first element is retrieved when numbers is dereferenced. So how could the entire contents of an array be retrieved using the indirection operator? Remember, array elements are stored together in memory, as illustrated in Figure 9-5.

It makes sense that if numbers is the address of numbers [0], values could be added to numbers to get the addresses of the other elements in the array. It's important to know, however, that pointers do not work like regular variables when used in mathematical statements. In C++, when you add a value to a pointer, you are actually adding that value times

Figure 9-5 Array elements are stored in contiguous memory locations

the size of the data type being referenced by the pointer. In other words, if you add one to numbers, you are actually adding \(1^{*}\) sizeof(short) to numbers. If you add 2 to numbers, the result is numbers +2 * sizeof(short), and so forth. On a typical system, this means the following are true, because short integers typically use 2 bytes:
```

*(numbers + 1) is actually *(numbers + 1 * 2)
*(numbers + 2) is actually *(numbers + 2 * 2)
*(numbers + 3) is actually *(numbers + 3 * 2)

```
and so forth.
This automatic conversion means an element in an array can be retrieved by using its subscript, or by adding its subscript to a pointer to the array. If the expression *numbers, which is the same as * (numbers +0 ), retrieves the first element in the array, then * (numbers +1 ) retrieves the second element. Likewise, * (numbers +2 ) retrieves the third element, and so forth. Figure 9-6 shows the equivalence of subscript notation and pointer notation.

Figure 9-6 Subscript notation and pointer notation

NOTE: The parentheses are critical when adding values to pointers. The * operator has precedence over the + operator, so the expression *number +1 is not equivalent to * (number +1 ). *number +1 adds one to the contents of the first element of the array, while * (number +1 ) adds one to the address in number, then dereferences it.

Program 9-6 shows the entire contents of the array being accessed, using pointer notation.

\section*{Program 9-6}
// This program processes an array using pointer notation.
\#include <iostream>
3 using namespace std;
4
(program continues)
```

Program 9-6
(continued)

```
```

int main()

```
int main()
{
{
        const int SIZE = 5; // Size of the array
        const int SIZE = 5; // Size of the array
        int numbers[SIZE]; // Array of integers
        int numbers[SIZE]; // Array of integers
        int count; // Counter variable
        int count; // Counter variable
        // Get values to store in the array.
        // Get values to store in the array.
        // Use pointer notation instead of subscripts.
        // Use pointer notation instead of subscripts.
        cout << "Enter " << SIZE << " numbers: ";
        cout << "Enter " << SIZE << " numbers: ";
        for (count = 0; count < SIZE; count++)
        for (count = 0; count < SIZE; count++)
        cin >> *(numbers + count);
        cin >> *(numbers + count);
        // Display the values in the array.
        // Display the values in the array.
        // Use pointer notation instead of subscripts.
        // Use pointer notation instead of subscripts.
        cout << "Here are the numbers you entered:\n";
        cout << "Here are the numbers you entered:\n";
        for (count = 0; count < SIZE; count++)
        for (count = 0; count < SIZE; count++)
        cout << *(numbers + count)<< " ";
        cout << *(numbers + count)<< " ";
        cout << endl;
        cout << endl;
        return 0;
        return 0;
}
```

}

```

\section*{Program Output with Example Input Shown in Bold}
```

Enter 5 numbers: 5 1015 20 25 Enter

```
Here are the numbers you entered:
510152025

When working with arrays, remember the following rule:
array[index] is equivalent to *(array + index)

WARNING! Remember that \(\mathrm{C}++\) performs no bounds checking with arrays. When stepping through an array with a pointer, it's possible to give the pointer an address outside of the array.

To demonstrate just how close the relationship is between array names and pointers, look at Program 9-7. It defines an array of doubles and a double pointer, which is assigned the starting address of the array. Not only is pointer notation then used with the array name, but subscript notation is also used with the pointer!

\section*{Program 9-7}
```

// This program uses subscript notation with a pointer variable and
// pointer notation with an array name.
\#include <iostream>
using namespace std;
int main()

```
```

{
const int NUM_COINS = 5;
double coins[NUM_COINS] = {0.05, 0.1, 0.25, 0.5, 1.0};
double *doublePtr; // Pointer to a double
int count; // Array index
// Assign the address of the coins array to doublePtr.
doublePtr = coins;
// Display the contents of the coins array. Use subscripts
// with the pointer!
cout << "Here are the values in the coins array:\n";
for (count = 0; count < NUM_COINS; count++)
cout << doublePtr[count] << " ";
// Display the contents of the array again, but this time
// use pointer notation with the array name!
cout << "\nAnd here they are again:\n";
for (count = 0; count < NUM_COINS; count++)
cout << *(coins + count) << " ";
cout << endl;
return 0;
}

```

\section*{Program Output}

Here are the values in the coins array:
0.050 .10 .250 .51

And here they are again:
0.050 .10 .250 .51

Notice the address operator is not needed when an array's address is assigned to a pointer. Because the name of an array is already an address, use of the \& operator would be incorrect. You can, however, use the address operator to get the address of an individual element in an array. For instance, \&numbers [1] gets the address of numbers [1]. This technique is used in Program 9-8.

\section*{Program 9-8}
```

// This program uses the address of each element in the array.
\#include <iostream>
using namespace std;
int main()
{
const int NUM_COINS = 5;
double coins[NUM_COINS] = {0.05, 0.1, 0.25, 0.5, 1.0};
double *doublePtr = nullptr; // Pointer to a double
int count; // Array index

```

\section*{Program 9-8}
(continued)
```

12 // Use the pointer to display the values in the array.

```

```

23
24 }

```
```

    cout << "Here are the values in the coins array:\n";
    for (count = 0; count < NUM_COINS; count++)
    {
    // Get the address of an array element.
    doublePtr = &coins[count];
    // Display the contents of the element.
    cout << *doublePtr << " ";
    }
    cout << endl;
return 0;
}

```

\section*{Program Output}

Here are the values in the coins array:
0.050 .10 .250 .51

The only difference between array names and pointer variables is that you cannot change the address an array name points to. For example, consider the following definitions:
```

double readings[20], totals[20];
double *dptr = nullptr;

```

These statements are legal:
```

dptr = readings; // Make dptr point to readings.
dptr = totals; // Make dptr point to totals.

```

But these are illegal:
```

readings = totals; // ILLEGAL! Cannot change readings.
totals = dptr; // ILLEGAL! Cannot change totals.

```

Array names are pointer constants. You can't make them point to anything but the array they represent.

\subsection*{9.4 Pointer Arithmetic}

CONCEPT: Some mathematical operations may be performed on pointers.
The contents of pointer variables may be changed with mathematical statements that perform addition or subtraction. This is demonstrated in Program 9-9. The first loop increments the pointer variable, stepping it through each element of the array. The second loop decrements the pointer, stepping it backwards through the array.

\section*{Program 9-9}
```

// This program uses a pointer to display the contents of an array.
\#include <iostream>
using namespace std;
int main()
{
const int SIZE = 8;
int set[SIZE] = {5, 10, 15, 20, 25, 30, 35, 40};
int *numPtr = nullptr; // Pointer
int count; // Counter variable for loops
// Make numPtr point to the set array.
numPtr = set;
// Use the pointer to display the array contents.
cout << "The numbers in set are:\n";
for (count = 0; count < SIZE; count++)
{
cout << *numPtr << " ";
numPtr++;
}
// Display the array contents in reverse order.
cout << "\nThe numbers in set backward are:\n";
for (count = 0; count < SIZE; count++)
{
numPtr--;
cout << *numPtr << " ";
}
return 0;
}

```

\section*{Program Output}

The numbers in set are:
510152025303540
The numbers in set backward are:
\(\begin{array}{llllllll}40 & 35 & 30 & 25 & 20 & 15 & 10 & 5\end{array}\)

NOTE: Because numPtr is a pointer to an integer, the increment operator adds the size of one integer to numPtr, so it points to the next element in the array. Likewise, the decrement operator subtracts the size of one integer from the pointer.

Not all arithmetic operations may be performed on pointers. For example, you cannot multiply or divide a pointer. The following operations are allowable:
- The ++ and -- operators may be used to increment or decrement a pointer variable.
- An integer may be added to or subtracted from a pointer variable. This may be performed with the + and - operators, or the \(+=\) and \(-=\) operators.
- A pointer may be subtracted from another pointer.

\subsection*{9.5 Initializing Pointers}

CONCEPT: Pointers may be initialized with the address of an existing object.
Remember a pointer is designed to point to an object of a specific data type. When a pointer is initialized with an address, it must be the address of an object the pointer can point to. For instance, the following definition of pint is legal because myValue is an integer:
```

int myValue;
int *pint = \&myValue;

```

The following is also legal because ages is an array of integers:
```

int ages[20];
int *pint = ages;

```

But the following definition of pint is illegal because myFloat is not an int:
```

float myFloat;
int *pint = \&myFloat; // Illegal!

```

Pointers may be defined in the same statement as other variables of the same type. The following statement defines an integer variable, myValue, then defines a pointer, pint, which is initialized with the address of myValue:
```

int myValue, *pint = \&myValue;

```

And the following statement defines an array, readings, and a pointer, marker, which is initialized with the address of the first element in the array:
```

double readings[50], *marker = readings;

```

Of course, a pointer can only be initialized with the address of an object that has already been defined. The following is illegal, because pint is being initialized with the address of an object that does not exist yet:
```

int *pint = \&myValue; // Illegal!
int myValue;

```

\section*{Checkpoint}
9.1 Write a statement that displays the address of the variable count.
9.2 Write the definition statement for a variable f1tPtr. The variable should be a pointer to a float.
9.3 List three uses of the * symbol in C++.
9.4 What is the output of the following code?
```

int x = 50, y = 60, z = 70;
int *ptr = nullptr;
cout << x << " " << y << " " << z << endl;
ptr = \&x;

```
```

*ptr *= 10;
ptr = \&y;
*ptr *= 5;
ptr = \&z;
*ptr *= 2;
cout << x << " " << y << " " << z << endl;

```
9.5 Rewrite the following loop so it uses pointer notation (with the indirection operator) instead of subscript notation.
```

for (int x = 0; x < 100; x++)
cout << arr[x] << endl;

```
9.6 Assume ptr is a pointer to an int and holds the address 12000. On a system with 4-byte integers, what address will be in ptr after the following statement?
```

ptr += 10;

```
9.7 Assume pint is a pointer variable. Is each of the following statements valid or invalid? If any is invalid, why?
A) pint++;
B) --pint;
C) pint \(/=2\);
D) pint *= 4;
E) pint \(+=x\); // Assume \(x\) is an int.
9.8 Is each of the following definitions valid or invalid? If any is invalid, why?
A) int ivar; int *iptr = \&ivar;
B) int ivar, *iptr = \&ivar;
C) float fvar; int *iptr = \&fvar;
D) int nums[50], *iptr = nums;
E) int *iptr = \&ivar; int ivar;

\subsection*{9.6 Comparing Pointers}

CONCEPT: If one address comes before another address in memory, the first address is considered "less than" the second. C++'s relational operators may be used to compare pointer values.

Pointers may be compared by using any of C++'s relational operators:
```

>> < == != >= <=

```

In an array, all the elements are stored in consecutive memory locations, so the address of element 1 is greater than the address of element 0 . This is illustrated in Figure 9-7.

Figure 9-7 Array elements
An array of five integers
\begin{tabular}{|c|c|c|c|c|}
\hline \(\operatorname{arr}[0]\) & \(\operatorname{arr}[1]\) & \(\operatorname{arr}[2]\) & \(\operatorname{arr}[3]\) & \(\operatorname{arr}[4]\) \\
\hline \begin{tabular}{l}

\[
0 \times 5 \mathrm{~A} 00
\] \\
(Addresses)
\end{tabular} & \[
\uparrow_{0 \times 5 \mathrm{~A} 04}
\] & \[
\uparrow_{0 \times 5 \mathrm{~A} 08}
\] & \[
\overbrace{0 \times 5 \mathrm{AOC}}
\] & \[
\uparrow_{0 \times 5 \mathrm{~A} 10}
\] \\
\hline
\end{tabular}

Because the addresses grow larger for each subsequent element in the array, the expressions tested by the following if statements are all true:
```

if (\&arr[1] > \&arr[0])
if (arr < \&arr[4])
if (arr == \&arr[0])
if (\&arr[2] != \&arr[3])

```

NOTE: Comparing two pointers is not the same as comparing the values the two pointers point to. For example, the following if statement compares the addresses stored in the pointer variables ptr1 and ptr2:
```

if (ptr1 < ptr2)

```

The following statement, however, compares the values that ptr1 and ptr2 point to:
```

if (*ptr1 < *ptr2)

```

The capability of comparing addresses gives you another way to be sure a pointer does not go beyond the boundaries of an array. Program 9-10 initializes the pointer ptr with the starting address of the array numbers. The \(p t r\) pointer is then stepped through the numbers array until the address it contains is equal to the address of the last element of the array. Then, the pointer is stepped backward through the array until it points to the first element.

\section*{Program 9-10}
```

// This program uses a pointer to display the contents
// of an integer array.
\#include <iostream>
using namespace std;
int main()
{
const int SIZE = 8;
int numbers[SIZE] = {5, 10, 15, 20, 25, 30, 35, 40};
int *ptr = numbers; // Make ptr point to numbers
// Display the numbers in the array.
cout << "The numbers are:\n";
cout << *ptr << " "; // Display first element

```
```

    while (ptr < &numbers[SIZE - 1])
    {
        // Advance ptr to point to the next element.
        ptr++;
        // Display the value pointed to by ptr.
        cout << *ptr << " ";
    }
    // Display the numbers in reverse order.
    cout << "\nThe numbers backward are:\n";
    cout << *ptr << " "; // Display first element
    while (ptr > numbers)
    {
        // Move backward to the previous element.
        ptr--;
        // Display the value pointed to by ptr.
        cout << *ptr << " ";
    }
    return 0;
    }

```

\section*{Program Output}

The numbers are:
\(\begin{array}{llllllll}5 & 10 & 15 & 20 & 25 & 30 & 35 & 40\end{array}\)
The numbers backward are:
403530252015105

\subsection*{9.7 Pointers as Function Parameters}

CONCEPT: A pointer can be used as a function parameter. It gives the function access to the original argument, much like a reference parameter does.

In Chapter 6, you were introduced to the concept of reference variables being used as function parameters. A reference variable acts as an alias to the original variable used as an argument. This gives the function access to the original argument variable, allowing it to change the variable's contents. When a variable is passed into a reference parameter, the argument is said to be passed by reference.

Another way to pass an argument by reference is to use a pointer variable as the parameter. Admittedly, reference variables are much easier to work with than pointers. Reference variables hide all the "mechanics" of dereferencing and indirection. You should still learn to use pointers as function arguments, however, because some tasks (especially when you are dealing with strings) are best done with pointers.* Also, the C++ library has many functions that use pointers as parameters.

\footnotetext{
*It is also important to learn this technique in case you ever need to write a C program. In C , the only way to pass a variable by reference is to use a pointer.
}

Here is the definition of a function that uses a pointer parameter:
```

void doubleValue(int *val)
{
*va1 *= 2;
}

```

The purpose of this function is to double the variable pointed to by val with the following statement:
```

*va1 *= 2;

```

When val is dereferenced, the *= operator works on the variable pointed to by val. This statement multiplies the original variable, whose address is stored in va1, by 2 . Of course, when the function is called, the address of the variable that is to be doubled must be used as the argument, not the variable itself. Here is an example of a call to the doubleValue function:
```

doub7eValue(\&number);

```

This statement uses the address operator (\&) to pass the address of number into the val parameter. After the function executes, the contents of number will have been multiplied by 2. The use of this function is illustrated in Program 9-11.

\section*{Program 9-11}
```

// This program uses two functions that accept addresses of
// variables as arguments.
\#include <iostream>
using namespace std;
// Function prototypes
void getNumber(int *);
void doubleValue(int *);
int main()
{
int number;
// Call getNumber and pass the address of number.
getNumber(\&number);
// Call doubleValue and pass the address of number.
doubleValue(\&number);
// Display the value in number.
cout << "That value doubled is " << number << endl;
return 0;
}

```
```

||***********************************************************************
// Definition of getNumber. The parameter, input, is a pointer.
// This function asks the user for a number. The value entered
// is stored in the variable pointed to by input.
//******************************************************************
void getNumber(int *input)
{
cout << "Enter an integer number: ";
cin >> *input;
}
//*********************************************************************
// Definition of doubleValue. The parameter, val, is a pointer.
// This function multiplies the variable pointed to by val by
/l two.
/|********************************************************************
void doubleValue(int *val)
{
*va1 *= 2;
}

```

\section*{Program Output with Example Input Shown in Bold}

Enter an integer number: 10 Enter
That value doubled is 20

Program 9-11 has two functions that use pointers as parameters. Notice the function prototypes:
```

void getNumber(int *);
void doubleValue(int *);

```

Each one uses the notation int * to indicate the parameter is a pointer to an int. As with all other types of parameters, it isn't necessary to specify the name of the variable in the prototype. The * is required, though.

The getNumber function asks the user to enter an integer value. The following cin statement, in line 34 , stores the value entered by the user in memory:
```

cin >> *input;

```

The indirection operator causes the value entered by the user to be stored, not in input, but in the variable pointed to by input.

WARNING! It's critical that the indirection operator be used in the statement above. Without it, cin would store the value entered by the user in input, as if the value were an address. If this happens, input will no longer point to the number variable in function main. Subsequent use of the pointer will result in erroneous, if not disastrous, results.

When the getNumber function is called in line 15 , the address of the number variable in function main is passed as the argument. After the function executes, the value entered by the user is stored in number. Next, the doubleValue function is called in line 18, with the address of number passed as the argument. This causes number to be multiplied by 2 .

Pointer variables can also be used to accept array addresses as arguments. Either subscript or pointer notation may then be used to work with the contents of the array. This is demonstrated in Program 9-12.

\section*{Program 9-12}
// This program demonstrates that a pointer may be used as a
// parameter to accept the address of an array.
\#include <iostream>
\#include <iomanip>
using namespace std;
// Function prototypes
void getSales(double *, int);
double totalSales(double *, int);
```

int main()

```
\{
const int QTRS = 4;
double sales[QTRS];
// Get the sales data for all quarters.
getSales(sales, QTRS);
// Set the numeric output formatting.
cout << fixed << showpoint << setprecision(2);
// Display the total sales for the year.
cout << "The total sales for the year are \$";
cout << totalSales(sales, QTRS) << endl;
return 0;
\}
//*********************************************************************)
// Definition of getSales. This function uses a pointer to accept
// the address of an array of doubles. The function asks the user * // to enter sales figures and stores them in the array.
void getSales(double *arr, int size)
\{
        for (int count = 0; count < size; count++)
        \{
            cout << "Enter the sales figure for quarter ";
            cout << (count + 1) << ": ";
        cin >> arr[count];
    \}
\}
```

||********************************************************************
// Definition of totalSales. This function uses a pointer to *
// accept the address of an array. The function returns the total *
// of the elements in the array.
//******************************************************************
double totalSales(double *arr, int size)
{
double sum = 0.0;
for (int count = 0; count < size; count++)
{
sum += *arr;
arr++;
}
return sum;
}

```

\section*{Program Output with Example Input Shown in Bold}
```

Enter the sales figure for quarter 1: 10263.98 Enter
Enter the sales figure for quarter 2: 12369.69 Enter
Enter the sales figure for quarter 3: 11542.13 Enter
Enter the sales figure for quarter 4: 14792.06 Enter
The total sales for the year are \$48967.86

```

Notice in the getSales function in Program 9-12, even though the parameter arr is defined as a pointer, subscript notation is used in the cin statement in line 39:
```

cin >> arr[count];

```

In the totalSales function, arr is used with the indirection operator in line 54:
```

sum += *arr;

```

And in line 55 , the address in arr is incremented to point to the next element:
arr++;

NOTE: The two previous statements could be combined into the following statement:
```

sum += *arr++;

```

The * operator will first dereference arr, then the ++ operator will increment the address in arr.

\section*{Pointers to Constants}

You have seen how an item's address can be passed into a pointer parameter, and how the pointer can be used to modify the item that was passed as an argument. Sometimes it is necessary to pass the address of a const item into a pointer. When this is the case, the pointer must be defined as a pointer to a const item. For example, consider the following array definition:
```

const int SIZE = 6;
const double payRates[SIZE] = { 18.55, 17.45,
12.85, 14.97,
10.35, 18.89 };

```

In this code, payRates is an array of const doubles. This means each element in the array is a const double, and the compiler will not allow us to write code that changes the array's contents. If we want to pass the payRates array into a pointer parameter, the parameter must be declared as a pointer to const double. The following function shows such an example:
```

void displayPayRates(const double *rates, int size)
{
// Set numeric output formatting.
cout << setprecision(2) << fixed << showpoint;
// Display all the pay rates.
for (int count = 0; count < size; count++)
{
cout << "Pay rate for employee " << (count + 1)
<< " is \$" << *(rates + count) << endl;
}
}

```

In the function header, notice the rates parameter is defined as a pointer to const double. It should be noted the word const is applied to the thing that rates points to, not rates itself. This is illustrated in Figure 9-8.

Figure 9-8 rates is a pointer to const double

Because rates is a pointer to a const, the compiler will not allow us to write code that changes the thing that rates points to.

In passing the address of a constant into a pointer variable, the variable must be defined as a pointer to a constant. If the word const had been left out of the definition of the rates parameter, a compiler error would have resulted.

\section*{Passing a Nonconstant Argument into a Pointer to a Constant}

Although a constant's address can be passed only to a pointer to const, a pointer to const can also receive the address of a nonconstant item. For example, look at Program 9-13.

\section*{Program 9-13}
```

// This program demonstrates a pointer to const parameter
\#include <iostream>
using namespace std;
void displayValues(const int *, int);
int main()
{
// Array sizes
const int SIZE = 6;
// Define an array of const ints.
const int array1[SIZE] = { 1, 2, 3, 4, 5, 6 };
// Define an array of nonconst ints.
int array2[SIZE] = { 2, 4, 6, 8, 10, 12 };
// Display the contents of the const array.
displayValues(array1, SIZE);
// Display the contents of the nonconst array.
displayValues(array2, SIZE);
return 0;
}
//****************************************************
// The displayValues function uses a pointer to *
// parameter to display the contents of an array. *
//****************************************************
void displayValues(const int *numbers, int size)
{
// Display al1 the values.
for (int count = 0; count < size; count++)
{
cout << *(numbers + count) << " ";
}
cout << endl;
}

```

\section*{Program Output}

123456
24681012

NOTE: When you are writing a function that uses a pointer parameter, and the function is not intended to change the data the parameter points to, it is always a good idea to make the parameter a pointer to const. Not only will this protect you from writing code in the function that accidentally changes the argument, but the function will be able to accept the addresses of both constant and nonconstant arguments.

\section*{Constant Pointers}

In the previous section, we discussed pointers to const, that is, pointers that point to const data. You can also use the const key word to define a constant pointer. Here are the differences between a pointer to const and a const pointer:
- A pointer to const points to a constant item. The data that the pointer points to cannot change, but the pointer itself can change.
- With a const pointer, it is the pointer itself that is constant. Once the pointer is initialized with an address, it cannot point to anything else.

The following code shows an example of a const pointer:
```

int value = 22;
int * const ptr = \&value;

```

Notice in the definition of \(p t r\), the word const appears after the asterisk. This means that ptr is a const pointer. This is illustrated in Figure 9-9. In the code, ptr is initialized with the address of the value variable. Because ptr is a constant pointer, a compiler error will result if we write code that makes ptr point to anything else. An error will not result, however, if we use ptr to change the contents of value. This is because value is not constant, and ptr is not a pointer to const.

Figure 9-9 ptr is a const pointer to int

Constant pointers must be initialized with a starting value, as shown in the previous example code. If a constant pointer is used as a function parameter, the parameter will be initialized with the address that is passed as an argument into it, and cannot be changed to point to anything else while the function is executing. Here is an example that attempts to violate this rule:
```

void setToZero(int * const ptr)
{
ptr = 0; // ERROR!! Cannot change the contents of ptr.
}

```

This function's parameter, ptr, is a const pointer. It will not compile because we cannot have code in the function that changes the contents of ptr. However, ptr does not point to a const, so we can have code that changes the data that ptr points to. Here is an example of the function that will compile:
```

void setToZero(int * const ptr)
{
*ptr = 0;
}

```

Although the parameter is const pointer, we can call the function multiple times with different arguments. The following code will successfully pass the addresses of \(x, y\), and \(z\) to the setToZero function:
```

int x, y, z;
// Set x, y, and z to 0.
setToZero(\&x);
setToZero(\&y);
setToZero(\&z);

```

\section*{Constant Pointers to Constants}

So far, when using const with pointers, we've seen pointers to constants and we've seen constant pointers. You can also have constant pointers to constants. For example, look at the following code:
```

int value = 22;
const int * const ptr = \&value;

```

In this code, ptr is a const pointer to a const int. Notice the word const appears before int, indicating that ptr points to a const int, and it appears after the asterisk, indicating that \(p t r\) is a constant pointer. This is illustrated in Figure 9-10.

Figure 9-10 ptr is a const pointer to const int

In the code, ptr is initialized with the address of value. Because ptr is a const pointer, we cannot write code that makes ptr point to anything else. Because ptr is a pointer to const, we cannot use it to change the contents of value. The following code shows one more example of a const pointer to a const. This is another version of the displayValues function in Program 9-13.
```

void displayValues(const int * const numbers, int size)
{
// Display all the values.
for (int count = 0; count < size; count++)
{
cout << *(numbers + count) << " ";
}
cout << end1;
}

```

In this code, the parameter numbers is a const pointer to a const int. Although we can call the function with different arguments, the function itself cannot change what numbers points to, and it cannot use numbers to change the contents of an argument.

\subsection*{9.8 Dynamic Memory Allocation}

CONCEPT: Variables may be created and destroyed while a program is running.
As long as you know how many variables you will need during the execution of a program, you can define those variables up front. For example, a program to calculate the area of a rectangle will need three variables: one for the rectangle's length, one for the rectangle's width, and one to hold the area. If you are writing a program to compute the payroll for 30 employees, you'll probably create an array of 30 elements to hold the amount of pay for each person.

But what about those times when you don't know how many variables you need? For instance, suppose you want to write a test-averaging program that will average any number of tests. Obviously the program would be very versatile, but how do you store the individual test scores in memory if you don't know how many variables to define? Quite simply, you allow the program to create its own variables "on the fly." This is called dynamic memory allocation, and is only possible through the use of pointers.

To dynamically allocate memory means that a program, while running, asks the computer to set aside a chunk of unused memory large enough to hold a variable of a specific data type. Let's say a program needs to create an integer variable. It will make a request to the computer that it allocate enough bytes to store an int. When the computer fills this request, it finds and sets aside a chunk of unused memory large enough for the variable. It then gives the program the starting address of the chunk of memory. The program can access the newly allocated memory only through its address, so a pointer is required to use those bytes.

The way a C++ program requests dynamically allocated memory is through the new operator. Assume a program has a pointer to an int defined as
```

int *iptr = nullptr;

```

Here is an example of how this pointer may be used with the new operator:
```

iptr = new int;

```

This statement is requesting that the computer allocate enough memory for a new int variable. The operand of the new operator is the data type of the variable being created. Once the statement executes, iptr will contain the address of the newly allocated memory. This is illustrated in Figure 9-11. A value may be stored in this new variable by dereferencing the pointer:
```

*iptr = 25;

```

Any other operation may be performed on the new variable by simply using the dereferenced pointer. Here are some example statements:
```

cout << *iptr; // Display the contents of the new variable.
cin >> *iptr; // Let the user input a value.
total += *iptr; // Use the new variable in a computation.

```

Figure 9-11 iptr points to a chunk of dynamically allocated memory

Dynamically Allocating an Array

Although the statements above illustrate the use of the new operator, there's little purpose in dynamically allocating a single variable. A more practical use of the new operator is to dynamically create an array. Here is an example of how a 100 -element array of integers may be allocated:
```

iptr = new int[100];

```

Once the array is created, the pointer may be used with subscript notation to access it. For instance, the following loop could be used to store the value 1 in each element:
```

for (int count = 0; count < 100; count++)
iptr[count] = 1;

```

But what if there isn't enough free memory to accommodate the request? What if the program asks for a chunk large enough to hold a 100,000-element array of floats, and that much memory isn't available? When memory cannot be dynamically allocated, C++ throws an exception and terminates the program. Throwing an exception means the program signals that an error has occurred. You will learn more about exceptions in Chapter 16.

When a program is finished using a dynamically allocated chunk of memory, it should release it for future use. The delete operator is used to free memory that was allocated with new. Here is an example of how delete is used to free a single variable, pointed to by iptr:
```

delete iptr;

```

If iptr points to a dynamically allocated array, the [] symbol must be placed between delete and iptr:
```

delete [] iptr;

```

Failure to release dynamically allocated memory can cause a program to have a memory leak. For example, suppose the following grabMemory function is in a program:
```

void grabMemory()
{
const int SIZE = 100;
// Allocate space for a 100-element
/l array of integers.
int *iptr = new int[SIZE];
// The function ends without deleting the memory!
}

```

Notice the function dynamically allocates a 100-element int array and assigns its address to the iptr pointer variable. But then, the function ends without deleting the memory. Once the function has ended, the iptr pointer variable no longer exists. As a result, the program does not have a pointer to the dynamically allocated memory; therefore, the memory cannot be accessed or deleted. It will sit unused as long as the program is running.

WARNING! Only use pointers with delete that were previously used with new. If you use a pointer with delete that does not reference dynamically allocated memory, unexpected problems could result!

Program 9-14 demonstrates the use of new and delete. It asks for sales amounts for any number of days. The amounts are stored in a dynamically allocated array, then totaled and averaged.

\section*{Program 9-14}
```

// This program totals and averages the sales amounts for any
// number of days. The amounts are stored in a dynamically
// allocated array.
\#include <iostream>
\#include <iomanip>
using namespace std;
int main()
{
double *sales = nullptr, // To dynamically allocate an array
total = 0.0, // Accumulator
average; // To hold average sales
int numDays, // To hold the number of days of sales
count; // Counter variable
// Get the number of days of sales.
cout << "How many days of sales amounts do you wish ";
cout << "to process? ";
cin >> numDays;

```
```

20
21 // Dynamically allocate an array large enough to hold
22
23
24
25
26
27
28
29
30
31
32
33
34

4 2
4 3
4 4
4 5
4 6
4 7
4 8
4 9
5 0
51 return 0
52 }

```

\section*{Program Output with Example Input Shown in Bold}

How many days of sales amounts do you wish to process? 5 Enter Enter the sales amounts below.

Day 1: 898.63 Enter
Day 2: 652.32 Enter
Day 3: 741.85 Enter
Day 4: 852.96 Enter
Day 5: 921.37 Enter
Total Sales: \$4067.13
Average Sales: \$813.43

The statement in line 23 dynamically allocates memory for an array of doubles, using the value in numDays as the number of elements. The new operator returns the starting address of the chunk of memory, which is assigned to the sales pointer variable. The sales variable is then used throughout the program to store the sales amounts in the array and perform the necessary calculations. In line 48, the de1ete operator is used to free the allocated memory.

Notice in line 49, the value nul1ptr is assigned to the sales pointer. It is a good practice to set a pointer variable to nullptr after using delete on it. First, it prevents code from inadvertently using the pointer to access the area of memory that was freed. Second, it prevents errors from occurring if delete is accidentally called on the pointer again. The delete operator is designed to have no effect when used on a null pointer.

\subsection*{9.9 Returning Pointers from Functions}

CONCEPT: Functions can return pointers, but you must be sure the item the pointer references still exists.

Like any other data type, functions may return pointers. For example, the following function locates the null terminator that appears at the end of a string (such as a string literal) and returns a pointer to it:
```

char *findNul1(char *str)
{
char *ptr = str;
while (*ptr != '\0')
ptr++;
return ptr;
}

```

The char * return type in the function header indicates the function returns a pointer to a char.
```

char *findNull(char *str)

```

When writing functions that return pointers, you should take care not to create elusive bugs. For instance, see if you can determine what's wrong with the following function:
```

string *getFul1Name()
{
string fullName[3];
cout << "Enter your first name: ";
getline(cin, fullName[0]);
cout << "Enter your middle name: ";
getline(cin, ful1Name[1]);
cout << "Enter your last name: ";
get1ine(cin, ful1Name[2]);
return fullName;
}

```

The problem, of course, is that the function returns a pointer to an array that no longer exists. Because the fullName array is defined locally, it is destroyed when the function terminates. Attempting to use the pointer will result in erroneous and unpredictable results.

You should return a pointer from a function only if it is:
- A pointer to an item that was passed into the function as an argument.
- A pointer to a dynamically allocated chunk of memory.

For instance, the following function is acceptable:
```

string *getFullName(string fullName[])
{
cout << "Enter your first name: ";
getline(cin, fullName[0]);
cout << "Enter your middle name: ";
getline(cin, fullName[1]);
cout << "Enter your last name: ";
getline(cin, fullName[2]);
return fullName;
}

```

This function accepts a pointer to the memory location where the user's input is to be stored. Because the pointer references a memory location that was valid prior to the function being called, it is safe to return a pointer to the same location. Here is another acceptable function:
```

string *getFul1Name()
{
string *fullName = new string[3];
cout << "Enter your first name: ";
getline(cin, fullName[0]);
cout << "Enter your middle name: ";
getline(cin, fullName[1]);
cout << "Enter your last name: ";
getline(cin, fullName[2]);
return fullName;
}

```

This function uses the new operator to allocate a section of memory. This memory will remain allocated until the delete operator is used or the program ends, so it's safe to return a pointer to it.

Program 9-15 shows another example. This program uses a function, getRandomNumbers, to get a pointer to an array of random numbers. The function accepts an integer argument that is the number of random numbers in the array. The function dynamically allocates an array, uses the system clock to seed the random number generator, populates the array with random values, then returns a pointer to the array.

\section*{Program 9-15}
```

// This program demonstrates a function that returns
// a pointer.
\#include <iostream>
\#include <cstdlib> // For rand and srand
\#include <ctime> // For the time function
using namespace std;
// Function prototype
int *getRandomNumbers(int);

```

\section*{Program 9-15 (continued)}
```

int main()
{
int *numbers = nullptr; // To point to the numbers
// Get an array of five random numbers.
numbers = getRandomNumbers(5);
// Display the numbers.
for (int count = 0; count < 5; count++)
cout << numbers[count] << endl;
// Free the memory.
delete [] numbers;
numbers = nullptr;
return 0;
}
//****************************************************
// The getRandomNumbers function returns a pointer *
// to an array of random integers. The parameter
// indicates the number of numbers requested.
/|*****************************************************
int *getRandomNumbers(int num)
{
int *arr = nullptr; // Array to hold the numbers
// Return a null pointer if num is zero or negative.
if (num <= 0)
return nullptr;
// Dynamically allocate the array.
arr = new int[num];
// Seed the random number generator by passing
// the return value of time(0) to srand.
srand( time(0) );
// Populate the array with random numbers.
for (int count = 0; count < num; count++)
arr[count] = rand();
// Return a pointer to the array.
return arr;
}

```

\section*{Program Output}

\section*{In the Spotlight:}

Suppose you are developing a program that works with arrays of integers, and you find that you frequently need to duplicate the arrays. Rather than rewriting the array-duplicating code each time you need it, you decide to write a function that accepts an array and its size as arguments, creates a new array that is a copy of the argument array, and returns a pointer to the new array. The function will work as follows:
Accept an array and its size as arguments.
Dynamically allocate a new array that is the same size as the argument array.
Copy the elements of the argument array to the new array.
Return a pointer to the new array.
Program 9-16 demonstrates the function, which is named duplicateArray.

\section*{Program 9-16}
```

// This program uses a function to duplicate
// an int array of any size.
\#include <iostream>
using namespace std;
// Function prototype
int *duplicateArray(const int *, int);
void displayArray(const int[], int);
int main()
{
// Define constants for the array sizes.
const int SIZE1 = 5, SIZE2 = 7, SIZE3 = 10;
// Define three arrays of different sizes.
int array1[SIZE1] = { 100, 200, 300, 400, 500 };
int array2[SIZE2] = { 10, 20, 30, 40, 50, 60, 70 };
int array3[SIZE3] = { 1, 2, 3, 4, 5, 6, 7, 8, 9, 10 };
// Define three pointers for the duplicate arrays.
int *dup1 = nullptr, *dup2 = nullptr, *dup3 = nullptr;
// Duplicate the arrays.
dup1 = duplicateArray(array1, SIZE1);
dup2 = duplicateArray(array2, SIZE2);
dup3 = duplicateArray(array3, SIZE3);
// Display the original arrays.
cout << "Here are the original array contents:\n";
displayArray(array1, SIZE1);
displayArray(array2, SIZE2);
displayArray(array3, SIZE3);
// Display the new arrays.

```

cout << " \nHere are the duplicate arrays: \n";
displayArray(dup1, SIZE1);
displayArray(dup2, SIZE2);
displayArray(dup3, SIZE3);
// Free the dynamically allocated memory and // set the pointers to 0 .
delete [] dup1;
delete [] dup2;
delete [] dup3;
dup1 = nullptr;
dup2 = nullptr;
dup3 = nullptr;
return 0 ;

// The duplicateArray function accepts an int array
// and an int that indicates the array's size. The
// function creates a new array that is a duplicate
// of the argument array and returns a pointer to the *
// new array. If an invalid size is passed, the *
// function returns a null pointer.
```

|/*********************************************************

```
int *duplicateArray(const int *arr, int size)
int *newArray \(=\) nullptr;
// Validate the size. If 0 or a negative
// number was passed, return a null pointer.
if (size <= 0)
return nullptr;
// Allocate a new array.
newArray \(=\) new int[size];
// Copy the array's contents to the
// new array.
for (int index \(=0\); index < size; index++)
newArray[index] = arr[index];
// Return a pointer to the new array.
return newArray;
```

//*****************************************************

```
// The displayArray function accepts an int array
// and its size as arguments and displays the
// contents of the array.

```

void displayArray(const int arr[], int size)

```
void displayArray(const int arr[], int size)
{
    for (int index = 0; index < size; index++)
        cout << arr[index] << " ";
    cout << endl;
}
```

## Program Output

Here are the original array contents:
100200300400500
$10 \quad 20 \quad 30 \quad 40 \quad 50 \quad 60 \quad 70$
12345678910
Here are the duplicate arrays:
100200300400500
$10 \quad 20 \quad 30 \quad 40 \quad 50 \quad 6070$
12345678910
The duplicateArray function appears in lines 59 and 78. The if statement in lines 65 and 66 validates that size contains a valid array size. If size is 0 or less, the function immediately returns nullptr to indicate that an invalid size was passed.

Line 69 allocates a new array and assigns its address to the newArray pointer. Then, the loop in lines 73 and 74 copies the elements of the arr parameter to the new array. Then, the return statement in line 77 returns a pointer to the new array.

## Checkpoint

9.9 Assuming arr is an array of ints, will each of the following program segments display "True" or "False"?
A) if (arr < \&arr[1]) cout << "True";
else cout << "False";
B) if (\&arr[4] < \&arr[1]) cout << "True";
else cout << "False";
C) if (arr != \&arr[2]) cout << "True";
else cout << "False";
D) if (arr != \&arr[0])
cout << "True";
else
cout << "False";
9.10 Give an example of the proper way to call the following function:

```
void makeNegative(int *val)
{
    if (*val > 0)
```

```
    *va1 = -(*va1);
}
```

9.11 Complete the following program skeleton. When finished, the program will ask the user for a length (in inches), then convert that value to centimeters, and display the result. You are to write the function convert. (Note: 1 inch $=2.54 \mathrm{~cm}$. Do not modify function main.)

```
#include <iostream>
#include <iomanip>
using namespace std;
// Write your function prototype here.
int main()
{
    double measurement;
    cout << "Enter a length in inches, and I will convert\n";
    cout << "it to centimeters: ";
    cin >> measurement;
    convert(&measurement);
    cout << fixed << setprecision(4);
    cout << "Value in centimeters: " << measurement << endl;
    return 0;
}
//
// Write the function convert here.
|/
```

9.12 Look at the following array definition:

```
const int numbers[SIZE] = { 18, 17, 12, 14 };
```

Suppose we want to pass the array to the function processArray in the following manner:

```
processArray(numbers, SIZE);
```

Which of the following function headers is the correct one for the processArray function?
A) void processArray (const int *arr, int size)
B) void processArray(int * const arr, int size)
9.13 Assume ip is a pointer to an int. Write a statement that will dynamically allocate an integer variable and store its address in ip. Write a statement that will free the memory allocated in the statement you wrote above.
9.14 Assume ip is a pointer to an int. Then, write a statement that will dynamically allocate an array of 500 integers and store its address in ip . Write a statement that will free the memory allocated in the statement you just wrote.
9.15 What is a null pointer?
9.16 Give an example of a function that correctly returns a pointer.
9.17 Give an example of a function that incorrectly returns a pointer.

### 9.10 Using Smart Pointers to Avoid Memory Leaks

CONCEPT: C++ 11 introduces smart pointers, objects that work like pointers, but have the ability to automatically delete dynamically allocated memory that is no longer being used.

In C++ 11, you can use smart pointers to dynamically allocate memory and not worry about deleting the memory when you are finished using it. A smart pointer automatically deletes a chunk of dynamically allocated memory when the memory is no longer being used. This helps to prevent memory leaks from occurring.
C++ 11 provides three types of smart pointer: unique_ptr, shared_ptr, and weak_ptr.
These smart pointers are described in Table 9-1.
Table 9-1 Smart Pointer Types

| Smart Pointer Type | Description |
| :--- | :--- |
| unique_ptr | A unique_ptr is the sole owner of a piece of dynamically allocated <br> memory. No two unique_ptrs can point to the same piece of memory. <br> When a unique_ptr goes out of scope, it automatically deallocates the <br> piece of memory that it points to. |
| shared_ptr | A shared_ptr can share ownership of a piece of dynamically allo- <br> cated memory. Multiple pointers of the shared_ptr type can point to <br> the same piece of memory. The memory is deallocated when the last <br> shared_ptr that is pointing to it is destroyed. |
| weak_ptr | A weak_ptr does not own the memory it points to, and cannot be used <br> to access the memory's contents. It is used in special situations where <br> the memory pointed to by a shared_ptr must be referenced without <br> increasing the number of shared_ptrs that own it. |

To use any of the smart pointers, you must \#include the <memory> header file with the following directive:

```
#include <memory>
```

In this book, we introduce unique_ptr. The syntax for defining a unique_ptr is somewhat different from the syntax used in defining a regular pointer. Here is an example:

```
unique_ptr<int> ptr( new int );
```

This statement defines a unique_ptr named ptr that points to a dynamically allocated int. Here are some details about the statement:

- The notation <int> that appears immediately after unique_ptr indicates that the pointer can point to an int.
- The name of the pointer is ptr.
- The expression new int that appears inside the parentheses allocates a chunk of memory to hold an int. The address of the chunk of memory will be assigned to the ptr pointer.

Figure 9-12 shows the different parts of the definition statement.
Figure 9-12 Definition of a unique_ptr

Once you have defined a unique_ptr, you can use it in a similar way as a regular pointer. This is demonstrated in Program 9-17.

## Program 9-17

```
// This program demonstrates a unique_ptr.
#include <iostream>
#include <memory>
using namespace std;
int main()
{
    // Define a unique_ptr smart pointer, pointing
    // to a dynamically allocated int.
    unique_ptr<int> ptr( new int );
    // Assign 99 to the dynamically allocated int.
    *ptr = 99;
        // Display the value of the dynamically allocated int.
        cout << *ptr << endl;
        return 0;
}
```

## Program Output

99

In line 3, we have a \#include directive for the <memory> header file. Line 10 defines a unique_ptr named ptr, pointing to a dynamically allocated int. Line 13 assigns the value 99 to the dynamically allocated int. Notice the indirection operator (*) is used with the unique_ptr, just as if it were a regular pointer. Line 16 displays the value stored in the dynamically allocated int, once again using the indirection operator with the unique_ptr. Notice there is no delete statement to free the dynamically allocated memory. It is unnecessary to delete the memory, because the smart pointer will automatically delete it as the function comes to an end.

Program 9-17 demonstrates a unique_ptr, but it isn't very practical. Dynamically allocating an array is more useful than allocating a single integer. The following code shows an example of how to use a unique_ptr to dynamically allocate an array of integers:

```
const int SIZE = 100;
unique_ptr<int[]> ptr( new int[SIZE] );
```

The first statement defines an int constant named SIZE, set to the value 100 . The second statement defines a unique_ptr named ptr that points to a dynamically allocated array of 100 ints. Notice the following things about the definition statement:

- Following unique_ptr, the notation <int[]> indicates that the pointer will point to an array of ints.
- The expression inside the parentheses, new int[SIZE], allocates an array of ints.

The address of the dynamically allocated array of ints will be assigned to the $p t r$ pointer. After the definition statement, you can use the [] operator with subscripts to access the array elements. Here is an example:

```
ptr[0] = 99;
cout << ptr[0] << endl;
```

The first statement assigns the value 99 to ptr[0], and the second statement displays the value of $\operatorname{ptr}[0]$. Program 9-18 gives a more complete demonstration.

## Program 9-18

```
// This program demonstrates a unique_ptr pointing
// to a dynamically allocated array of integers.
#include <iostream>
#include <memory>
using namespace std;
int main()
{
    int max; // Max size of the array
    // Get the number of values to store.
    cout << "How many numbers do you want to enter? ";
    cin >> max;
    // Define a unique_ptr smart pointer, pointing
    // to a dynamically allocated array of ints.
    unique_ptr<int[]> ptr( new int[max]);
    // Get values for the array.
    for (int index = 0; index < max; index++)
    {
        cout << "Enter an integer number: ";
        cin >> ptr[index];
    }
```

```
Program 9-18 (continued)
```

```
    // Display the values in the array.
```

    // Display the values in the array.
    cout << "Here are the values you entered:\n";
    cout << "Here are the values you entered:\n";
    for (int index = 0; index < max; index++)
    for (int index = 0; index < max; index++)
        cout << ptr[index] << endl;
        cout << ptr[index] << endl;
    return 0;
    return 0;
    }

```
}
```

Program Output with Example Input Shown in Bold
How many numbers do you want to enter? 5 Enter
Enter an integer number: 1 Enter
Enter an integer number: 2 Enter
Enter an integer number: 3 Enter
Enter an integer number: 4 Enter
Enter an integer number: 5 Enter
Here are the values you entered:
1
2
3
4
5

You can define an uninitialized unique_ptr, then assign it a value in a later statement. Here is an example:

```
unique_ptr<int> ptr;
ptr = unique_ptr<int>(new int);
```

Smart pointers support the same * and -> dereferencing operators as regular pointers, but smart pointers do not support pointer arithmetic. The following code will result in a compile-time error:

```
unique_ptr<int[]> ptr( new int[max]);
ptr++; // ERROR!
```

### 9.11 Focus on Problem Solving and Program Design: A Case Study

CONCEPT: This case study demonstrates how an array of pointers can be used to display the contents of a second array in sorted order, without sorting the second array.

The United Cause, a charitable relief agency, solicits donations from businesses. The local United Cause office received the following donations from the employees of CK Graphics, Inc.:
\$5, \$100, \$5, \$25, \$10, \$5, \$25, \$5, \$5, \$100, \$10, \$15, \$10, \$5, \$10

The donations were received in the order they appear. The United Cause manager has asked you to write a program that displays the donations in ascending order, as well as in their original order.

## Variables

Table 9-2 shows the major variables needed.
Table 9-2 Variables

| Variable | Description |
| :--- | :--- |
| NUM_DONATIONS | A constant integer initialized with the number of donations received from CK <br> Graphics, Inc. This value will be used in the definition of the program's arrays. |
| donations <br> arrPtr | An array of integers containing the donation amounts. <br> An array of pointers to integers. This array has the same number of <br> elements as the donations array. Each element of arrPtr will be initialized <br> to point to an element of the donations array. |

## Programming Strategy

In this program, the donations array will contain the donations in the order they were received. The elements of the arrPtr array are pointers to integers. They will point to the elements of the donations array, as illustrated in Figure 9-13.

Figure 9-13 Relationship between the arrays

The arrPtr array will initially be set up to point to the elements of the donations array in their natural order. In other words, $\operatorname{arrPtr}[0]$ will point to donations [0], $\operatorname{arrPtr}[1]$ will point to donations[1], and so forth. In that arrangement, the following statement would cause the contents of donations [5] to be displayed:

```
cout << *(arrPtr[5]) << endl;
```

After the arrPtr array is sorted, however, $\operatorname{arrPtr}[0]$ will point to the smallest element of donations, $\operatorname{arrPtr}[1]$ will point to the next-to-smallest element of donations, and so forth. This is illustrated in Figure 9-14.

Figure 9-14 Accessing the donations array elements in sorted order

This technique gives us access to the elements of the donations array in a sorted order without actually disturbing the contents of the donations array itself.

## Functions

The program will consist of the functions listed in Table 9-3.

Table 9-3 Functions

| Function | Description |
| :--- | :--- |
| main | The program's main function. It calls the program's other functions. <br> arrSelectSort <br> Performs an ascending order selection sort on its parameter, arr, which is <br> an array of pointers. Each element of arr points to an element of a second <br> array. After the sort, arr will point to the elements of the second array in <br> ascending order. |
| showArray | Displays the contents of its parameter, arr, which is an array of integers. <br> This function is used to display the donations in their original order. |
| showArrPtr | Accepts an array of pointers to integers as an argument. Displays the <br> contents of what each element of the array points to. This function is <br> used to display the contents of the donations array in sorted order. |

## Function main

In addition to containing the variable definitions, function main sets up the arrPtr array to point to the elements of the donations array. Then, the function arrSelectSort is called to sort the elements of arrPtr. Last, the functions showArrPtr and showArray are called to display the donations. Here is the pseudocode for main's executable statements:

[^2]
## The arrSelectSort Function

The arrSelectSort function is a modified version of the selection sort algorithm shown in Chapter 8. The only difference is that arr is now an array of pointers. Instead of sorting on the contents of arr's elements, arr is sorted on the contents of what its elements point to. Here is the pseudocode:

```
For startScan is set to the values O up to (but not including) the
        next-to-last subscript in arr
    Set index variable to startScan
    Set minIndex variable to startScan
    Set minElem pointer to arr[startScan]
    For index variable is set to the values from (startScan + 1) through
                        the last subscript in arr
        If *(arr[index]) is less than *minElem
            Set minElem to arr[index]
            Set minIndex to index
        End If
    End For
    Set arr[minIndex] to arr[startScan]
    Set arr[startScan] to minElem
End For
```

## The showArrPtr Function

The showArrPtr function accepts an array of pointers as its argument. It displays the values pointed to by the elements of the array. Here is its pseudocode:

```
For every element in the arr
    Dereference the element and display what it points to
End For.
```

## The showArray Function

The showArray function simply displays the contents of arr sequentially. Here is its pseudocode:

```
For every element in arr
    Display the element's contents
End For.
```

## The Entire Program

Program 9-19 shows the entire program's source code.

## Program 9-19

1 // This program shows the donations made to the United Cause
2 // by the employees of CK Graphics, Inc. It displays
3 // the donations in order from lowest to highest

## Program 9-19

```
// and in the original order they were received.
#include <iostream>
using namespace std;
// Function prototypes
void arrSelectSort(int *[], int);
void showArray(const int [], int);
void showArrPtr(int *[], int);
int main()
{
    const int NUM_DONATIONS = 15; // Number of donations
    // An array containing the donation amounts.
    int donations[NUM_DONATIONS] = { 5, 100, 5, 25, 10,
                                    5, 25, 5, 5, 100,
                                    10, 15, 10, 5, 10 };
    // An array of pointers to int.
        int *arrPtr[NUM_DONATIONS] = { nul1ptr, nul1ptr, nul1ptr, nul1ptr, nul1ptr,
                                    nullptr, nullptr, nullptr, nullptr, nullptr,
                                    nullptr, nullptr, nullptr, nullptr, nullptr};
    // Each element of arrPtr is a pointer to int. Make each
    // element point to an element in the donations array.
    for (int count = 0; count < NUM_DONATIONS; count++)
            arrPtr[count] = &donations[count];
    // Sort the elements of the array of pointers.
    arrSelectSort(arrPtr, NUM_DONATIONS);
    // Display the donations using the array of pointers. This
    // will display them in sorted order.
    cout << "The donations, sorted in ascending order, are: \n";
    showArrPtr(arrPtr, NUM_DONATIONS);
    // Display the donations in their original order.
    cout << "The donations, in their original order, are: \n";
    showArray(donations, NUM_DONATIONS);
    return O;
}
//******************************************************************
// Definition of function arrSelectSort.
// This function performs an ascending order selection sort on *
// arr, which is an array of pointers. Each element of array *
// points to an element of a second array. After the sort, *
// arr will point to the elements of the second array in *
// ascending order. *
//*******************************************************************
```

54

```
void arrSelectSort(int *arr[], int size)
{
    int startScan, minIndex;
    int *minElem;
    for (startScan = 0; startScan < (size - 1); startScan++)
    {
        minIndex = startScan;
        minElem = arr[startScan];
        for(int index = startScan + 1; index < size; index++)
        {
            if (*(arr[index]) < *minElem)
            {
                minElem = arr[index];
                minIndex = index;
            }
        }
        arr[minIndex] = arr[startScan];
        arr[startScan] = minElem;
    }
}
//**************************************************************
// Definition of function showArray.
// This function displays the contents of arr. size is the *
// number of elements.
//*
void showArray(const int arr[], int size)
{
    for (int count = 0; count < size; count++)
        cout << arr[count] << " ";
    cout << endl;
}
//******************************************************************
// Definition of function showArrPtr.
// This function displays the contents of the array pointed to *
// by arr. size is the number of elements.
//*****************************************************************
void showArrPtr(int *arr[], int size)
{
    for (int count = 0; count < size; count++)
        cout << *(arr[count]) << " ";
    cout << endl;
}
```

## Program Output

The donations, sorted in ascending order, are:
$5551555101010101525 \quad 25100100$
The donations, in their original order, are:
51005251052555100101510510

## Review Questions and Exercises

## Short Answer

1. What does the indirection operator do?
2. Look at the following code.
```
int x = 7;
int *iptr = &x;
```

What will be displayed if you send the expression *iptr to cout? What happens if you send the expression ptr to cout?
3. So far you have learned three different uses for the * operator. What are they?
4. What math operations are allowed on pointers?
5. Assuming ptr is a pointer to an int, what happens when you add 4 to ptr?
6. Look at the following array definition.
int numbers[] $=\{2,4,6,8,10\}$;
What will the following statement display?

```
cout << *(numbers + 3) << endl;
```

7. What is the purpose of the new operator?
8. What happens when a program uses the new operator to allocate a block of memory, but the amount of requested memory isn't available? How do programs written with older compilers handle this?
9. What is the purpose of the delete operator?
10. Under what circumstances can you successfully return a pointer from a function?
11. What is the difference between a pointer to a constant and a constant pointer?
12. What are two advantages of declaring a pointer parameter as a constant pointer?

## Fill-in-the-Blank

13. Each byte in memory is assigned a unique $\qquad$ .
14. The statement ptr $=$ \&num assigns the $\qquad$ of num to the pointer $p t r$.
15. The statement cout << * (\&num) prints the $\qquad$ of the variable num.
16. A(n) $\qquad$ can hold the address of an integer variable.
17. Array names can be used as $\qquad$ , and vice versa.
18. Creating variables while a program is running is called $\qquad$ .
19. The $\qquad$ operator is used to dynamically allocate memory.
20. Under older compilers, if the new operator cannot allocate the amount of memory requested, it returns $\qquad$ .
21. A pointer that contains the address 0 is called a(n) $\qquad$ pointer.
22. The $\qquad$ operator is used to release the amount of memory that was dynamically created using the $\qquad$ operator.
23. You should only use pointers with delete that were previously used with $\qquad$ .

## Algorithm Workbench

24. Look at the following code:
double value = 29.7;
double *ptr = \&value;
Write a cout statement that uses the ptr variable to display the contents of the value variable.
25. Look at the following function call.
iptr $=$ someFunc ( $x, \& y$ );
If x and y are integers and iptr is a pointer to an integer, write the function prototype.
26. Write code to dynamically allocate an integer array, allow the user to input the array elements, find their mean, and finally release the memory used by the array.
27. Write a single statement that displays the value pointed by a pointer xptr, and then increments the pointer xptr.
28. Look at the following function definition:
```
void assign ( int *numbers, int size )
{
    for ( int i = 0 ; i < size ; i++ )
        cin >> numbers[i];
}
```

Write code showing how you can call this function. Also, rewrite the cin statement to show an alternative way to input elements in the array.
29. Write the definition of $p t r$, a pointer to a constant int.
30. Write code to display a two-dimensional array arr [5] [10], using pointer notation.

## True or False

## 31. T F Each byte of memory is assigned a unique address.

32. T F The * operator is used to get the address of a variable.
33. T F A pointer variable can be incremented and decremented.
34. T F The \& symbol is called the indirection operator.
35. T F The statement const double *dptr indicates that dptr is a constant pointer.
36. T F When the indirection operator is used with a pointer variable, you are actually working with the value the pointer is pointing to.
37. T F Array names cannot be dereferenced with the indirection operator.
38. T F When you add a value to a pointer, you are actually adding that number times the size of the data type referenced by the pointer.
39. T F A constant pointer implies a pointer to a constant variable.
40. T F You can change the address that an array name points to.
41. T F Any mathematical operation, including multiplication and division, may be performed on a pointer.
42. T F Once a constant pointer is initialized with an address, it cannot point to anything else.
43. T F Though a function can accept pointer variables as arguments, a function can never return a pointer.
44. T F The new operator dynamically allocates memory.
45. T F A pointer variable that has not been initialized is called a null pointer.
46. T F The address 0 is generally considered unusable.
47. T F A smart pointer can automatically delete a dynamically allocated memory when it is not in use anymore, without the need of the delete operator to be explicitly called to do so.

## Find the Error

Each of the following definitions and program segments has errors. Locate as many as you can.
48. double *dptr = *nullptr;
49. int $x$, *ptr $=$ nullptr;
\& $x$ = ptr;
50. int ptr, value=9;
ptr = \&value;
51. int $x,{ }^{*} p t r=n u l p t r$;
ptr = \&x;
ptr = 100; // Store 100 in x
cout << x << endl;
52. float numbers[] $=\{2.3,3.4,4.5,5.6,6.7\}$;
cout << "The second element in the list of numbers is :";
cout << (*numbers++) << endl;
53. int values[20], *iptr = nullptr;
iptr = values;
iptr *= 2;
54. float level;
int fptr = \&level;
55. float values[6] = $\{1,2,3,4,5,6\}$;
cout << *(values + 1.5) << endl;
56. void doubleVal (int val)
\{
*val *= 2;
\}
57. int *pint $=$ nullptr;
new pint;
58. int *pint $=$ nullptr;
pint = new int;
if (pint == nullptr)
*pint $=100$;
else
cout << "Memory allocation errorln";

```
59. int *pint = nullptr;
    pint = new int[100]; // Allocate memory
```

Code that processes the array.

```
    delete pint; // Free memory
```

60. int *getNum()
\{
int wholeNum;
cout << "Enter a number: ";
cin >> wholeNum;
return \&wholeNum;
\}
61. const int $\operatorname{arr}[]=\{1,2,3\} ;$
int *ptr = arr;
62. void doSomething(int * const ptr)
\{
int localArray[] = \{ 1, 2, 3 \};
ptr = localArray;
\}

## Programming Challenges

## 1. Address of Elements in an Array

Write a program to initialize an array of integers with 10 numbers. The program should then display the number of bytes occupied by the array. Also display each element as well as the address in which it is stored.

## 2. Test Scores \#1

Write a program that dynamically allocates an array large enough to hold a userdefined number of test scores. Once all the scores are entered, the array should be passed to a function that sorts them in ascending order. Another function should be called that calculates the average score. The program should display the sorted list of scores and averages with appropriate headings. Use pointer notation rather than array notation whenever possible.

Input Validation: Do not accept negative numbers for test scores.

## 3. Drop Lowest Score

Modify Problem 2 above so the lowest test score is dropped. This score should not be included in the calculation of the average.

## 4. Test Scores \#2

Modify the program of Programming Challenge 2 (Test Scores \#1) to allow the user to enter name-score pairs. For each student taking a test, the user types the student's name followed by the student's integer test score. Modify the sorting function so it takes an array holding the student names, and an array holding the student test scores. When the sorted list of scores is displayed, each student's name should be displayed along with his or her score. In stepping through the arrays, use pointers rather than array subscripts.

## 5. Pointer Rewrite

The following function uses reference variables as parameters. Rewrite the function so it uses pointers instead of reference variables, then demonstrate the function in a complete program.

```
int doSomething(int &x, int &y)
{
    int temp = x;
    x = y * 10;
    y = temp * 10;
    return x + y;
}
```

6. Case Study Modification \#1

Modify Program 9-19 (the United Cause case study program) so it can be used with any set of donations. The program should dynamically allocate the donations array and ask the user to input its values.

## 7. Case Study Modification \#2

Modify Program 9-19 (the United Cause case study program) so the arrptr array is sorted in descending order instead of ascending order.

## 8. Mode Function

In statistics, the mode of a set of values is the value that occurs most often or with the greatest frequency. Write a function that accepts as arguments the following:
A) An array of integers
B) An integer that indicates the number of elements in the array

The function should determine the mode of the array. That is, it should determine which value in the array occurs most often. The mode is the value the function should return. If the array has no mode (none of the values occur more than once), the function should return -1 . (Assume the array will always contain nonnegative values.)
Demonstrate your pointer prowess by using pointer notation instead of array notation in this function.

## 9. Median Function

In statistics, when a set of values is sorted in ascending or descending order, its median is the middle value. If the set contains an even number of values, the median is the
mean, or average, of the two middle values. Write a function that accepts as arguments the following:
A) An array of integers
B) An integer that indicates the number of elements in the array

The function should determine the median of the array. This value should be returned as a double. (Assume the values in the array are already sorted.)
Demonstrate your pointer prowess by using pointer notation instead of array notation in this function.

## 10. Array Splitter

Write a function that accepts an int array and the array's size as arguments. The function should return a new array consisting of the values at even positions in the original array, that is, elements $0,2,4,6,8$, and so on. The function should return a pointer to the new array. Demonstrate the function in a complete program.

## 11. Array Joiner

Write a function that accepts two int arrays and their sizes as arguments. The function should return a new array consisting of the values of both arrays. The elements of the second array should be joined after the elements of the first array. The function should return a pointer to the new array. Demonstrate the function in a complete program.

## 12. Array Filter

Write a function that accepts three arguments: an int array, its size, and an int variable. The function should return a new array consisting of only those values in the original array that are a multiple of the third argument. For example, if the third argument is 7 , only those values from the original array that are multiples of 7 should be in the new array. First calculate the size of the new array and then copy the correct values. The function should return a pointer to the new array.

## 13. Movie Statistics

Write a program that can be used to gather statistical data about the number of movies college students see in a month. The program should perform the following steps:
A) Ask the user how many students were surveyed. An array of integers with this many elements should then be dynamically allocated.
B) Allow the user to enter the number of movies each student saw into the array.
C) Calculate and display the average, median, and mode of the values entered. (Use the functions you wrote in Programming Challenges 8 and 9 to calculate the median and mode.)
Input Validation: Do not accept negative numbers for input.

### 10.1 Character Testing

CONCEPT: The C++ library provides several functions for testing characters. To use these functions you must include the <cctype> header file.

The C++ library provides several functions that allow you to test the value of a character. These functions test a single char argument and return either true or false.* For example, the following program segment uses the isupper function to determine whether the character passed as an argument is an uppercase letter. If it is, the function returns true. Otherwise, it returns false.

```
char letter = 'a';
if (isupper(letter))
    cout << "Letter is uppercase.\n";
else
    cout << "Letter is lowercase.\n";
```

Because the variable letter, in this example, contains a lowercase character, isupper returns false. The if statement will cause the message "Letter is lowercase" to be displayed.

[^3]Table 10-1 lists several character-testing functions. Each of these is prototyped in the <cctype> header file, so be sure to include that file when using the functions.

Table 10-1 Character-Testing Functions in <cctype>

| Character <br> Function | Description |
| :---: | :---: |
| isalpha | Returns true (a nonzero number) if the argument is a letter of the alphabet. Returns 0 if the argument is not a letter. |
| isalnum | Returns true (a nonzero number) if the argument is a letter of the alphabet or a digit. Otherwise, it returns 0 . |
| isdigit | Returns true (a nonzero number) if the argument is a digit from 0 through 9 . Otherwise, it returns 0 . |
| islower | Returns true (a nonzero number) if the argument is a lowercase letter. Otherwise, it returns 0 . |
| isprint | Returns true (a nonzero number) if the argument is a printable character (including a space). Returns 0 otherwise. |
| ispunct | Returns true (a nonzero number) if the argument is a printable character other than a digit, letter, or space. Returns 0 otherwise. |
| isupper | Returns true (a nonzero number) if the argument is an uppercase letter. Otherwise, it returns 0 . |
| isspace | Returns true (a nonzero number) if the argument is a whitespace character. Whitespace characters are any of the following: <br> space ' ' <br> vertical tab ' $\backslash \mathrm{v}$ ' <br> newline ' n ' <br> tab ' $\backslash \mathrm{t}$ ' <br> Otherwise, it returns 0 . |

Program 10-1 uses several of the functions shown in Table 10-1. It asks the user to input a character then displays various messages, depending upon the return value of each function.

## Program 10-1

```
// This program demonstrates some character-testing functions.
#include <iostream>
#include <cctype>
using namespace std;
int main()
{
    char input;
    cout << "Enter any character: ";
    cin.get(input);
    cout << "The character you entered is: " << input << endl;
```

```
13 if (isalpha(input))
14 cout << "That's an alphabetic character.\n";
15
16
1 7
18
19
20
21
22
23
    if (isdigit(input))
        cout << "That's a numeric digit.\n";
    if (islower(input))
        cout << "The letter you entered is lowercase.\n";
    if (isupper(input))
        cout << "The letter you entered is uppercase.\n";
    if (isspace(input))
        cout << "That's a whitespace character.\n";
    return 0;
}
```

## Program Output with Example Input Shown in Bold

Enter any character: A Enter
The character you entered is: A
That's an alphabetic character.
The letter you entered is uppercase.

## Program Output with Different Example Input Shown in Bold

Enter any character: 7 Enter
The character you entered is: 7
That's a numeric digit.

Program 10-2 shows a more practical application of the character-testing functions. It tests a seven-character customer number to determine whether it is in the proper format.

## Program 10-2

```
// This program tests a customer number to determine whether
// it is in the proper format.
#include <iostream>
#include <cctype>
using namespace std;
// Function prototype
bool testNum(char [], int);
int main()
{
    const int SIZE = 8; // Array size
    char customer[SIZE]; // To hold a customer number
    // Get the customer number
    cout << "Enter a customer number in the form ";
    cout << "LLLNNNN\n";
    cout << "(LLL = letters and NNNN = numbers): ";
    cin.getline(customer, SIZE);
```

## Program 10-2 (continued)

```
    // Determine whether it is valid.
    if (testNum(customer, SIZE))
        cout << "That's a valid customer number.\n";
    else
    {
        cout << "That is not the proper format of the ";
        cout << "customer number. \nHere is an example:\n";
        cout << " ABC1234\n";
    }
    return 0;
}
//************************************************************
// Definition of function testNum.
// This function determines whether the custNum parameter
// holds a valid customer number. The size parameter is *
// the size of the custNum array.
/|***********************************************************
bool testNum(char custNum[], int size)
{
    int count; // Loop counter
    // Test the first three characters for alphabetic letters.
    for (count = 0; count < 3; count++)
    {
        if (!isalpha(custNum[count]))
            return false;
    }
    // Test the remaining characters for numeric digits.
    for (count = 3; count < size - 1; count++)
    {
        if (!isdigit(custNum[count]))
            return false;
        }
        return true;
}
```

## Program Output with Example Input Shown in Bold

Enter a customer number in the form LLLNNNN
(LLL = letters and NNNN = numbers): RQS4567 Enter
That's a valid customer number.

## Program Output with Different Example Input Shown in Bold

Enter a customer number in the form LLLNNNN
(LLL $=$ letters and NNNN = numbers): AX467T9 Enter
That is not the proper format of the customer number.
Here is an example:
ABC1234

In this program, the customer number is expected to consist of three alphabetic letters followed by four numeric digits. The testNum function accepts an array argument and tests the first three characters with the following loop in lines 45 through 49:

```
for (count = 0; count < 3; count++)
{
    if (!isalpha(custNum[count]))
    return false;
}
```

The isalpha function returns true if its argument is an alphabetic character. The ! operator is used in the if statement to determine whether the tested character is NOT alphabetic. If this is so for any of the first three characters, the function testNum returns false. Likewise, the next four characters are tested to determine whether they are numeric digits with the following loop in lines 52 through 56:

```
for (count = 3; count < size - 1; count++)
{
    if (!isdigit(custNum[count]))
    return false;
}
```

The isdigit function returns true if its argument is the character representation of any of the digits 0 through 9 . Once again, the ! operator is used to determine whether the tested character is not a digit. If this is so for any of the last four characters, the function testNum returns false. If the customer number is in the proper format, the function will cycle through both the loops without returning false. In that case, the last line in the function is the return true statement, which indicates the customer number is valid.

### 10.2 Character Case Conversion

CONCEPT: The C++ library offers functions for converting a character to uppercase or lowercase.

The C++ library provides two functions, toupper and tolower, for converting the case of a character. The functions are described in Table 10-2. (These functions are prototyped in the header file <cctype>, so be sure to include it.)

Table 10-2 Case-Conversion Functions in <cctype>

| Function | Description |
| :--- | :--- |
| toupper | Returns the uppercase equivalent of its argument. |
| tolower | Returns the lowercase equivalent of its argument. |

Each of the functions in Table 10-2 accepts a single character argument. If the argument is a lowercase letter, the toupper function returns its uppercase equivalent. For example, the following statement will display the character A on the screen:

```
cout << toupper('a');
```

If the argument is already an uppercase letter, toupper returns it unchanged. The following statement causes the character Z to be displayed:

```
cout << toupper('Z');
```

Any nonletter argument passed to toupper is returned as it is. Each of the following statements displays toupper's argument without any change:

```
cout << toupper('*'); // Displays *
cout << toupper ('&'); // Displays &
cout << toupper('%'); // Displays %
```

toupper and tolower don't actually cause the character argument to change; they simply return the uppercase or lowercase equivalent of the argument. For example, in the following program segment, the variable letter is set to the value ' A '. The tolower function returns the character ' $a$ ', but letter still contains ' $A$ '.

```
char letter = 'A';
cout << tolower(letter) << endl;
cout << letter << endl;
```

These statements will cause the following to be displayed:

## a

A
Program 10-3 demonstrates the toupper function in an input validation loop.

## Program 10-3

```
// This program calculates the area of a circle. It asks the user
// if he or she wishes to continue. A loop that demonstrates the
// toupper function repeats until the user enters 'y', 'Y',
// 'n', or 'N'.
#include <iostream>
#include <cctype>
#include <iomanip>
using namespace std;
int main()
{
    const double PI = 3.14159; // Constant for pi
    double radius; // The circle's radius
    char goAgain; // To hold Y or N
    cout << "This program calculates the area of a circle.\n";
    cout << fixed << setprecision(2);
    do
    {
            // Get the radius and display the area.
            cout << "Enter the circle's radius: ";
            cin >> radius;
            cout << "The area is " << (PI * radius * radius);
            cout << endl;
```

26
27
28
29
30
31
32
33
34
35
36
37
38
39
40
// Does the user want to do this again?
cout << "Calculate another? (Y or N) ";
cin >> goAgain;
// Validate the input.
while (toupper(goAgain) != 'Y' \&\& toupper(goAgain) != 'N')
\{
cout << "Please enter $Y$ or $N$ : ";
cin >> goAgain;
\}
\} while (toupper(goAgain) == 'Y');
return 0;
\}

## Program Output with Example Input Shown in Bold

This program calculates the area of a circle.
Enter the circle's radius: 10 Enter
The area is 314.16
Calculate another? ( $Y$ or $N$ ) ben Enter
Please enter $Y$ or $N$ : $y$ Enter
Enter the circle's radius: 1 Enter
The area is 3.14
Calculate another? (Y or $N$ ) $n$ Enter

In lines 28 and 29, the user is prompted to enter either Y or N to indicate whether he or she wants to calculate another area. We don't want the program to be so picky that it accepts only uppercase Y or uppercase N . Lowercase y or lowercase n is also acceptable. The input validation loop must be written to reject anything except ' Y ', ' $\mathrm{y}^{\prime}$, ' N ', or ' n '. One way to do this would be to test the goAgain variable in four relational expressions, as shown here:

```
while (goAgain != 'Y' && goAgain != 'y' &&
    goAgain != 'N' && goAgain != 'N')
```

Although there is nothing wrong with this code, we could use the toupper function to get the uppercase equivalent of goAgain and make only two comparisons. This is the approach taken in line 32:

```
while (toupper(goAgain) != 'Y' && toupper(goAgain) != 'N')
```

Another approach would have been to use the tolower function to get the lowercase equivalent of goAgain. Here is an example:

```
while (tolower(goAgain) != 'y' && tolower(goAgain) != 'n')
```

Either approach will yield the same results.

## (1) Checkpoint

10.1 Write a short description of each of the following functions:

```
isalpha
isalnum
isdigit
islower
isprint
ispunct
isupper
isspace
toupper
tolower
```

10.2 Write a statement that will convert the contents of the char variable big to lowercase. The converted value should be assigned to the variable little.
10.3 Write an if statement that will display the word "digit" if the variable ch contains a numeric digit. Otherwise, it should display "Not a digit."
10.4 What is the output of the following statement?
cout << toupper(tolower('A'));
10.5 Write a loop that asks the user "Do you want to repeat the program or quit? (R/Q)". The loop should repeat until the user has entered an R or a Q (either uppercase or lowercase).

### 10.3 C-Strings

CONCEPT: In C++, a C-string is a sequence of characters stored in consecutive memory locations, terminated by a null character.

String is a generic term that describes any consecutive sequence of characters. A word, a sentence, a person's name, and the title of a song are all strings. In the C++ language, there are two primary ways that strings are stored in memory: as string objects or as C-strings. You have already been introduced to the string class, and by now, you have written several programs that use string objects. In this section, we will use C-strings, which are an alternative method for storing and working with strings.

A C-string is a string whose characters are stored in consecutive memory locations and are followed by a null character, or null terminator. Recall from Chapter 2 that a null character or null terminator is a byte holding the ASCII code 0 . Strings that are stored this way are called C -strings because this is the way strings are handled in the C programming language.

In C++, all string literals are stored in memory as C-strings. Recall that a string literal (or string constant) is the literal representation of a string in a program. In C++, string literals are enclosed in double quotation marks, such as:
"Bailey"

Figure 10-1 illustrates how the string literal "Bailey" is stored in memory, as a C-string.
Figure 10-1 A C-string stored in memory

| $B$ | $a$ | $i$ | $l$ | $e$ | $y$ | 10 |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |

NOTE: Remember that 10 ("slash zero") is the escape sequence representing the null terminator. It stands for the ASCII code 0 .

The purpose of the null terminator is to mark the end of the C-string. Without it, there would be no way for a program to know the length of a C -string.

## More about String Literals

A string literal or string constant is enclosed in a set of double quotation marks (" "). For example, here are five string literals:

```
"Have a nice day."
"What is your name?"
"John Smith"
"Please enter your age:"
"Part Number 45Q1789"
```

All of a program's string literals are stored in memory as C-strings, with the null terminator automatically appended. For example, look at Program 10-4.

## Program 10-4

// This program contains string literals.
\#include <iostream>

```
using namespace std;
```

int main()
\{
char again;
do
\{
cout << "C++ programming is great fun!" << endl;
cout << "Do you want to see the message again? ";
cin >> again;
\} while (again == 'Y' || again == 'y');
return 0;
\}

This program contains two string literals:

```
"C++ programming is great fun!"
"Do you want to see the message again? "
```

The first string occupies 30 bytes of memory (including the null terminator), and the second string occupies 39 bytes. They appear in memory in the following forms:

| D | $\bigcirc$ |  | y | o | u |  | w | a | n | t | t | o | S | e | e | t | h | e | m | e | S | S | a | g | g |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| e |  | a | g | a | i | n | ? |  | 10 |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |

It's important to realize that a string literal has its own storage location, just like a variable or an array. When a string literal appears in a statement, it's actually its memory address that C++ uses. Look at the following example:

```
cout << "Do you want to see the message again? ";
```

In this statement, the memory address of the string literal "Do you want to see the message again?" is passed to the cout object. cout displays the consecutive characters found at this address. It stops displaying the characters when a null terminator is encountered.

## C-Strings Stored in Arrays

The C programming language does not provide a string class like that which C++ provides. In the C language, all strings are treated as C -strings. When a C programmer wants to store a string in memory, he or she has to create a char array that is large enough to hold the string, plus one extra element for the null character.

You might be wondering why this should matter to anyone learning C++. You need to know about C -strings for the following reasons:

- The string class has not always existed in the C++ language. Several years ago, C++ stored strings as C-strings. As a professional programmer, you might encounter older $\mathrm{C}++$ code (known as legacy code) that uses C-strings.
- Some of the C++ library functions work only with C-strings.
- In the workplace, it is not unusual for C++ programmers to work with specialized libraries that are written in C. Any strings with which C libraries work will be C-strings.

As previously mentioned, if you want to store a C-string in memory, you have to define a char array that is large enough to hold the string, plus one extra element for the null character. Here is an example:

```
const int SIZE = 21;
char name[SIZE];
```

This code defines a char array that has 21 elements, so it is big enough to hold a C-string that is no more that 20 characters long.
You can initialize a char array with a string literal, as shown here:

```
const int SIZE = 21;
char name[SIZE] = "Jasmine";
```

After this code executes, the name array will be created with 21 elements. The first eight elements will be initialized with the characters 'J', 'a', 's', 'm', 'i', 'n', 'e', and 'l0'. The null character is automatically added as the last character. You can implicitly size a char array by initializing it with a string literal, as shown here:

```
char name[] = "Jasmine";
```

After this code executes, the name array will be created with eight elements, initialized with the characters 'J','a', 's', 'm', 'i', 'n', 'e', and '\0'.
C-string input can be performed by the cin object. For example, the following code allows the user to enter a string (with no whitespace characters) into the name array:

```
const int SIZE = 21;
char name[SIZE];
cin >> name;
```

Recall from Chapter 7 that an array name with no brackets and no subscript is converted into the beginning address of the array. In the previous statement, name indicates the address in memory where the string is to be stored. Of course, cin has no way of knowing that name has 21 elements. If the user enters a string of 30 characters, cin will write past the end of the array. This can be prevented by using cin's getline member function. Assume the following array has been defined in a program:

```
const int SIZE = 80;
char line[SIZE];
```

The following statement uses cin's get 1 ine member function to get a line of input (including whitespace characters) and store it in the line array:

```
cin.getline(line, SIZE);
```

The first argument tells getline where to store the string input. This statement indicates the starting address of the line array as the storage location for the string. The second argument indicates the maximum length of the string, including the null terminator. In this example, the SIZE constant is equal to 80 , so cin will read 79 characters, or until the user presses the Enter key, whichever comes first. cin will automatically append the null terminator to the end of the string.

Once a string is stored in an array, it can be processed using standard subscript notation. For example, Program 10-5 displays a string stored in an array. It uses a loop to display each character in the array until the null terminator is encountered.

## Program 10-5

```
// This program displays a string stored in a char array.
#include <iostream>
using namespace std;
int main()
{
    const int SIZE = 80; // Array size
    char line[SIZE]; // To hold a line of input
    int count = 0; // Loop counter variable
    // Get a line of input.
    cout << "Enter a sentence of no more than "
        << (SIZE - 1) << " characters:\n";
    cin.getline(1ine, SIZE);
```

## Program 10-5 (continued)

17

```
```

16 // Display the input one character at a time.

```
```

```
16 // Display the input one character at a time.
```

```
    cout << "The sentence you entered is:\n";
```

    cout << "The sentence you entered is:\n";
    while (line[count] != '\0')
    while (line[count] != '\0')
    {
    {
        cout << line[count];
        cout << line[count];
        count++;
        count++;
        }
        }
        return 0;
        return 0;
    }

```

\section*{Program Output with Example Input Shown in Bold}

Enter a sentence of no more than 79 characters:
\(C_{++}\)is challenging but fun! Enter
The sentence you entered is:
C++ is challenging but fun!

\subsection*{10.4 Library Functions for Working with C-Strings}

CONCEPT: The C++ library has numerous functions for handling C-strings. These functions perform various tests and manipulations, and require the <cstring> header file be included.

\section*{The strlen Function}

Because C-strings are stored in arrays, working with them is quite different from working with string objects. Fortunately, the C++ library provides many functions for manipulating and testing C-strings. These functions all require the <cstring> header file to be included, as shown here:
```

\#include <cstring>

```

For instance, the following code segment uses the strlen function to determine the length of the string stored in the name array:
```

char name[] = "Thomas Edison";
int length;
length = strlen(name);

```

The strlen function accepts a pointer to a C-string as its argument. It returns the length of the string, which is the number of characters up to, but not including, the null terminator. As a result, the variable length will have the number 13 stored in it. The length of a string isn't to be confused with the size of the array holding it. Remember, the only information being passed to strlen is the beginning address of a C-string. It doesn't know where the array ends, so it looks for the null terminator to indicate the end of the string.

When using a C-string-handling function, you must pass one or more C-strings as arguments. This means passing the address of the C-string, which may be accomplished by using any of the following as arguments:
- The name of the array holding the C -string
- A pointer variable that holds the address of the C-string
- A literal string

Anytime a literal string is used as an argument to a function, the address of the literal string is passed. Here is an example of the strlen function being used with such an argument:
```

length = strlen("Thomas Edison");

```

\section*{The strcat Function}

The strcat function accepts two pointers to C-strings as its arguments. The function concatenates, or appends one string to another. The following code shows an example of its use:
```

const int SIZE = 13;
char string1[SIZE] = "Hello ";
char string2[] = "World!";
cout << string1 << endl;
cout << string2 << endl;
strcat(string1, string2);
cout << string1 << endl;

```

These statements will cause the following output:
```

Hello
World!
Hello World!

```

The strcat function copies the contents of string2 to the end of string1. In this example, string1 contains the string "Hello " before the call to strcat. After the call, it contains the string "Hello World!". Figure 10-2 shows the contents of both arrays before and after the function call.

Figure 10-2 Using strcat
Before the call to strcat (string1, string2):
string1
\begin{tabular}{|c|c|c|c|c|c|c|c|c|c|c|c|c|}
\hline\(H\) & \(e\) & I & I & o & & 10 & & & & & & \\
\hline
\end{tabular}
string2
\begin{tabular}{|c|c|c|c|c|c|c|}
\hline W & o & r & l & d & ! & 10 \\
\hline
\end{tabular}

After the call to strcat (string1, string2) :
string1
\begin{tabular}{|c|c|c|c|c|c|c|c|c|c|c|c|c|}
\hline H & e & I & I & o & & W & o & r & I & d & ! & 10 \\
\hline
\end{tabular}
string2
\begin{tabular}{|c|c|c|c|c|c|c|}
\hline w & o & r & l & d & l & 10 \\
\hline
\end{tabular}

Notice the last character in string1 (before the null terminator) is a space. The strcat function doesn't insert a space, so it's the programmer's responsibility to make sure one is already there, if needed. It's also the programmer's responsibility to make sure the array holding string1 is large enough to hold string1 plus string2 plus a null terminator.

Here is a program segment that uses the sizeof operator to test an array's size before strcat is called:
```

if (sizeof(string1) >= (strlen(string1) + strlen(string2) + 1))
strcat(string1, string2);
else
cout << "String1 is not large enough for both strings.\n";

```

WARNING! If the array holding the first string isn't large enough to hold both strings, strcat will overflow the boundaries of the array.

\section*{The strcpy Function}

Recall from Chapter 7 that one array cannot be assigned to another with the \(=\) operator Each individual element must be assigned, usually inside a loop. The strcpy function can be used to copy one string to another. Here is an example of its use:
```

const int SIZE = 13;
char name[SIZE];
strcpy(name, "Albert Einstein");

```

The strcpy function's two arguments are C-string addresses. The contents of the second argument are copied to the memory location specified by the first argument, including the null terminator. (The first argument usually references an array.) In this example, the strcpy function will copy the string "Albert Einstein" to the name array.

If anything is already stored in the location referenced by the first argument, it is overwritten, as shown in the following program segment:
```

const int SIZE = 10;
char string1[SIZE] = "He1lo", string2[SIZE] = "Wor1d!";
cout << string1 << endl;
cout << string2 << endl;
strcpy(string1, string2);
cout << string1 << endl;
cout << string2 << endl;

```

Here is the output:
Hello
World!
World!
World!

WARNING! Being true to C++'s nature, strcpy performs no bounds checking. The array specified by the first argument will be overflowed if it isn't large enough to hold the string specified by the second argument.

\section*{The strncat and strncpy Functions}

Because the strcat and strcpy functions can potentially overwrite the bounds of an array, they make it possible to write unsafe code. As an alternative, you should use strncat and strncpy whenever possible.

The strncat functions works like strcat, except it takes a third argument specifying the maximum number of characters from the second string to append to the first. Here is an example call to strncat:
```

strncat(string1, string2, 10);

```

When this statement executes, strncat will append no more than 10 characters from string2 to string1. The following code shows an example of calculating the maximum number of characters that can be appended to an array:
```

int maxChars;
const int SIZE_1 = 17;
const int SIZE_2 = 18;
char string1[SIZE_1] = "We1come ";
char string2[SIZE_2] = "to North Carolina";
cout << string1 << endl;
cout << string2 << endl;
maxChars = sizeof(string1) - (strlen(string1) + 1);
strncat(string1, string2, maxChars);
cout << string1 << endl;

```

The statement in line 10 calculates the number of empty elements in string1. It does this by subtracting the length of the string stored in the array plus 1 for the null terminator. This code will cause the following output:
```

Welcome
to North Carolina
Welcome to North

```

The strncpy function allows you to copy a specified number of characters from a string to a destination. Calling strncpy is similar to calling strcpy, except you pass a third argument specifying the maximum number of characters from the second string to copy to the first. Here is an example call to strncpy:
```

strncpy(string1, string2, 5);

```

When this statement executes, strncpy will copy no more than five characters from string2 to string1. However, if the specified number of characters is less than or equal to the length of string2, a null terminator is not appended to string1. If the specified number of characters is greater than the length of string2, then string1 is padded with null terminators, up to the specified number of characters. The following code shows an example using the strncpy function:
```

int maxChars;
const int SIZE = 11;
char string1[SIZE];
char string2[] = "I love C++ programming!";

```
```

7 maxChars = sizeof(string1) - 1;
8 strncpy(string1, string2, maxChars);
9 // Put the null terminator at the end.
10 string1[maxChars] = '\0';
11 cout << string1 << endl;

```

Notice a statement was written in line 10 to put the null terminator at the end of string1. This is because maxChars was less than the length of string2, and strncpy did not automatically place a null terminator there.

\section*{The strstr Function}

The strstr function searches for a string inside of a string. For instance, it could be used to search for the string "seven" inside the larger string "Four score and seven years ago." The function's first argument is the string to be searched, and the second argument is the string for which to look. If the function finds the second string inside the first, it returns the address of the occurrence of the second string within the first string. Otherwise, it returns nullptr (the address 0 ). Here is an example:
```

char arr[] = "Four score and seven years ago";
char *strPtr = nullptr;
cout << arr << endl;
strPtr = strstr(arr, "seven"); // search for "seven"
cout << strPtr << endl;

```

In this code, strstr will locate the string "seven" inside the string "Four score and seven years ago." It will return the address of the first character in "seven" which will be stored in the pointer variable strPtr. If run as part of a complete program, this segment will display the following:
```

Four score and seven years ago
seven years ago

```

NOTE: The nullptr key word was introduced in \(\mathrm{C}++\) 11. If you are using a previous version of the C++ language, use the constant NULL instead.

The strstr function can be useful in any program that must locate data inside one or more strings. Program 10-6, for example, stores a list of product numbers and descriptions in an array of C-strings. It allows the user to look up a product description by entering all or part of its product number.

\section*{Program 10-6}
```

// This program uses the strstr function to search an array.
\#include <iostream>
\#include <cstring> // For strstr
using namespace std;
int main()
{
// Constants for array lengths
const int NUM_PRODS = 5; // Number of products
const int LENGTH = 27; // String length

```

char lookUp[LENGTH]; // To hold user's input

```
char *strPtr = nullptr; // To point to the found product
int index; // Loop counter
// Prompt the user for a product number.
cout << "\tProduct Database\n\n";
cout << "Enter a product number to search for: ";
cin.getline(lookUp, LENGTH);
// Search the array for a matching substring
for (index \(=0 ;\) index < NUM_PRODS; index++)
\{
    strPtr = strstr(products[index], lookUp);
    if (strPtr ! \(=\) nullptr)
            break;
\}
    // If a matching substring was found, display the product info.
    if (strPtr ! = nullptr)
        cout << products[index] << end1;
else
        cout << "No matching product was found. 1 n ";
    return 0;
\}

\section*{Program Output with Example Input Shown in Bold}

\section*{Product Database}

Enter a product to search for: CS Enter
CS109 Car Stereo

\section*{Program Output with Different Example Input Shown in Bold}

Product Database
Enter a product to search for: AB Enter
No matching product was found.

Table 10-3 summarizes the string-handling functions discussed here, as well as the strcmp function that was discussed in Chapter 4. (All the functions listed require the <cstring> header file.)

In Program 10-6, the for loop in lines 30 through 35 steps through each C-string in the array calling the following statement:
```

strPtr = strstr(prods[index], lookUp);

```

The strstr function searches the string referenced by prods [index] for the name entered by the user, which is stored in lookUp. If lookUp is found inside prods [index], the function returns its address. In that case, the following if statement causes the for loop to terminate:
```

if (strPtr != nul1ptr)
break;

```

Outside the loop, the following if el se statement in lines 38 through 41 determines whether the string entered by the user was found in the array. If not, it informs the user that no matching product was found. Otherwise, the product number and description are displayed.
```

if (strPtr == nullptr)
cout << "No matching product was found.\n";
else
cout << prods[index] << endl;

```

\section*{The strcmp Function}

Because C-strings are stored in char arrays, you cannot use the relational operators to compare two C-strings. To compare C-strings, you should use the library function strcmp. This function takes two C-strings as arguments and returns an integer that indicates how the two strings compare to each other. Here is the function's prototype:
```

int strcmp(char *string1, char *string2);

```

The function takes two C-strings as parameters (actually, pointers to C-strings) and returns an integer result. The value of the result is set accordingly:
- The result is zero if the two strings are equal on a character-by-character basis.
- The result is negative if string1 comes before string2 in alphabetical order.
- The result is positive if string1 comes after string2 in alphabetical order.

Here is an example of the use of stramp to determine if two strings are equal:
```

if (strcmp(string1, string2) == 0)
cout << "The strings are equal.\n";
else
cout << "The strings are not equal.\n";

```

Program 10-7 shows a complete example.

\section*{Program 10-7}
```

// This program tests two C-strings for equality
// using the strcmp function.
\#include <iostream>
\#include <string>
using namespace std;
int main()
{
// Two arrays for two strings.
const int LENGTH = 40;
char firstString[LENGTH], secondString[LENGTH];

```
```

13 // Read two strings.
14 cout << "Enter a string: ";
15
16
1 7
1 8
19
20
21
22
23
24
25 return 0;
26 }

```

\section*{Program Output with Example Input Shown in Bold}

Enter a string: Alfonso Enter
Enter another string: Alfonso Enter
You entered the same string twice.

The strcmp function is case sensitive when it compares strings. If the user enters "Dog" and "dog" in Program 10-7, it will report they are not the same. Most compilers provide nonstandard versions of strcmp that perform case-insensitive comparisons. For instance, some compilers provide a function named stricmp that works identically to strcmp, except the case of the characters is ignored.

Program 10-8 is a more practical example of how strcmp can be used. It asks the user to enter the part number of the MP3 player they wish to purchase. The part number contains digits, letters, and a hyphen, so it must be stored as a string. Once the user enters the part number, the program displays the price of the stereo.

\section*{Program 10-8}
```

// This program uses strcmp to compare the string entered
// by the user with the valid MP3 player part numbers.
\#include <iostream>
\#include <cstring>
\#include <iomanip>
using namespace std;
int main()
{
// Price of parts.
const double A_PRICE = 99.0,
B_PRICE = 199.0;
// Character array for part number.
const int PART_LENGTH = 9;
char partNum[PART_LENGTH];

```

\section*{Program 10-8 (continued)}

18 // Instruct the user to enter a part number.
19

\section*{Program Output with Example Input Shown in Bold}
```

The MP3 player part numbers are:
16 Gigabyte, part number S147-29A
32 Gigabyte, part number S147-29B
Enter the part number of the stereo you
wish to purchase: S147-29B Enter
The price is \$199.00

```

\section*{Using! with strcmp}

Some programmers prefer to use the logical NOT operator with strcmp when testing strings for equality. Because 0 is considered logically false, the ! operator converts that value to true. The expression !strcmp (string1, string2) returns true when both strings are the same, and false when they are different. The two following statements perform the same operation:
```

if (strcmp(firstString, secondString) == 0)
if (!strcmp(firstString, secondString))

```

\section*{Sorting Strings}

Programs are frequently written to print alphabetically sorted lists of items. For example, consider a department store computer system that keeps customers' names and addresses in a file. The names do not appear in the file alphabetically, but in the order the operator entered them. If a list were to be printed in this order, it would be very difficult to locate any specific name. The list would have to be sorted before it was printed.

Because the value returned by strcmp is based on the relative alphabetic order of the two strings being compared, it can be used in programs that sort strings. Program 10-9 asks the user to enter two names, which are then printed in alphabetic order.

\section*{Program 10-9}
```

// This program uses the return value of strcmp to
// alphabetically sort two strings entered by the user.
\#include <iostream>
\#include <string>
using namespace std;
int main()
{
// Two arrays to hold two strings.
const int NAME_LENGTH = 30;
char name1[NAME_LENGTH], name2[NAME_LENGTH];
// Read two strings.
cout << "Enter a name (last name first): ";
cin.getline(name1, NAME_LENGTH);
cout << "Enter another name: ";
cin.getline(name2, NAME_LENGTH);
// Print the two strings in alphabetical order.
cout << "Here are the names sorted alphabetically:\n";
if (strcmp(name1, name2) < 0)
cout << name1 << end1 << name2 << endl;
else if (strcmp(name1, name2) > 0)
cout << name2 << endl << name1 << endl;
else
cout << "You entered the same name twice!\n";
return 0;
}

```

\section*{Program Output with Example Input Shown in Bold}

Enter a name (last name first): Smith, Richard Enter
Enter another name: Jones, John Enter
Here are the names sorted alphabetically:
Jones, John
Smith, Richard
Table 10-3 provides a summary of the C-string-handling functions we have discussed. All of the functions listed require the <cstring> header file.

Table 10-3 Some of the C-String Functions in <cstring>
\begin{tabular}{ll}
\hline Function & Description \\
\hline strlen & \begin{tabular}{l} 
Accepts a C-string or a pointer to a C-string as an argument. Returns the length of \\
the C-string (not including the null terminator.) \\
Example Usage: len = strlen (name) ;
\end{tabular} \\
strcat & \begin{tabular}{l} 
Accepts two C-strings or pointers to two C-strings as arguments. The function \\
appends the contents of the second string to the first C-string. (The first string is \\
altered, the second string is left unchanged.) \\
Example Usage: strcat (string1, string2) ;
\end{tabular} \\
\hline
\end{tabular}

Table 10-3 (continued)
\begin{tabular}{|c|c|}
\hline Function & Description \\
\hline strcpy & Accepts two C-strings or pointers to two C-strings as arguments. The function copies the second C -string to the first C -string. The second C -string is left unchanged. Example Usage: strcpy (string1, string2); \\
\hline strncat & \begin{tabular}{l}
Accepts two C-strings or pointers to two C-strings, and an integer argument. The third argument, an integer, indicates the maximum number of characters to copy from the second C -string to the first C -string. \\
Example Usage: strncat(string1, string2, n);
\end{tabular} \\
\hline strncpy & Accepts two C-strings or pointers to two C-strings, and an integer argument. The third argument, an integer, indicates the maximum number of characters to copy from the second C -string to the first C -string. If n is less than the length of string2, the null terminator is not automatically appended to string1. If \(n\) is greater than the length of string2, string1 is padded with ' 10 ' characters. Example Usage: strncpy (string1, string2, n); \\
\hline strcmp & \begin{tabular}{l}
Accepts two C-strings or pointers to two C-strings arguments. If string1 and string2 are the same, this function returns 0 . If string 2 is alphabetically greater than string1, it returns a negative number. If string2 is alphabetically less than string1, it returns a positive number. \\
Example Usage: if (strcmp(string1, string2))
\end{tabular} \\
\hline strstr & \begin{tabular}{l}
Accepts two C-strings or pointers to two C-strings as arguments. Searches for the first occurrence of string2 in string1. If an occurrence of string2 is found, the function returns a pointer to it. Otherwise, it returns nul1ptr (address 0). \\
Example Usage: cout << strstr(string1, string2);
\end{tabular} \\
\hline
\end{tabular}

\section*{(8) Checkpoint}
10.6 Write a short description of each of the following functions:
```

strlen

```
strcat
strcpy
strncat
strncpy
strcmp
strstr
10.7 What will the following program segment display?
```

char dog[] = "Fido";
cout << strlen(dog) << endl;

```
10.8 What will the following program segment display?
```

char string1[16] = "Have a ";
char string2[9] = "nice day";
strcat(string1, string2);
cout << string1 << endl;
cout << string2 << endl;

```
10.9 Write a statement that will copy the string "Beethoven" to the array composer.
10.10 When complete, the following program skeleton will search for the string "Windy" in the array \(p l a c e\). If \(p l a c e\) contains "Windy" the program will display the message "Windy found." Otherwise, it will display "Windy not found."
```

\#include <iostream>
// include any other necessary header files
using namespace std;
int main()
{
char place[] = "The Windy City";
// Complete the program. It should search the array place
// for the string "Windy" and display the message "Windy
// found" if it finds the string. Otherwise, it should
// display the message "Windy not found."
return 0;
}

```

\subsection*{10.5 String/Numeric Conversion Functions}

CONCEPT: The C++ library provides functions for converting C-strings and string objects to numeric data types and vice versa.

There is a great difference between a number that is stored as a string, and one stored as a numeric value. The string "26792" isn't actually a number, but a series of ASCII codes representing the individual digits of the number. It uses 6 bytes of memory (including the null terminator). Because it isn't an actual number, it's not possible to perform mathematical operations with it, unless it is first converted to a numeric value.

Several functions exist in the C++ library for converting C-string representations of numbers into numeric values. Table 10-4 shows some of these. Note all of these functions require the <cstdlib> header file.

Table 10-4 C-String/Numeric Conversion Functions in <cstdlib>
\begin{tabular}{|c|c|}
\hline Function & Description \\
\hline atoi & \begin{tabular}{l}
Accepts a C-string as an argument. The function converts the C-string to an integer and returns that value. \\
Example Usage: int num = atoi ("4569") ;
\end{tabular} \\
\hline atol & \begin{tabular}{l}
Accepts a C-string as an argument. The function converts the C-string to a long integer and returns that value. \\
Example Usage: 1ong 1num = atol("500000");
\end{tabular} \\
\hline atof & \begin{tabular}{l}
Accepts a C-string as an argument. The function converts the C-string to a double and returns that value. \\
Example Usage: double fnum = atof("3.14159");
\end{tabular} \\
\hline
\end{tabular}

NOTE: If a C-string that cannot be converted to a numeric value is passed to any of the functions in Table 10-4, the function's behavior is undefined by C++. Many compilers, however, will perform the conversion process until an invalid character is encountered. For example, atoi ( " \(123 \times 5\) ") might return the integer 123. It is possible that these functions will return 0 if they cannot successfully convert their argument.

\section*{The string to Number Functions}

C++ 11 introduced several new functions that convert string objects to numeric values. Table 10-5 lists the functions. To use any of the functions in Table \(10-5\), you must \#include the <string> header file.

\section*{Table 10-5 string to Number Functions}
\begin{tabular}{ll} 
Function & Description \\
stoi (string str) & \begin{tabular}{l} 
Accepts a string argument and returns that argument's value \\
converted to an int.
\end{tabular} \\
stol (string str) & \begin{tabular}{l} 
Accepts a string argument and returns that argument's value \\
converted to a long.
\end{tabular} \\
stoul (string str) & \begin{tabular}{l} 
Accepts a string argument and returns that argument's value \\
converted to an unsigned long.
\end{tabular} \\
stoll (string str) & \begin{tabular}{l} 
Accepts a string argument and returns that argument's value \\
converted to a long long.
\end{tabular} \\
stoull(string str) & \begin{tabular}{l} 
Accepts a string argument and returns that argument's value \\
converted to an unsigned long long.
\end{tabular} \\
stof(string str) & \begin{tabular}{l} 
Accepts a string argument and returns that argument's value \\
converted to a float.
\end{tabular} \\
stod(string str) & \begin{tabular}{l} 
Accepts a string argument and returns that argument's value \\
converted to a double.
\end{tabular} \\
stold(string str) & \begin{tabular}{l} 
Accepts a string argument and returns that argument's value \\
converted to a long double.
\end{tabular} \\
\hline
\end{tabular}

NOTE: If a string that cannot be converted to a numeric value is passed to any of the functions in Table 10-5, the function will throw an invalid_argument exception. If the string argument converts to a value that is out of range for the target data type, the function will throw an out_of_range exception.

The functions shown in Table 10-5 can accept either a string object or a C-string as an argument. For example, each of the following code snippets use the stoi function to convert the string " 99 " to an int:
```

// Convert a string object to an int.
string str = "99";
int i = stoi(str);
// Convert a string literal to an int.
int i = stoi("99");

```
```

// Convert a C-String in a char array to an int.
char cstr[] = "99";
int i = stoi(cstr);

```

\section*{The to_string Function}

C++ 11 introduces a function named to_string that converts a numeric value to a string object. There are nine overloaded versions of the to_string function listed in Table 10-6. Note the to_string function requires the <string> header file to be included.

Each version of the function accepts an argument of a numeric data type and returns the value of that argument converted to a string object. Here is an example:
```

int number = 99;
string output = to_string(number);

```

Table 10-6 Overloaded Versions of the to_string Function
\begin{tabular}{|c|c|}
\hline Function & Description \\
\hline to_string(int value); & Accepts an int argument and returns that argument converted to a string object. \\
\hline to_string(long value); & Accepts a long argument and returns that argument converted to a string object. \\
\hline to_string(long long value); & Accepts a long long argument and returns that argument converted to a string object. \\
\hline to_string(unsigned value); & Accepts an unsigned argument and returns that argument converted to a string object. \\
\hline to_string(unsigned long value); & Accepts an unsigned long argument and returns that argument converted to a string object. \\
\hline to_string(unsigned long long value); & Accepts an unsigned long long argument and returns that argument converted to a string object. \\
\hline to_string(float value); & Accepts a float argument and returns that argument converted to a string object. \\
\hline to_string(double value); & Accepts a double argument and returns that argument converted to a string object. \\
\hline to_string(long double value); & Accepts a long double argument and returns that argument converted to a string object. \\
\hline
\end{tabular}

The first statement initializes the number variable (an int) to the value 99. In the second statement, the number variable is passed as an argument to the to_string function. The to_string function returns the value " 99 ", which is assigned to the output variable.
Here is another example:
```

double number = 3.14159;
cout << to_string(number) << endl;

```

The first statement initializes the number variable (a double) to the value 3.14159. In the second statement, the number variable is passed as an argument to the to_string function, and the value " 3.14159 " is returned from the function and displayed on the screen.

Now let's look at Program 10-10, which uses one of the C++ 11 string-to-number conversion functions, stoi. It allows the user to enter a series of values, or the letter \(Q\) or \(q\) to quit. The average of the numbers is then calculated and displayed.

\section*{Program 10-10}
```

// This program demonstrates the tolower and stoi functions.
\#include <iostream>
\#include <cctype> // For tolower
\#include <string>
using namespace std;
int main()
{
string input; // To hold user input
int total = 0; // Accumulator
int count = 0; // Loop counter
double average; // To hold the average of numbers
// Get the first number.
cout << "This program will average a series of numbers.\n";
cout << "Enter the first number or Q to quit: ";
getline(cin, input);
// Process the number and subsequent numbers.
while (tolower(input[0]) != 'q')
{
total += stoi(input); // Keep a running total
count++; // Count the numbers entered
// Get the next number.
cout << "Enter the next number or Q to quit: ";
getline(cin, input);
}
// If any numbers were entered, display their average.
if (count != 0)
{
average = static_cast<double>(tota1) / count;
cout << "Average: " << average << endl;
}
return 0;
}

```

\section*{Program Output with Example Input Shown in Bold}

This program will average a series of numbers.
Enter the first number or \(Q\) to quit: 1 Enter
Enter the next number or \(Q\) to quit: 2 Enter
Enter the next number or \(Q\) to quit: 3 Enter
Enter the next number or \(Q\) to quit: 4 Enter
Enter the next number or \(Q\) to quit: 5 Enter
Enter the next number or \(Q\) to quit: \(\mathbf{q}\) Enter
Average: 3

In line 20, the following while statement uses the tolower function to determine whether the first character entered by the user is " \(q\) " or " \(Q\) ".
```

while (tolower(input[0]) != 'q')

```

If the user hasn't entered ' \(Q\) ' or ' \(q\) ', the loop performs an iteration. The following statement, in line 22 , uses stoi to convert input to an integer, and adds its value to total:
```

total += stoi(input); // Keep a running total

```

The counter is updated in line 23 , then the user is asked for the next number. When all the numbers are entered, the user terminates the loop by entering ' \(Q\) ' or ' \(q\) '. If one or more numbers are entered, their average is displayed.

The string-to-numeric conversion functions can also help with a common input problem. Recall from Chapter 3 that using cin >> then calling cin.get causes problems because the >> operator leaves the newline character in the keyboard buffer. When the cin.get function executes, the first character it sees in the keyboard buffer is the newline character, so it reads no further.

The same problem exists when a program uses cin >> then calls getiine to read a line of input. For example, look at the following code. (Assume idNumber is an int and name is a string object.)
```

// Get the user's ID number.
cout << "What is your ID number? ";
cin >> idNumber;
// Get the user's name.
cout << "What is your name? ";
get1ine(cin, name);

```

Let's say the user enters 25 and presses Enter when the cin >> statement in line 3 executes. The value 25 will be stored in idNumber, and the newline character will be left in the keyboard buffer. When the getline function is called in line 7 , the first character it sees in the keyboard buffer is the newline character, so it reads no further. It will appear that the statement in line 7 was skipped.

One work-around that we have used in this book is to call cin.ignore to skip over the newline character just before calling get 1 ine. Another approach is to use get 1 ine to read all of a program's input, including numbers. When numeric input is needed, it is read into a string object as a string then converted to the appropriate numeric data type. Because you aren't mixing cin \(\gg\) with getline, the problem of the remaining newline character doesn't exist. Program 10-11 shows an example.

\section*{Program 10-11}
```

// This program demonstrates how the getline function can
// be used for all of a program's input.
\#include <iostream>
\#include <string>
\#include <iomanip>
using namespace std;

```

\section*{Program 10-11 (continued)}
```

int main()
{
string input; // To hold a line of input
string name; // To hold a name
int idNumber; // To hold an ID number.
int age; // To hold an age
double income; // To hold income
// Get the user's ID number.
cout << "What is your ID number? ";
getline(cin, input); // Read as a string
idNumber = stoi(input); // Convert to int
// Get the user's name. No conversion necessary.
cout << "What is your name? ";
getline(cin, name);
// Get the user's age.
cout << "How old are you? ";
getline(cin, input); // Read as a string
age = stoi(input); // Convert to int
// Get the user's income.
cout << "What is your annual income? ";
getline(cin, input); // Read as a string
income = stod(input); // Convert to double
// Show the resulting data.
cout << setprecision(2) << fixed << showpoint;
cout << "Your name is " << name
<<", you are " << age
<< " years old,\nand you make \$"
<< income << " per year.\n";
return 0;
}

```

\section*{Program Output with Example Input Shown in Bold}

What is your ID number? 1234 Enter
What is your name? Janice Smith Enter
How old are you? 25 Enter
What is your annual income? 60000 Enter
Your name is Janice Smith, you are 25 years old,
and you make \(\$ 60000.00\) per year.

\section*{Checkpoint}
10.11 Write a short description of each of the following functions:
\begin{tabular}{ll} 
atoi & stoi \\
atol & stol \\
atof & stof \\
itoa & stod
\end{tabular}
10.12 Write a statement that will convert the string " 10 " to an integer and store the result in the variable num.
10.13 Write a statement that will convert the string " 100000 " to a long and store the result in the variable num.
10.14 Write a statement that will convert the string " 7.2389 " to a double and store the result in the variable num.
10.15 Write a statement that will convert the integer 127 to a string, and assign the result to a string object named str.

\subsection*{10.6 Focus on Software Engineering: Writing Your Own C-String-Handling Functions}

VideoNote
Writing a C-StringHandling Function

CONCEPT: You can design your own specialized functions for manipulating strings.

\section*{Program 10-12}
```

// This program uses a function to copy a C-string into an array.
\#include <iostream>
using namespace std;
void stringCopy(char [], char []); // Function prototype
int main()
{
const int LENGTH = 30; // Size of the arrays
char first[LENGTH]; // To hold the user's input
char second[LENGTH]; // To hold the copy
// Get a string from the user and store in first.
cout << "Enter a string with no more than "
<< (LENGTH - 1) << " characters:\n";
cin.getline(first, LENGTH);

```

\section*{Program 10-12 (continued)}
```

    // Copy the contents of first to second.
    stringCopy(first, second);
    // Display the copy.
    cout << "The string you entered is:\n" << second << endl;
    return 0;
    }
/|*************************************************************
// Definition of the stringCopy function.
// This function copies the C-string in string1 to string2.*
//************************************************************
void stringCopy(char string1[], char string2[])
{
int index = 0; // Loop counter
// Step through string1, copying each element to
// string2. Stop when the nul1 character is encountered.
while (string1[index] != '\0')
{
string2[index] = string1[index];
index++;
}
// Place a null character in string2.
string2[index] = '\0';
}

```

\section*{Program Output with Example Input Shown in Bold}

Enter a string with no more than 29 characters:
Thank goodness it's Friday! Enter
The string you entered is:
Thank goodness it's Friday!
Notice the function stringCopy does not accept an argument indicating the size of the arrays. It simply copies the characters from string1 into string2 until it encounters a null terminator in string1. When the null terminator is found, the loop has reached the end of the C-string. The last statement in the function assigns a null terminator (the ' 10 ' character) to the end of string2, so it is properly terminated.

WARNING! Because the stringCopy function doesn't know the size of the second array, it's the programmer's responsibility to make sure the second array is large enough to hold the string in the first array.

Program 10-13 uses another C-string-handling function: nameS1ice. The program asks the user to enter his or her first and last names, separated by a space. The function searches the string for the space and replaces it with a null terminator. In effect, this "cuts" the last name off of the string.

\section*{Program 10-13}
```

// This program uses the function nameSlice to cut the last
// name off of a string that contains the user's first and
// last names.
\#include <iostream>
using namespace std;
void nameSlice(char []); // Function prototype
int main()
{
const int SIZE = 41; // Array size
char name[SIZE]; // To hold the user's name
cout << "Enter your first and last names, separated ";
cout << "by a space:\n";
cin.getline(name, SIZE);
nameS1ice(name);
cout << "Your first name is: " << name << endl;
return 0;
}
//*******************************************************************
// character array as its argument. It scans the array looking *
// for a space. When it finds one, it replaces it with a null *
// terminator.
/l***************************************************************
void nameSlice(char userName[])
{
int count = 0; // Loop counter
// Locate the first space, or the null terminator if there
// are no spaces.
while (userName[count] != ' ' \&\& userName[count] != '\0')
count++;
// If a space was found, replace it with a null terminator.
if (userName[count] == ' ')
userName[count] = '\0';
}

```

\section*{Program Output with Example Input Shown in Bold}

Enter your first and last names, separated by a space:
Jimmy Jones Enter
Your first name is: Jimmy

The following loop in lines 35 and 36 starts at the first character in the array and scans the string searching for either a space or a null terminator:
```

while (userName[count] != ' ' \&\& userName[count] != '\0')
count++;

```

If the character in userName [count] isn't a space or the null terminator, count is incremented, and the next character is examined. With the example input "Jimmy Jones," the loop finds the space separating "Jimmy" and "Jones" at userName[5]. When the loop stops, count is set to 5 . This is illustrated in Figure 10-3.

\section*{Figure 10-3 Scanning for a space in a string}

The loop stops when count reaches 5 because userName [5] contains a space.
\begin{tabular}{|c|c|c|c|c|c|c|c|c|c|c|c|c|}
\(\downarrow\) \\
\hline & i & m & m & y & & J & 0 & n & e & s & 10 & \\
\hline 0 & 1 & 2 & 3 & 4 & 5 & 6 & 7 & 8 & 9 & 10 & 11 & 12 \\
\hline
\end{tabular}

Subscripts

NOTE: The loop will also stop if it encounters a null terminator. This is so it will not go beyond the boundary of the array if the user didn't enter a space.

Once the loop has finished, userName [count] will either contain a space or a null terminator. If it contains a space, the following if statement (in lines 39 and 40) replaces it with a null terminator:
```

if (userName[count] == ' ')
userName[count] = '\0';

```

This is illustrated in Figure 10-4.

\section*{Figure 10-4 Replacing a space with a null terminator}

The space is replaced with a null terminator. This now becomes the end of the string.
\begin{tabular}{|c|c|c|c|c|c|c|c|c|c|c|c|c|}
\hline\(\downarrow\) & i & m & m & y & 10 & J & o & n & e & s & 10 & \\
\hline \begin{tabular}{cc}
0 & 1
\end{tabular} & 2 & 3 & 4 & 5 & 6 & 7 & 8 & 9 & 10 & 11 & 12 \\
Subscripts
\end{tabular}

The new null terminator now becomes the end of the string.

\section*{Using Pointers to Pass C-String Arguments}

Pointers are extremely useful for writing functions that process C-strings. If the starting address of a string is passed into a pointer parameter variable, it can be assumed that all the characters, from that address up to the byte that holds the null terminator, are part of the string. (It isn't necessary to know the length of the array that holds the string.)
Program 10-14 demonstrates a function, countChars, that uses a pointer to count the number of times a specific character appears in a C -string.

\section*{Program 10-14}
// This program demonstrates a function, countChars, that counts // the number of times a specific character appears in a string. \#include <iostream>
```

using namespace std;
int countChars(char *, char); // Function prototype
int main()
{
const int SIZE = 51; // Array size
char userString[SIZE]; // To hold a string
char letter; // The character to count
// Get a string from the user.
cout << "Enter a string (up to 50 characters): ";
cin.getline(userString, SIZE);
// Choose a character whose occurrences within the string will be counted.
cout << "Enter a character and I will tell you how many\n";
cout << "times it appears in the string: ";
cin >> letter;
// Display the number of times the character appears.
cout << letter << " appears ";
cout << countChars(userString, letter) << " times.\n";
return 0;
}
//******************************************************************
// Definition of countChars. The parameter strPtr is a pointer
// that points to a string. The parameter Ch is a character that
// the function searches for in the string. The function returns
// the number of times the character appears in the string.
//*********************************************************************
int countChars(char *strPtr, char ch)
{
int times = 0; // Number of times ch appears in the string
// Step through the string counting occurrences of ch.
while (*strPtr != '\0')
{
if (*strPtr == ch) // If the current character equals ch...
times++; // ... increment the counter
strPtr++; // Go to the next char in the string.
}
return times;
}

```

\section*{Program Output with Example Input Shown in Bold}

Enter a string (up to 50 characters) : Starting Out with C++ Enter
Enter a character and I will tell you how many
times it appears in the string: \(\mathbf{t}\) Enter
\(t\) appears 4 times.

In the function countChars, strPtr points to the C-string that is to be searched, and ch contains the character for which to look. The while loop in lines 41 through 46 repeats as long as the character that strPtr points to is not the null terminator:
```

while (*strPtr != '\0')

```

Inside the loop, the if statement in line 43 compares the character that strPtr points to with the character in ch:
```

if (*strPtr == ch)

```

If the two are equal, the variable times is incremented in line 44 . (times keeps a running total of the number of times the character appears.) The last statement in the loop is
```

strPtr++;

```

This statement increments the address in strPtr. This causes strPtr to point to the next character in the string. Then, the loop starts over. When strPtr finally reaches the null terminator, the loop terminates, and the function returns the value in times.
For another example, see the String Manipulation Case Study, available for download from the Computer Science Portal at www.pearsonglobaleditions.com/gaddis.

\section*{Checkpoint}
10.16 What is the output of the following program?
```

\#include <iostream>
using namespace std;
// Function Prototype
void mess(char []);
int main()
{
char stuff[] = "Tom Talbert Tried Trains";
cout << stuff << endl;
mess(stuff);
cout << stuff << endl;
return 0;
}
// Definition of function mess
void mess(char str[])
{
int step = 0;
while (str[step] != '\0')
{
if (str[step] == 'T')
str[step] = 'D';
step++;
}
}

```

\subsection*{10.7 More about the C++ string Class \\ CONCEPT: Standard C++ provides a special data type for storing and working with strings.}

The string class is an abstract data type. This means it is not a built-in, primitive data type like int or char. Instead, it is a programmer-defined data type that accompanies the \(\mathrm{C}++\) language. It provides many capabilities that make storing and working with strings easy and intuitive.

\section*{Using the string Class}

The first step in using the string class is to \#include the <string> header file. This is accomplished with the following preprocessor directive:
```

\#include <string>

```

Now you are ready to define a string object. Defining a string object is similar to defining a variable of a primitive type. For example, the following statement defines a string object named movieTitle:
```

string movieTitle;

```

You assign a string value to the movieTitle object with the assignment operator, as shown in the following statement:
```

movieTitle = "Wheels of Fury";

```

The contents of movieTitle are displayed on the screen with the cout object, as shown in the next statement:
```

cout << "My favorite movie is " << movieTitle << endl;

```

Program 10-15 is a complete program that demonstrates the statements shown above.

\section*{Program 10-15}
```

// This program demonstrates the string class.
\#include <iostream>
\#include <string> // Required for the string class.
using namespace std;
int main()
{
string movieTitle;
movieTitle = "Wheels of Fury";
cout << "My favorite movie is " << movieTitle << endl;
return 0;
}

```

\section*{Program Output}

My favorite movie is Wheels of Fury

As you can see, working with string objects is similar to working with variables of other types. For example, Program 10-16 demonstrates how you can use cin to read a value from the keyboard into a string object.

\section*{Program 10-16}
```

// This program demonstrates how cin can read a string into
// a string class object.
\#include <iostream>
\#include <string>
using namespace std;
int main()
{
string name;
cout << "What is your name? ";
cin >> name;
cout << "Good morning " << name << endl;
return 0;
}

```

\section*{Program Output with Example Input Shown in Bold}
```

What is your name? Peggy Enter
Good morning Peggy

```

\section*{Reading a Line of Input into a string Object}

If you want to read a line of input (with spaces) into a string object, use the getline() function. Here is an example:
```

string name;
cout << "What is your name? ";
getline(cin, name);

```

The getline() function's first argument is the name of a stream object from which you wish to read the input. The function call above passes the cin object to getline(), so the function reads a line of input from the keyboard. The second argument is the name of a string object. This is where getline() stores the input that it reads.

\section*{Comparing and Sorting string Objects}

There is no need to use a function such as stromp to compare string objects. You may use the \(<,>,<=,>=,==\), and != relational operators. For example, assume the following definitions exist in a program:
```

string set1 = "ABC";
string set2 = "XYZ";

```

The object set1 is considered less than the object set2 because the characters "ABC" alphabetically precede the characters "XYZ." So, the following if statement will cause the message "set1 is less than set2" to be displayed on the screen:
```

if (set1 < set2)
cout << "set1 is less than set2.\n";

```

Relational operators perform comparisons on string objects in a fashion similar to the way the strcmp function compares C -strings. One by one, each character in the first operand is compared with the character in the corresponding position in the second operand. If all the characters in both strings match, the two strings are equal. Other relationships can be determined if two characters in corresponding positions do not match. The first operand is less than the second operand if the mismatched character in the first operand is less than its counterpart in the second operand. Likewise, the first operand is greater than the second operand if the mismatched character in the first operand is greater than its counterpart in the second operand.
For example, assume a program has the following definitions:
```

string name1 = "Mary";
string name2 = "Mark";

```

The value in name1, "Mary," is greater than the value in name2, "Mark." This is because the " \(y\) " in "Mary" has a greater ASCII value than the " \(k\) " in "Mark."
string objects can also be compared to C-strings with relational operators. Assuming str is a string object, all of the following are valid relational expressions:
```

str > "Joseph"
"Kimberly" < str
str == "William"

```

Program 10-17 demonstrates string objects and relational operators.

\section*{Program 10-17}
```

// This program uses the == operator to compare a string entered
// by the user with the valid part numbers.
\#include <iostream>
\#include <iomanip>
\#include <string>
using namespace std;
int main()
{
const double APRICE = 249.0; // Price for part A
const double BPRICE = 199.0; // Price for part B
string partNum; // Part mumber
cout << "The headphone part numbers are:\n";
cout << "\tNoise canceling, part number S147-29A\n";
cout << "\tWireless, part number S147-29B\n";
cout << "Enter the part number of the desired headphones: ";
cin >> partNum;
cout << fixed << showpoint << setprecision(2);
if (partNum == "S147-29A")
cout << "The price is \$" << APRICE << endl;
else if (partNum == "S147-29B")
cout << "The price is \$" << BPRICE << endl;
else
cout << partNum << " is not a valid part number.\n";

```

\section*{Program 10-17 (continued)}
```

27 return 0;
28 }

```

\section*{Program Output with Example Input Shown in Bold}

The headphone part numbers are:
Noise canceling, part number S147-29A
Wireless, part number S147-29B
Enter the part number of the desired headphones: S147-29B Enter
The price is \(\$ 199.00\)
You may also use relational operators to sort string objects. Program 10-18 demonstrates this.

\section*{Program 10-18}
```

// This program uses relational operators to alphabetically
// sort two strings entered by the user.
\#include <iostream>
\#include <string>
using namespace std;
int main ()
{
string name1, name2;
// Get a name.
cout << "Enter a name (last name first): ";
getline(cin, name1);
// Get another name.
cout << "Enter another name: ";
getline(cin, name2);
// Display them in alphabetical order.
cout << "Here are the names sorted alphabetically:\n";
if (name1 < name2)
cout << name1 << end1 << name2 << end1;
else if (name1 > name2)
cout << name2 << end1 << name1 << endl;
else
cout << "You entered the same name twice!\n";
return 0;
}

```

\section*{Program Output with Example Input Shown in Bold}

Enter a name (last name first): Smith, Richard Enter
Enter another name: Jones, John Enter
Here are the names sorted alphabetically:
Jones, John
Smith, Richard

\section*{Other Ways to Define string Objects}

There are a variety of ways to initialize a string object when you define it. Table 10-7 shows several example definitions and describes each. Program 10-19 demonstrates a string object initialized with the string "William Smith."

\section*{Program 10-19}
```

// This program initializes a string object.
\#include <iostream>
\#include <string>
using namespace std;
int main()
{
string greeting;
string name("William Smith");
greeting = "Hello ";
cout << greeting << name << endl;
return 0;
}

```

\section*{Program Output}
```

Hello William Smith

```

Table 10-7 Examples of string Object Definitions
\begin{tabular}{|c|c|}
\hline Definition & Description \\
\hline string address; & Defines an empty string object named address. \\
\hline string name("William Smith"); & Defines a string object named name, initialized with "William Smith." \\
\hline string person1(person2) ; & Defines a string object named person1, which is a copy of person2. person2 may be either a string object or character array. \\
\hline string str1(str2, 5) ; & Defines a string object named str1, which is initialized to the first five characters in the character array str2. \\
\hline string lineFull('z', 10) ; & Defines a string object named 1 ineFull initialized with 10 'z' characters. \\
\hline \[
\begin{aligned}
& \text { string firstName(fullName, } \\
& \qquad 0,7) ;
\end{aligned}
\] & Defines a string object named firstName, initialized with a substring of the string fullName. The substring is seven characters long, beginning at position 0 . \\
\hline
\end{tabular}

Notice in Program 10-19 the use of the = operator to assign a value to the string object (line 11). The string class supports several operators, which are described in Table 10-8.

Table 10-8 string Class Operators
\begin{tabular}{ll}
\hline Supported Operator & Description \\
\hline\(\gg\) & \begin{tabular}{l} 
Extracts characters from a stream and inserts them into the string. \\
Characters are copied until a whitespace or the end of the string is \\
encountered.
\end{tabular} \\
\(><\) & \begin{tabular}{l} 
Inserts the string into a stream.
\end{tabular} \\
\(=\) & Assigns the string on the right to the string object on the left. \\
\(+=\) & Appends a copy of the string on the right to the string object on the left. \\
\(+\quad\) & \begin{tabular}{l} 
Returns a string that is the concatenation of the two string operands. \\
Implements array-subscript notation, as in name [x]. A reference to the \\
character in the x position is returned.
\end{tabular} \\
Relational Operators & Each of the relational operators is implemented:
\end{tabular}

Program 10-20 demonstrates some of the string operators.

\section*{Program 10-20}
```

// This program demonstrates the C++ string class.
\#include <iostream>
\#include <string>
using namespace std;
int main ()
{
// Define three string objects.
string str1, str2, str3;
// Assign values to all three.
str1 = "ABC";
str2 = "DEF";
str3 = str1 + str2;
// Display all three.
cout << str1 << endl;
cout << str2 << endl;
cout << str3 << endl;
// Concatenate a string onto str3 and display it.
str3 += "GHI";
cout << str3 << endl;
return 0;
}

```

\section*{Program Output}

ABC
DEF
ABCDEF
ABCDEFGHI

\section*{Using string Class Member Functions}

The string class also has member functions. For example, the length member function returns the length of the string stored in the object. The value is returned as an unsigned integer.

Assume the following string object definition exists in a program:
```

string town = "Charleston";

```

The following statement in the same program would assign the value 10 to the variable x .
```

x = town.length();

```

Program 10-21 further demonstrates the length member function.

\section*{Program 10-21}
```

// This program demonstrates a string
// object's length member function.
\#include <iostream>
\#include <string>
using namespace std;
int main ()
{
string town;
cout << "Where do you live? ";
cin >> town;
cout << "Your town's name has " << town.length() ;
cout << " characters\n";
return 0;
}

```

\section*{Program Output with Example Input Shown in Bold}

Where do you live? Jacksonville Enter
Your town's name has 12 characters
The size function also returns the length of the string. It is demonstrated in the for loop in Program 10-22.

\section*{Program 10-22}
```

// This program demonstrates the C++ string class.
\#include <iostream>
\#include <string>
using namespace std;
int main()
{
// Define three string objects.
string str1, str2, str3;
11 // Assign values to all three.

```
10

\section*{Program 10-22 (continued)}
```

12 str1 = "ABC";
13 str2 = "DEF";
14
15
16
17
18
19
20
21
22 // Compare str1 with str2.
23 if (str1 < str2)
24
25
26
27
str3 = str1 + str2;
// Use subscripts to display str3 one character
// at a time.
for (int x = 0; x < str3.size(); x++)
cout << str3[x];
cout << endl;
cout << "str1 is less than str2\n";
else
cout << "str1 is not less than str2\n";
return 0;
}

```

\section*{Program Output}

ABCDEF
str1 is less than str2
Table 10-9 lists many of the string class member functions and their overloaded variations. In the examples, assume mystring is the name of a string object.

\section*{Table 10-9 string Class Member Functions}
\begin{tabular}{|c|c|}
\hline Member Function Example & Description \\
\hline mystring.append(n, 'z') & Appends \(n\) copies of ' z ' to mystring. \\
\hline mystring.append(str) & Appends str to mystring. str can be a string object or character array. \\
\hline mystring.append(str, n) & The first n characters of the character array str are appended to mystring. \\
\hline mystring.append(str, x, n) & n number of characters from str, starting at position \(x\), are appended to mystring. If mystring is too small, the function will copy as many characters as possible. \\
\hline mystring.assign(n, 'z') & Assigns \(n\) copies of ' \(z\) ' to mystring. \\
\hline mystring.assign(str) & Assigns str to mystring. str can be a string object or character array. \\
\hline mystring.assign(str, n) & The first n characters of the character array str are assigned to mystring. \\
\hline mystring.assign(str, \(\mathrm{x}, \mathrm{n}\) ) & n number of characters from str, starting at position \(x\), are assigned to mystring. If mystring is too small, the function will copy as many characters as possible. \\
\hline mystring.at(x) & Returns the character at position \(x\) in the string. \\
\hline mystring.back() & Returns the last character in the string. (This member function was introduced in \(\mathrm{C}++11\).) \\
\hline
\end{tabular}

Table 10-9 (continued)
\begin{tabular}{|c|c|}
\hline Member Function Example & Description \\
\hline mystring.begin() & Returns an iterator pointing to the first character in the string. (For more information on iterators, see Chapter 16.) \\
\hline mystring.c_str() & Converts the contents of mystring to a C-string, and returns a pointer to the C -string. \\
\hline mystring.capacity() & Returns the size of the storage allocated for the string. \\
\hline mystring.clear() & Clears the string by deleting all the characters stored in it. \\
\hline mystring.compare(str) & Performs a comparison like the strcmp function (see Chapter 4), with the same return values. str can be a string object or a character array. \\
\hline mystring.compare(x, n, str) & Compares mystring and str, starting at position \(x\), and continuing for \(n\) characters. The return value is like strcmp. str can be a string object or character array. \\
\hline mystring.copy(str, x, n) & Copies the character array str to mystring, beginning at position \(x\), for \(n\) characters. If mystring is too small, the function will copy as many characters as possible. \\
\hline mystring.empty() & Returns true if mystring is empty. \\
\hline mystring.end() & Returns an iterator pointing to the last character of the string in mystring. (For more information on iterators, see Chapter 17.) \\
\hline mystring.erase(x, n ) & Erases \(n\) characters from mystring, beginning at position \(x\). \\
\hline mystring.find(str, x) & Returns the first position at or beyond position x where the string str is found in mystring. str may be either a string object or a character array. \\
\hline mystring.find('z', x) & Returns the first position at or beyond position x where ' \(z\) ' is found in mystring. If ' \(z\) ' is not found, the function returns the special value string::npos. \\
\hline mystring.front() & Returns the first character in the string. (This member function was introduced in \(\mathrm{C}++11\).) \\
\hline mystring.insert(x, \(\left.\mathrm{n}, \mathrm{l} \mathrm{z}^{\prime}\right)\) & Inserts 'z' z times into mystring at position x . \\
\hline mystring.insert(x, str) & Inserts a copy of str into mystring, beginning at position x . str may be either a string object or a character array. \\
\hline mystring.1ength() & Returns the length of the string in mystring. \\
\hline mystring.replace(x, n , str) & Replaces the \(n\) characters in mystring beginning at position \(x\) with the characters in string object str. \\
\hline mystring.resize(n, 'z') & Changes the size of the allocation in mystring to \(n\). If \(n\) is less than the current size of the string, the string is truncated to n characters. If n is greater, the string is expanded and ' z ' is appended at the end enough times to fill the new spaces. \\
\hline mystring.size() & Returns the length of the string in mystring. \\
\hline mystring.substr(x, n) & Returns a copy of a substring. The substring is n characters long and begins at position \(x\) of mystring. \\
\hline mystring.swap(str) & Swaps the contents of mystring with str. \\
\hline
\end{tabular}

\section*{In the Spotlight:}

\section*{String Tokenizing}

Sometimes a string will contain a series of words or other items of data separated by spaces or other characters. For example, look at the following string:
"peach raspberry strawberry vanilla"
This string contains the following four items of data: peach, raspberry, strawberry, and vanilla. In programming terms, items such as these are known as tokens. Notice a space appears between the items. The character that separates tokens is known as a delimiter. Here is another example:
\[
" 17 ; 92 ; 81 ; 12 ; 46 ; 5 "
\]

This string contains the following tokens: \(17,92,81,12,46\), and 5 . Notice a semicolon appears between each item. In this example, the semicolon is used as a delimiter. Some programming problems require you to read a string that contains a list of items then extract all of the tokens from the string for processing. For example, look at the following string that contains a date:
\[
\text { " } 3-22-2018 \text { " }
\]

The tokens in this string are 3,22 , and 2018 , and the delimiter is the hyphen character. Perhaps a program needs to extract the month, day, and year from such a string. Another example is an operating system pathname, such as the following:
```

/home/rsullivan/data

```

The tokens in this string are home, rsullivan, and data, and the delimiter is the ' \(/\) ' character. Perhaps a program needs to extract all of the directory names from such a pathname. The process of breaking a string into tokens is known as tokenizing, or splitting a string.
The following function, spl 1 it , shows an example of how we can split a string into tokens. The function has three parameters:
- s-the string that we want to split into tokens
- delim-the character that is used as a delimiter
- tokens-a vector that will hold the tokens once they are extracted
```

void split(const string\& s, char delim, vector<string>\& tokens)
{
int tokenStart = 0; // Starting position of the next token
// Find the first occurrence of the delimiter.
int delimPosition = s.find(delim);
// While we haven't run out of delimiters...
while (delimPosition != string::npos)
{
// Extract the token.
string tok = s.substr(tokenStart, delimPosition - tokenStart);
// Push the token onto the tokens vector.
tokens.push_back(tok);

```

Let's take a closer look at the code:
- The tokenStart variable defined in line 3 will be used to hold the starting position of the next token. This variable is initialized with 0 , assuming the first token starts at position 0 .
- In line 6, we call the s.find() function, passing delim as an argument. The function will return the position of the first occurrence of delimins. That value is assigned to the delimPosition variable. Note if the find() member function does not find the specified delimiter, it will return the special constant string::npos (which is defined as -1 ).
- The while loop that begins in line 9 iterates as long as delimPosition is not equal to string: :npos.
- Inside the while loop, line 12 extracts the substring beginning at tokenStart, and continuing up to the delimiter. The substring, which is a token, is assigned to the tok object.
- In line 15 , we push the tok object to the back of the tokens vector.
- Now we are ready to find the next token. Line 18 increments delimPosition, and line 21 sets tokenStart to the same value as delimPosition.
- Line 24 calls the s.find() function, passing delim and delimPosition as arguments. The function will return the position of the next occurrence of delim, appearing at or after delimPosition. That value is assigned to the delimPosition variable. If the specified delimiter is not found, the find() member function will return the constant string: :npos. When that happens in this statement, it means we are processing the last token in the string.
- The if statement that starts in line 27 determines whether delimPosition is equal to string: : npos. As previously stated, if this is true, it means we are processing the last token. If that is the case, line 30 extracts the token and assigns it to tok, and line 33 pushes tok to the back of the tokens vector.

Program 10-23 demonstrates the split function.

\section*{Program 10-23}
```

\#include <iostream>
\#include <string>
\#include <vector>
using namespace std;
// Function prototype
void split(const string\&, char, vector<string>\&);
int main()
{
// Strings to tokenize
string str1 = "one two three four";
string str2 = "10:20:30:40:50";
string str3 = "a/b/c/d/e/f";
// vector to hold the tokens.
vector<string> tokens;
// Tokenize str1, using ' ' as the delimiter.
split(str1, ' ', tokens);
for (auto e : tokens)
cout << e << " ";
cout << endl;
tokens.clear();
// Tokenize str2, using ':' as the delimiter.
split(str2, ':', tokens);
for (auto e : tokens)
cout << e << " ";
cout << endl;
tokens.clear();
// Tokenize str3, using '/' as the delimiter.
sp1it(str3, '/', tokens);
for (auto e : tokens)
cout << e << " ";
cout << endl;
return 0;
}
The split function is not shown bere.

```

\section*{Program Output}
one two three four
\(\begin{array}{llll}10 & 20 & 30 & 40 \\ 50\end{array}\)
a b c def

\subsection*{10.8 Focus on Problem Solving and Program Design: A Case Study}

As a programmer for the Home Software Company, you are asked to develop a function named do11arFormat that inserts commas and a \(\$\) sign at the appropriate locations in a string object containing an unformatted dollar amount. As an argument, the function should accept a reference to a string object. You may assume the string object contains a value such as 1084567.89 . The function should modify the string object so it contains a formatted dollar amount, such as \(\$ 1,084,567.89\).

The code for the dollarFormat function is as follows:
```

void dollarFormat(string \&currency)
{
int dp;
dp = currency.find('.'); // Find decimal point
if (dp > 3) // Insert commas
{
for (int x = dp - 3; x > 0; x -= 3)
currency.insert(x, ",");
}
currency.insert(0, "\$"); // Insert dollar sign
}

```

The function defines an int variable named dp. This variable is used to hold the position of the unformatted number's decimal point. This is accomplished with the statement:
```

dp = currency.find('.');

```

The string class's find member function returns the position number in the string where the '.' character is found. An if statement determines if the number has more than three numbers preceding the decimal point:
```

if (dp > 3)

```

If the decimal point is at a position greater than 3 , then the function inserts commas in the string with the following loop:
```

for (int x = dp - 3; x > 0; x -= 3)
currency.insert(x, ",");

```

Finally, a \$ symbol is inserted at position 0 (the first character in the string).
Program 10-24 demonstrates the function.

\section*{Program 10-24}
```

// This program lets the user enter a number. The
// dollarFormat function formats the number as
// a dollar amount.
\#include <iostream>
\#include <string>
using namespace std;
// Function prototype

```

\section*{Program 10-24 (continued)}
```

void dollarFormat(string \&);
int main ()
{
string input;
// Get the dollar amount from the user.
cout << "Enter a dollar amount in the form nnnnn.nn : ";
cin >> input;
dollarFormat(input);
cout << "Here is the amount formatted:\n";
cout << input << endl;
return 0;
}
//***************************************************************
// Definition of the dollarFormat function. This function
// accepts a string reference object, which is assumed
// to hold a number with a decimal point. The function
// formats the number as a dollar amount with commas and *
// a \$ symbol.
/|****************************************************************
void dollarFormat(string \&currency)
{
int dp;
dp = currency.find('.'); // Find decimal point
if (dp > 3) // Insert commas
{
for (int x = dp - 3; x > 0; x -= 3)
currency.insert(x, ",");
}
currency.insert(0, "\$"); // Insert dollar sign
}

```

\section*{Program Output with Example Input Shown in Bold}

Enter a dollar amount in the form nnnnn.nn: 1084567.89 Enter Here is the amount formatted:
\$1, 084, 567. 89

\section*{Review Questions and Exercises}

\section*{Short Answer}
1. What header file must you include in a program using character-testing functions such as isalpha and isdigit?
2. What header file must you include in a program using the character conversion functions toupper and tolower?
3. Assume c is a char variable. What value does c hold after each of the following statements executes?
```

Statement Contents of c
c = toupper('a');
c = toupper('B');
c = tolower('D');
c = toupper('e');

```
4. Look at the following code. What value will be stored in s after the code executes?
```

char name[10];
int s;
strcpy(name, "Jimmy");
s = strlen(name);

```
5. What header file must you include in a program using string functions such as strien and strcpy?
6. What header file must you include in a program using string/numeric conversion functions such as atoi and atof?
7. What header file must you include in a program using string class objects?
8. How do you compare string class objects?

\section*{Fill-in-the-Blank}
9. Character-testing functions are prototyped in the header file \(\qquad\) .
10. The \(\qquad\) function returns true if the character argument is a letter of the alphabet.
11. The \(\qquad\) function returns true if the character argument is a digit.
12. \(\qquad\) , \(\longrightarrow\) , \(\qquad\) and \(\qquad\) are whitespace characters.
13. The \(\qquad\) function returns the uppercase equivalent of its character argument.
14. The \(\qquad\) function returns the lowercase equivalent of its character argument.
15. The \(\qquad\) file must be included in a program that uses character-testing functions.
16. A \(\qquad\) is a sequence of characters terminated by a null character.
17. To \(\qquad\) two strings means to append one string to the other.
18. The \(\qquad\) function concatenates two strings.
19. The \(\qquad\) function copies one string to another.
20. The \(\qquad\) function searches for a string inside of another one.
21. Slash zero ' 10 ' stands for the ASCII code \(\qquad\) .
22. The \(\qquad\) function copies, at most, \(n\) number of characters from one string to another.
23. The \(\qquad\) function returns the value of a string converted to an integer.
24. The \(\qquad\) function returns the value of a string converted to a long integer.
25. The \(\qquad\) function returns the value of a string converted to a float.
26. To use a string object, the header file \(\qquad\) needs to be included.

\section*{Algorithm Workbench}
27. The following if statement determines whether choice is equal to ' \(Y\) ' or ' y ':
```

if (choice == 'Y' || choice == 'y')

```

Simplify this statement by using either the toupper or tolower function.
28. Assume that mystr is a char array holding a C-string. Write code that prints only those characters that are in lowercase.
29. Look at the following character arrays:
char fromstr[10], tostr[10];
Write code that copies characters from fromstr to tostr without using any string library functions.
30. Look at the following statements:
char chars[20];
string stringValue;
Write code that swaps the first and last characters in the variable chars holding a C-string. Write another version for the variable stringValue.
31. Write a function that accepts a pointer to a C-string as its argument. The function should count the number of times the character ' \(w\) ' occurs in the argument and return that number.
32. Assume str1 and str2 are string class objects. Write code that returns true if str1 is a substring of str2 or str2 is a substring of str1.

\section*{True or False}
33. T F Character-testing functions, such as isupper, accept strings as arguments and test each character in the string.
34. T F If toupper's argument is already uppercase, it is returned as is, with no changes.
35. T F If tolower's argument is already lowercase, it will be inadvertently converted to uppercase.
36. T F The character-testing functions return a nonzero number if the test condition passes.
37. T F If the starting address of a C-string is passed into a pointer parameter, it can be assumed that all the characters, from that address up to the byte that holds the null terminator, are part of the string.
38. T F The strcat function performs bound checking before appending one string at the end of another so that no overflow occurs while appending.
39. T F The expression (!strcmp(firstString, secondString)) returns true if the strings are unequal.
40. T F The to_string function converts only integers to strings.
41. T F The strcpy function performs no bounds checking on the first argument.
42. T F There is no difference between " 847 " and 847 .

\section*{Find the Errors}

Each of the following programs or program segments has errors. Find as many as you can.
```

43. char str[] = "He11o";
str[0] = "Y";
str[5] = 'w';
44. char str[] = "172";
int eight = str[0] + str[1];
char nine = atoi(str[1]) + atoi(str[2]);
45. char string1[] = "Bi11y";
char string2[] = " Bob Jones";
strcat(string1, string2);
46. string str3, str1= "A";
string str2 = "a";
str3 = (str1++) + (++str2);
```

\section*{Programming Challenges}

\section*{1. String Concatenation}

Write a function that accepts two C-string pointers as arguments and returns a pointer to another C-string. The function should concatenate the two strings passed as arguments separated by a blank space, and return a pointer to the concatenated string. Demonstrate the function using a program. Do not use any string library functions.
2. Backward String

Write a function that accepts a pointer to a C-string as an argument and displays its contents backward. For instance, if the string argument is "Gravity" the function should display "ytivarG". Demonstrate the function in a program that asks the user to input a string then passes it to the function.

\section*{3. Word Counter}

Write a function that accepts a pointer to a C-string as an argument and returns the number of words contained in the string. For instance, if the string argument is "Four score and seven years ago" the function should return the number 6. Demonstrate the function in a program that asks the user to input a string then passes it to the function. The number of words in the string should be displayed on the screen. Optional Exercise: Write an overloaded version of this function that accepts a string class object as its argument.

\section*{4. Average Number of Letters}

Modify the program you wrote for Programming Challenge 3 (Word Counter), so it also displays the average number of letters in each word.

\section*{5. Sentence Capitalizer}

Write a function that accepts a pointer to a C-string as an argument and capitalizes the first character of each sentence in the string. For instance, if the string argument is "hello. my name is Joe. what is your name?" the function should manipulate the string so that it contains "Hello. My name is Joe. What is your name?"

Demonstrate the function in a program that asks the user to input a string then passes it to the function. The modified string should be displayed on the screen. Optional Exercise: Write an overloaded version of this function that accepts a string class object as its argument.

\section*{6. Vowels and Consonants}

Write a function that accepts a pointer to a C-string as its argument. The function should count the number of vowels appearing in the string and return that number.
Write another function that accepts a pointer to a C -string as its argument. This function should count the number of consonants appearing in the string and return that number.
Demonstrate these two functions in a program that performs the following steps:
1. The user is asked to enter a string.
2. The program displays the following menu:
A) Count the number of vowels in the string
B) Count the number of consonants in the string
C) Count both the vowels and consonants in the string
D) Enter another string
E) Exit the program
3. The program performs the operation selected by the user and repeats until the user selects E to exit the program.

\section*{7. Name Arranger}

Write a program that asks for the user's first, middle, and last names. The names should be stored in three different character arrays. The program should then store, in a fourth array, the name arranged in the following manner: the last name followed by a comma and a space, followed by the first name and a space, followed by the middle name. For example, if the user entered "Carol Lynn Smith", it should store "Smith, Carol Lynn" in the fourth array. Display the contents of the fourth array on the screen.

\section*{8. Guessing Game}

Write a function for a word guessing game that takes two strings current and correct, and a single character guess. The string current should contain underscores (_) to indicate missing letters. The function should replace the underscores with the supplied character guess at the positions matching in correct and return the number of times the character can be found in correct. If the character supplied is not found, return 0 . For example, when current is "p_g_mm_g", correct is "programming", and guess equals ' \(r\) ', the function should change current to "pr_gr_mm_g" and return 2.

\section*{9. Abbreviation of Name}

Write a program that asks the user for his/her full name. The program should display his/her initials. For example, if the name is "Paul Mathews", the program will display "P. M.".
Input Validation: Accept only alphabets and blanks in name.
10. replaceSubstring Function

Write a function named replaceSubstring. The function should accept three C-string or string object arguments. Let's call them string1, string2, and string3. It should search string1 for all occurrences of string2. When it finds an occurrence of
string2, it should replace it with string3. For example, suppose the three arguments have the following values:
```

string1: "the dog jumped over the fence"
string2: "the"
string3: "that"

```

With these three arguments, the function would return a string object with the value "that dog jumped over that fence." Demonstrate the function in a complete program.

\section*{11. Case Manipulator}

Write a program with three functions: upper, lower, and reverse. The upper function should accept a pointer to a C -string as an argument. It should step through each character in the string, converting it to uppercase. The lower function, too, should accept a pointer to a C-string as an argument. It should step through each character in the string, converting it to lowercase. Like upper and lower, reverse should also accept a pointer to a string. As it steps through the string, it should test each character to determine whether it is uppercase or lowercase. If a character is uppercase, it should be converted to lowercase. Likewise, if a character is lowercase, it should be converted to uppercase.
Test the functions by asking for a string in function main, then passing it to them in the following order: reverse, lower, and upper.

\section*{12. Validity of Filenames}

A certain operating system specifies the following restrictions for naming files:
- Filenames must be, at the most, of eight characters.
- Filenames may have alphabets, digits, or the characters "_" and "-".
- Filenames should begin with an alphabet.
- Filenames must have a three-character extension name having only alphabets.

Write a function that accepts a filename and its extension name as arguments. It should return 1 if the filename is valid and 0 if it is not. Demonstrate the function in a program.

\section*{13. Time Conversion}

Write a function that takes a C-string holding a time in the format hh:mm, and prints the time in AM/PM notation, with AM or PM at the end, and hh less than or equal to 12 .

\section*{14. Word Separator}

Write a program that accepts as input a sentence in which all of the words are run together, but the first character of each word is uppercase. Convert the sentence to a string in which the words are separated by spaces and only the first word starts with an uppercase letter. For example, the string "StopAndSmellTheRoses." would be converted to "Stop and smell the roses."

\section*{15. Character Analysis}

If you have downloaded this book's source code, you will find a file named text.txt in the Chapter 10 folder. Write a program that reads the file's contents and determines the following:
- The number of uppercase letters in the file
- The number of lowercase letters in the file
- The number of digits in the file

\section*{16. Pig Latin}

Write a program that reads a sentence as input and converts each word to "Pig Latin." In one version, to convert a word to Pig Latin, you remove the first letter and place that letter at the end of the word. Then you append the string "ay" to the word. Here is an example:
English: I SLEPT MOST OF THE NIGHT
Pig Latin: IAY LEPTSAY OSTMAY FOAY HETAY IGHTNAY

\section*{17. Morse Code Converter}

Morse code is a code where each letter of the English alphabet, each digit, and various punctuation characters are represented by a series of dots and dashes. Table 10-10 shows part of the code.
Write a program that asks the user to enter a string then converts that string to Morse code.

\section*{Table 10-10 Morse Code}
\begin{tabular}{|c|c|c|c|c|c|c|c|}
\hline Character & Code & Character & Code & Character & Code & Character & Code \\
\hline space & space & 6 & -.... & G & --. & Q & --. - \\
\hline comma & --..-- & 7 & --... & H & .... & R & .-. \\
\hline period & .-.-. & 8 & ---.. & I & . & S & \(\ldots\) \\
\hline question mark & ..--. & 9 & ---- & \(J\) & .--- & T & - \\
\hline 0 & ----- & A & .- & K & -. - & u & ..- \\
\hline 1 & .---- & B & -... & L & .-. & V & ...- \\
\hline 2 & ..--- & C & -.-. & M & -- & W & .-- \\
\hline 3 & ...-- & D & -. & N & - & X & -.. - \\
\hline 4 & ....- & E & . & 0 & --- & Y & -- \\
\hline 5 & ..... & F & ..- & P & --. & Z & --. \\
\hline
\end{tabular}

\section*{18. Phone Number List}

Write a program that has an array of at least 10 string objects that hold people's names and phone numbers. You may make up your own strings, or use the following:
"Alejandra Cruz, 555-1223"
"Joe Looney, 555-0097"
"Geri Palmer, 555-8787"
"Li Chen, 555-1212"
"Holly Gaddis, 555-8878"
"Sam Wiggins, 555-0998"
"Bob Kain, 555-8712"
"Tim Haynes, 555-7676"
"Warren Gaddis, 555-9037"
"Jean James, 555-4939"
"Ron Palmer, 555-2783"

The program should ask the user to enter a name or partial name to search for in the array. Any entries in the array that match the string entered should be displayed. For example, if the user enters "Palmer" the program should display the following names from the list:

Geri Palmer, 555-8787
Ron Palmer, 555-2783

\section*{19. Check Writer}

Write a program that displays a simulated paycheck. The program should ask the user to enter the date, the payee's name, and the amount of the check (up to \(\$ 10,000\) ). It should then display a simulated check with the dollar amount spelled out, as shown here:

Date: 11/24/2018

Pay to the Order of: John Phillips \$1920.85
One thousand nine hundred twenty and 85 cents
Be sure to format the numeric value of the check in fixed-point notation with two decimal places of precision. Be sure the decimal place always displays, even when the number is zero or has no fractional part. Use either C-strings or string class objects in this program.
Input Validation: Do not accept negative dollar amounts, or amounts over \$10,000.

\section*{20. Format Checker}

Many strings have to be formatted according to a set of rules. Phone numbers, for example, depending on the country have a specified length and fixed positions for slashes or dashes. Car license numbers may first have a specific number of characters, a dash, and finally another set of digits; emails should contain a @; and software licenses and serial numbers often consist of several groups of either numbers or characters.
Write a function that verifies whether a given string (an object of the string class) conforms to a given format. The function returns a Boolean: true when the string conforms and false when it doesn't conform.

The format is defined using two lists:
- A list of type string
- A list of type int

The two lists must be interpreted in pairs. The string represents the characters that are allowed, whereas the int represents the number of times that set of characters should occur.
For example, if the string list contains "ABC" and " 12345 " and the int list contains 3 and 2 , then the string should contain \(A, B\), or \(C\) thrice followed twice by \(1,2,3,4\), or 5 .

11.11 Enumerated Data Types

\subsection*{11.1 Abstract Data Types}

CONCEPT: Abstract data types (ADTs) are data types created by the programmer. ADTs have their own range (or domain) of data and their own sets of operations that may be performed on them.

The term abstract data type, or ADT, is very important in computer science and is especially significant in object-oriented programming. This chapter introduces you to the structure, which is one of C++'s mechanisms for creating abstract data types.

\section*{Abstraction}

An abstraction is a general model of something. It is a definition that includes only the general characteristics of an object. For example, the term "dog" is an abstraction. It defines a general type of animal. The term captures the essence of what all dogs are without specifying the detailed characteristics of any particular type of dog. According to Webster's New Collegiate Dictionary, a dog is a highly variable carnivorous domesticated mammal (Canis familiaris) probably descended from the common wolf.
In real life, however, there is no such thing as a mere "dog." There are specific types of dogs, each with its own set of characteristics. There are poodles, cocker spaniels, Great

Danes, rottweilers, and many other breeds. There are small dogs and large dogs. There are gentle dogs and ferocious dogs. They come in all shapes, sizes, and dispositions. A real-life dog is not abstract. It is concrete.

\section*{Data Types}

C++ has several primitive data types, or data types that are defined as a basic part of the language, as shown in Table 11-1.

\section*{Table 11-1 Primitive Data Types}
\begin{tabular}{lll}
\hline bool & short int & long long int \\
char & unsigned short int & unsigned long long int \\
char_16_t & int & \\
char_32_t & unsigned int & float \\
wchar_t & long int & double \\
unsigned char & unsigned long int & long double \\
\hline
\end{tabular}

A data type defines what values a variable may hold. Each data type listed in Table 11-1 has its own range of values, such as \(-32,768\) to \(+32,767\) for shorts, and so forth. Data types also define what values a variable may not hold. For example, integer variables may not be used to hold fractional numbers.

In addition to defining a range or domain of values that a variable may hold, data types also define the operations that may be performed on a value. All of the data types listed in Table 11-1 allow the following mathematical and relational operators to be used with them:
\[
+-* /><>=<==
\]

Only the integer data types, however, allow operations with the modulus operator (\%). So, a data type defines what values an object may hold, and the operations that may be performed on the object.

The primitive data types are abstract in the sense that a data type and a variable of that data type are not the same thing. For example, consider the following variable definition:
```

int x = 1, y = 2, z = 3;

```

In the statement above, the integer variables \(x, y\), and \(z\) are defined. They are three separate instances of the data type int. Each variable has its own characteristics ( x is set to 1 , \(y\) is set to 2 , and \(z\) is set to 3 ). In this example, the data type int is the abstraction, and the variables \(x, y\), and \(z\) are concrete occurrences.

\section*{Abstract Data Types}

An abstract data type (ADT) is a data type created by the programmer and is composed of one or more primitive data types. The programmer decides what values are acceptable for the data type, as well as what operations may be performed on the data type. In many cases, the programmer designs his or her own specialized operations.

For example, suppose a program is created to simulate a 12 -hour clock. The program could contain three ADTs: Hours, Minutes, and Seconds. The range of values for the Hours data type would be the integers 1 through 12. The range of values for the Minutes and Seconds data types would be 0 through 59. If an Hours object is set to 12 and then incremented, it will then take on the value 1 . Likewise, if a Minutes object or a Seconds object is set to 59 then incremented, it will take on the value 0 .
Abstract data types often combine several values. In the clock program, the Hours, Minutes, and Seconds objects could be combined to form a single Clock object. In this chapter, you will learn how to combine variables of primitive data types to form your own data structures, or ADTs.

\subsection*{11.2 Structures}

CONCEPT: C++ allows you to group several variables together into a single item known as a structure.

So far, you've written programs that keep data in individual variables. If you need to group items together, C++ allows you to create arrays. The limitation of arrays, however, is that all the elements must be of the same data type. Sometimes a relationship exists between items of different types. For example, a payroll system might keep the variables shown in Table 11-2. These variables hold data for a single employee.

Table 11-2 Variables in a Payroll System
\begin{tabular}{ll}
\hline Variable Definition & Data Held \\
\hline int empNumber; & Employee number \\
string name; & Employee's name \\
double hours; & Hours worked \\
double payRate; & Hourly pay rate \\
double grossPay; & Gross pay \\
\hline
\end{tabular}

All of the variables listed in Table 11-2 are related because they can hold data about the same employee. Their definition statements, though, do not make it clear that they belong together. To create a relationship between variables, C++ gives you the ability to package them together into a structure.
Before a structure can be used, it must be declared. Here is the general format of a structure declaration:
```

struct tag
{
variab7e declaration;
// ... more declarations
// may follow...
};

```

The tag is the name of the structure. As you will see later, it's used like a data type name. The variable declarations that appear inside the braces declare members of the structure. Here is an example of a structure declaration that holds the payroll data listed in Table 11-2:
```

struct PayRol1
{
int empNumber; // Employee number
string name; // Employee's name
double hours; // Hours worked
double payRate; // Hourly pay rate
double grossPay; // Gross pay
};

```

This declaration declares a structure named PayRol1. The structure has five members: empNumber, name, hours, payRate, and grossPay.

WARNING! Notice a semicolon is required after the closing brace of the structure declaration.

NOTE: In this text, we begin the names of structure tags with an uppercase letter. This visually differentiates these names from the names of variables.

NOTE: The structure declaration shown contains three double members, each declared on a separate line. The three could also have been declared on the same line, as
```

struct PayRol1
{
int empNumber;
string name;
double hours, payRate, grossPay;
};

```

Many programmers prefer to place each member declaration on a separate line, however, for increased readability.

It's important to note the structure declaration in our example does not define a variable. It simply tells the compiler what a PayRoll structure is made of. In essence, it creates a new data type named PayRol1. You can define variables of this type with simple definition statements, just as you would with any other data type. For example, the following statement defines a variable named depthead:
```

PayRol1 deptHead;

```

The data type of deptHead is the PayRoll structure. The structure tag, PayRoll, is listed before the variable name, just as the word int or double would be listed to define variables of those types.

Remember that structure variables are actually made up of other variables known as members. Because deptHead is a PayRoll structure, it contains the following members:
```

empNumber, an int
name, astring object
hours, adouble
payRate, adouble
grossPay, adouble

```

Figure 11-1 illustrates this.

Figure 11-1 A structure and its members

Just as it's possible to define multiple int or double variables, it's possible to define multiple structure variables in a program. The following statement defines three PayRoll variables: deptHead, foreman, and associate:
PayRoll deptHead, foreman, associate;

Figure 11-2 illustrates the existence of these three variables.
Figure 11-2 Multiple structure variables

Each of the variables defined in this example is a separate instance of the PayRoll structure and contains its own members. An instance of a structure is a variable that exists in memory. It contains within it all the members described in the structure declaration.

Although the structure variables in the example are separate, each contains members with the same name. (In the next section, you'll see how to access these members.) Here are some other examples of structure declarations and variable definitions:
```

struct Time
{
int hour;
int minutes;
int seconds;
};
// Definition of the
// structure variable now.
Time now;

```
```

struct Date
{
int day;
int month;
int year;
};
// Definition of the structure
// variable today.
Date today;

```

In review, there are typically two steps to implementing structures in a program:
- Create the structure declaration. This establishes the tag (or name) of the structure and a list of items that are members.
- Define variables (or instances) of the structure and use them in the program to hold data.

\subsection*{11.3 Accessing Structure Members}

CONCEPT: The dot operator (.) allows you to access structure members in a program.

C++ provides the dot operator (a period) to access the individual members of a structure. Using our example of deptHead as a PayRoll structure variable, the following statement demonstrates how to access the empNumber member:
```

deptHead.empNumber = 475;

```

In this statement, the number 475 is assigned to the empNumber member of deptHead. The dot operator connects the name of the member variable with the name of the structure variable it belongs to. The following statements assign values to the empNumber members of the deptHead, foreman, and associate structure variables:
```

deptHead.empNumber = 475;
foreman.empNumber = 897;
associate.empNumber = 729;

```

With the dot operator, you can use member variables just like regular variables. For example, these statements display the contents of deptHead's members:
```

cout << deptHead.empNumber << endl;
cout << deptHead.name << endl;
cout << deptHead.hours << endl;
cout << deptHead.payRate << endl;
cout << deptHead.grossPay << endl;

```

Program 11-1 is a complete program that uses the PayRoll structure.

\section*{Program 11-1}
```

// This program demonstrates the use of structures.
\#include <iostream>
\#include <string>
\#include <iomanip>
using namespace std;
struct PayRol1
{
int empNumber; // Employee number
string name; // Employee's name
double hours; // Hours worked
double payRate; // Hourly payRate
double grossPay; // Gross pay
};
int main()
{
PayRol1 employee; // employee is a PayRol1 structure.
// Get the employee's number.
cout << "Enter the employee's number: ";
cin >> employee.empNumber;
// Get the employee's name.
cout << "Enter the employee's name: ";
cin.ignore(); // To skip the remaining '\n' character
getline(cin, employee.name);
// Get the hours worked by the employee.
cout << "How many hours did the employee work? ";
cin >> employee.hours;
// Get the employee's hourly pay rate.
cout << "What is the employee's hourly payRate? ";
cin >> employee.payRate;
// Calculate the employee's gross pay.
employee.grossPay = employee.hours * employee.payRate;
// Display the employee data.
cout << "Here is the employee's payroll data:\n";
cout << "Name: " << employee.name << endl;
cout << "Number: " << employee.empNumber << endl;
cout << "Hours worked: " << employee.hours << endl;
cout << "Hourly payRate: " << employee.payRate << endl;
cout << fixed << showpoint << setprecision(2);
cout << "Gross Pay: \$" << employee.grossPay << endl;
return 0;
}

```

\section*{Program 11-1}
(continued)

\section*{Program Output with Example Input Shown in Bold}

Enter the employee's number: 489 Enter
Enter the employee's name: Jill Smith Enter
How many hours did the employee work? 40 Enter
What is the employee's hourly pay rate? 20 Enter
Here is the employee's payroll data:
Name: Jill Smith
Number: 489
Hours worked: 40
Hourly pay rate: 20
Gross pay: \$800.00

NOTE: Program 11-1 has the following call, in line 26 , to cin's ignore member function:
```

cin.ignore();

```

Recall that the ignore function causes cin to ignore the next character in the input buffer. This is necessary for the getline function to work properly in the program.

NOTE: The contents of a structure variable cannot be displayed by passing the entire variable to cout. For example, assuming employee is a PayRoll structure variable, the following statement will not work:
```

cout << employee << endl; // Will not work!

```

Instead, each member must be separately passed to cout.

As you can see from Program 11-1, structure members that are of a primitive data type can be used with cin, cout, mathematical statements, and any operation that can be performed with regular variables. The only difference is that the structure variable name and the dot operator must precede the name of a member. Program 11-2 shows the member of a structure variable being passed to the pow function.

\section*{Program 11-2}
```

// This program stores data about a circle in a structure.
\#include <iostream>
\#include <cmath> // For the pow function
\#include <iomanip>
using namespace std;
// Constant for pi.
const double PI = 3.14159;

```
```

9
10 // Structure declaration
1 1 struct Circle
12 {

```
```

    double radius; // A circle's radius
    ```
    double radius; // A circle's radius
    double diameter; // A circle's diameter
    double diameter; // A circle's diameter
    double area; // A circle's area
    double area; // A circle's area
};
};
int main()
int main()
{
{
    Circle c; // Define a structure variable
    Circle c; // Define a structure variable
    // Get the circle's diameter.
    // Get the circle's diameter.
    cout << "Enter the diameter of a circle: ";
    cout << "Enter the diameter of a circle: ";
    cin >> c.diameter;
    cin >> c.diameter;
    // Calculate the circle's radius.
    // Calculate the circle's radius.
    c.radius = c.diameter / 2;
    c.radius = c.diameter / 2;
    // Calculate the circle's area.
    // Calculate the circle's area.
    c.area = PI * pow(c.radius, 2.0);
    c.area = PI * pow(c.radius, 2.0);
    // Display the circle data.
    // Display the circle data.
    cout << fixed << showpoint << setprecision(2);
    cout << fixed << showpoint << setprecision(2);
    cout << "The radius and area of the circle are:\n";
    cout << "The radius and area of the circle are:\n";
    cout << "Radius: " << c.radius << endl;
    cout << "Radius: " << c.radius << endl;
    cout << "Area: " << c.area << endl;
    cout << "Area: " << c.area << endl;
    return 0;
    return 0;
}
```

}

```

\section*{Program Output with Example Input Shown in Bold}

Enter the diameter of a circle: 10 Enter
The radius and area of the circle are:
Radius: 5
Area: 78.54

\section*{Comparing Structure Variables}

You cannot perform comparison operations directly on structure variables. For example, assume circle1 and circle2 are Circle structure variables. The following statement will cause an error:
```

if (circle1 == circle2) // Error!

```

In order to compare two structures, you must compare the individual members, as shown in the following code:
```

if (circle1.radius == circle2.radius \&\&
circle1.diameter == circle2.diameter \&\&
circle1.area == circle2.area)

```

\subsection*{11.4 Initializing a Structure \\ CONCEPT: The members of a structure variable may be initialized with starting values when the structure variable is defined.}

A structure variable may be initialized when it is defined, in a fashion similar to the initialization of an array. Assume the following structure declaration exists in a program:
```

struct CityInfo
{
string cityName;
string state;
long population;
int distance;
};

```

A variable may then be defined with an initialization list, as shown in the following:
```

CityInfo location = {"Asheville", "NC", 80000, 28};

```

This statement defines the variable location. The first value in the initialization list is assigned to the first declared member, the second value in the initialization list is assigned to the second member, and so on. The location variable is initialized in the following manner:

The string "Asheville" is assigned to location.cityName
The string "NC" is assigned to location.state
80000 is assigned to location. population
28 is assigned to location.distance
You do not have to provide initializers for all the members of a structure variable. For example, the following statement only initializes the cityName member of location:
```

CityInfo location = {"Tampa"};

```

The state, population, and distance members are left uninitialized. The following statement only initializes the cityName and state members, while leaving population and distance uninitialized:
```

CityInfo location = {"Atlanta", "GA"};

```

If you leave a structure member uninitialized, you must leave all the members that follow it uninitialized as well. C++ does not provide a way to skip members in a structure. For example, the following statement, which attempts to skip the initialization of the population member, is not legal:
```

CityInfo location = {"Knoxville", "TN", , 90}; // Illegal!

```

Program 11-3 demonstrates the use of partially initialized structure variables.

\section*{Program 11-3}
```

// This program demonstrates partially initialized
// structure variables.
\#include <iostream>

```
```

\#include <string>
\#include <iomanip>
using namespace std;
struct EmployeePay
{
string name; // Employee name
int empNum; // Employee number
double payRate; // Hourly pay rate
double hours; // Hours worked
double grossPay; // Gross pay
};
int main()
{
EmployeePay employee1 = {"Betty Ross", 141, 18.75};
EmployeePay employee2 = {"Jil1 Sandburg", 142, 17.50};
cout << fixed << showpoint << setprecision(2);
// Calculate pay for employee1
cout << "Name: " << employee1.name << endl;
cout << "Employee Number: " << employee1.empNum << endl;
cout << "Enter the hours worked by this employee: ";
cin >> employee1.hours;
employee1.grossPay = employee1.hours * employee1.payRate;
cout << "Gross Pay: " << employee1.grossPay << endl << endl;
// Calculate pay for employee2
cout << "Name: " << employee2.name << end1;
cout << "Employee Number: " << employee2.empNum << endl;
cout << "Enter the hours worked by this employee: ";
cin >> employee2.hours;
emp1oyee2.grossPay = emp1oyee2.hours * emp1oyee2.payRate;
cout << "Gross Pay: " << employee2.grossPay << endl;
return 0;
}

```

Program Output with Example Input Shown in Bold
Name: Betty Ross
Employee Number: 141
Enter the hours worked by this employee: 40 Enter
Gross Pay: 750.00
Name: Jill Sandburg
Employee Number: 142
Enter the hours worked by this employee: 20 Enter
Gross Pay: 350.00

Beginning with C++ 11, the \(=\) sign is optional when initializing a structure variable. For example, in C++ 11, we could define a CityInfo variable and initialize with the following statement:
```

CityInfo location {"Asheville", "NC", 80000, 28};

```

\section*{Checkpoint}
11.1 Write a structure declaration to hold the following data about a savings account:

Account Number (string object)
Account Balance (double)
Interest Rate (double)
Average Monthly Balance (double)
11.2 Write a definition statement for a variable of the structure you declared in Question 11.1. Initialize the members with the following data:
Account Number: ACZ42137-B12-7
Account Balance: \$4512.59
Interest Rate: 4\%
Average Monthly Balance: \$4217.07
11.3 The following program skeleton, when complete, asks the user to enter these data about his or her favorite movie:
Name of movie
Name of the movie's director
Name of the movie's producer
The year the movie was released
Complete the following program by declaring the structure that holds this data, defining a structure variable, and writing the individual statements necessary.
```

\#include <iostream>
using namespace std;
// Write the structure declaration here to hold the movie data.
int main()
{
// define the structure variable here.
cout << "Enter the following data about your\n";
cout << "favorite movie.\n";
cout << "name: ";
// Write a statement here that lets the user enter the
// name of a favorite movie. Store the name in the
// structure variable.
cout << "Director: ";
// Write a statement here that lets the user enter the
// name of the movie's director. Store the name in the
// structure variable.

```
```

    cout << "Producer: ";
    // Write a statement here that lets the user enter the
    // name of the movie's producer. Store the name in the
    // structure variable.
        cout << "Year of release: ";
        // Write a statement here that lets the user enter the
        // year the movie was released. Store the year in the
        // structure variable.
        cout << "Here is data on your favorite movie:\n";
        // Write statements here that display the data.
        // just entered into the structure variable.
        return 0;
    }

```

\subsection*{11.5 Arrays of Structures}

CONCEPT: Arrays of structures can simplify some programming tasks.
In Chapter 7, you saw that data can be stored in two or more arrays, with a relationship established between the arrays through their subscripts. Because structures can hold several items of varying data types, a single array of structures can be used in place of several arrays of regular variables.

An array of structures is defined like any other array. Assume the following structure declaration exists in a program:
```

struct BookInfo
{
string title;
string author;
string publisher;
double price;
};

```

The following statement defines an array, bookList, that has 20 elements. Each element is a BookInfo structure.

BookInfo bookList[20];
Each element of the array may be accessed through a subscript. For example, bookList [0] is the first structure in the array, bookList [1] is the second, and so forth. To access a member of any element, simply place the dot operator and member name after the subscript. For example, the following expression refers to the title member of bookList[5]:
```

bookList[5].title

```

The following loop steps through the array, displaying the data stored in each element:
```

for (int index = 0; index < 20; index++)
{
cout << bookList[index].title << endl;
cout << bookList[index].author << endl;
cout << bookList[index].publisher << endl;
cout << bookList[index].price << endl << endl;
}

```

Program 11-4 calculates and displays payroll data for three employees. It uses a single array of structures.

\section*{Program 11-4}
```

// This program uses an array of structures.
\#include <iostream>
\#include <iomanip>
using namespace std;
struct PayInfo
{
int hours; // Hours worked
double payRate; // Hourly pay rate
};
int main()
{
const int NUM_WORKERS = 3; // Number of workers
PayInfo workers[NUM_WORKERS]; // Array of structures
int index; // Loop counter
// Get employee pay data.
cout << "Enter the hours worked by " << NUM_WORKERS
<< " employees and their hourly rates.\n";
for (index = 0; index < NUM_WORKERS; index++)
{
// Get the hours worked by an employee.
cout << "Hours worked by employee \#" << (index + 1);
cout << ": ";
cin >> workers[index].hours;
// Get the employee's hourly pay rate.
cout << "Hourly pay rate for employee \#";
cout << (index + 1) << ": ";
cin >> workers[index].payRate;
cout << endl;
}
// Display each employee's gross pay.
cout << "Here is the gross pay for each employee:\n";
cout << fixed << showpoint << setprecision(2);
for (index = 0; index < NUM_WORKERS; index++)
{
double gross;
gross = workers[index].hours * workers[index].payRate;
cout << "Employee \#" << (index + 1);
cout << ": \$" << gross << endl;
}
return 0;
}

```

\section*{Program Output with Example Input Shown in Bold}
```

Enter the hours worked by 3 employees and their hourly rates.
Hours worked by employee \#1: 10 Enter
Hourly pay rate for employee \#1: 9.75 Enter
Hours worked by employee \#2: 20 Enter
Hourly pay rate for employee \#2: 10.00 Enter
Hours worked by employee \#3: 40 Enter
Hourly pay rate for employee \#3: 20.00 Enter
Here is the gross pay for each employee:
Employee \#1: \$97.50
Employee \#2: \$200.00
Employee \#3: \$800.00

```

\section*{Initializing a Structure Array}

To initialize a structure array, simply provide an initialization list for one or more of the elements. For example, the array in Program 11-4 could have been initialized as follows:
```

PayInfo workers[NUM_WORKERS] = {
{10, 9.75 },
{15, 8.62 },
{40, 15.65}
};

```

As in all single-dimensional arrays, you can initialize all or part of the elements in an array of structures, as long as you do not skip elements.

\subsection*{11.6 Focus on Software Engineering: Nested Structures \\ CONCEPT: It's possible for a structure variable to be a member of another structure variable.}

Sometimes it's helpful to nest structures inside other structures. For example, consider the following structure declarations:
```

struct Costs
{
double wholesale;
double retail;
};
struct Item
{
string partNum;
string description;
Costs pricing;
};

```

The Costs structure has two members: wholesale and retail, both doubles. Notice the third member of the Item structure, pricing, is a Costs structure. Assume the variable widget is defined as follows:
```

Item widget;

```

The following statements show examples of accessing members of the pricing variable, which is inside widget:
```

widget.pricing.wholesale = 100.0;
widget.pricing.retail = 150.0;

```

Program 11-5 gives a more elaborate illustration of nested structures.

\section*{Program 11-5}
```

// This program uses nested structures.

```
\#include <iostream>
\#include <string>
using namespace std;
// The Date structure holds data about a date.
struct Date
\{
    int month;
    int day;
    int year;
\};
// The Place structure holds a physical address.
struct Place
\{
    string address;
    string city;
    string state;
    string zip;
\};
// The EmployeeInfo structure holds an employee's data.
struct EmployeeInfo
\{
    string name;
    int employeeNumber;
    Date birthDate; // Nested structure
    Place residence; // Nested structure
\};
int main()
\{
    // Define a structure variable to hold info about the manager.
    EmployeeInfo manager;
    // Get the manager's name and employee number
    cout << "Enter the manager's name: ";
    getline(cin, manager.name);
    cout << "Enter the manager's employee number: ";
    cin >> manager.employeeNumber;
    // Get the manager's birth date
    cout << "Now enter the manager's date of birth. In";
    cout << "Month (up to 2 digits): ";
    cin >> manager.birthDate.month;
    cout << "Day (up to 2 digits): ";
    cin >> manager.birthDate.day;
    cout << "Year: ";
    cin >> manager.birthDate.year;
    cin.ignore(); // Skip the remaining newline character
    // Get the manager's residence information
    cout << "Enter the manager's street address: ";
    getline(cin, manager.residence.address);
    cout << "City: ";
    getline(cin, manager.residence.city) ;
    cout << "State: ";
    getline(cin, manager.residence.state);
    cout << "ZIP Code: ";
    getline(cin, manager.residence.zip);
    // Display the information just entered
    cout << "\nHere is the manager's information:\n";
    cout << manager. name << endl;
    cout << "Employee number " << manager.employeeNumber << endl;
    cout << "Date of birth: ";
    cout << manager.birthDate.month << "-";
    cout << manager.birthDate.day << "-";
    cout << manager.birthDate.year << endl;
    cout << "Place of residence:\n";
    cout << manager.residence.address << endl;
    cout << manager.residence.city << ", ";
    cout << manager.residence.state << " ";
    cout << manager. residence.zip << endl;
    return 0;

\section*{Program Output with Example Input Shown in Bold}

Enter the manager's name: John Smith Enter
Enter the manager's employee number: 789 Enter
Now enter the manager's date of birth.
Month (up to 2 digits): 10 Enter
Day (up to 2 digits): 14 Enter
Year: 1970 Enter
Enter the manager's street address: 190 Disk Drive Enter
City: Redmond Enter
```

Program 11-5
(continued)

```
```

State: WA Enter

```
State: WA Enter
ZIP Code: 98052 Enter
ZIP Code: 98052 Enter
Here is the manager's information:
Here is the manager's information:

\section*{Checkpoint}

For Questions 11.4-11.7 below, assume the Product structure is declared as follows:
```

struct Product
{
string description; // Product description
int partNum; // Part number
double cost; // Product cost
};

```
11.4 Write a definition for an array of 100 Product structures. Do not initialize the array.
11.5 Write a loop that will step through the entire array you defined in Question 11.4, setting all the product descriptions to an empty string, all part numbers to zero, and all costs to zero.
11.6 Write the statements that will store the following data in the first element of the array you defined in Question 11.4:
Description: Claw hammer
Part Number: 547
Part Cost: \$8.29

\subsection*{11.7 Write a loop that will display the contents of the entire array you created in Question 11.4.}
11.8 Write a structure declaration named Measurement, with the following members: miles, an integer meters, a long integer

\subsection*{11.9 Write a structure declaration named Destination, with the following members: city, a string object distance, a Measurement structure (declared in Question 11.8)}

Also define a variable of this structure type.
11.10 Write statements that store the following data in the variable you defined in
Question 11.9: Question 11.9:
City: Tupelo
Miles: 375
Meters: 603,375

\subsection*{11.7 Structures as Function Arguments}

CONCEPT: Structure variables may be passed as arguments to functions.
Like other variables, the individual members of a structure variable may be used as function arguments. For example, assume the following structure declaration exists in a program:
```

struct Rectangle
{
double length;
double width;
double area;
};

```

Let's say the following function definition exists in the same program:
```

double multiply(double x, double y)
{
return x * y;
}

```

Assuming box is a variable of the Rectang1e structure type, the following function call will pass box. length into x and box.width into y . The return value will be stored in box.area.
```

box.area = multiply(box.length, box.width);

```

Sometimes it's more convenient to pass an entire structure variable into a function instead of individual members. For example, the following function definition uses a Rectangle structure variable as its parameter:
```

void showRect(Rectangle r)
{
cout << r.length << endl;
cout << r.width << endl;
cout << r.area << endl;
}

```

The following function call passes the box variable into \(r\) :
```

showRect(box);

```

Inside the function showRect, \(r\) 's members contain a copy of box's members. This is illustrated in Figure 11-3.

Once the function is called, \(r\). length contains a copy of box.length, \(r\).width contains a copy of box.width, and \(r\). area contains a copy of box.area.
Structures, like all variables, are normally passed by value into a function. If a function is to access the members of the original argument, a reference variable may be used as the parameter. Program 11-6 uses two functions that accept structures as arguments. Arguments are passed to the getItem function by reference, and to the showItem function by value.

Figure 11-3 Passing a structure variable to a function
```

showRect(box);
L
void showRect(Rectangle r)
{
cout << r.length << endl;
cout << r.width << endl;
cout << r.area << endl;
}

```

\section*{Program 11-6}
```

// This program has functions that accept structure variables
// as arguments.
\#include <iostream>
\#include <string>
\#include <iomanip>
using namespace std;
struct InventoryItem
{
int partNum; // Part number
string description; // Item description
int onHand; // Units on hand
double price; // Unit price
};
// Function Prototypes
void getItem(InventoryItem\&); // Argument passed by reference
void showItem(InventoryItem); // Argument passed by value
int main()
{
InventoryItem part;
getItem(part);
showItem(part);
return 0;
}
//***********************************************************
// Definition of function getItem. This function uses *
// a structure reference variable as its parameter. It asks *
// the user for information to store in the structure. *
|/|************************************************************

```
34
```

void getItem(InventoryItem \&p) // Uses a reference parameter
{
// Get the part number.
cout << "Enter the part number: ";
cin >> p.partNum;
// Get the part description.
cout << "Enter the part description: ";
cin.ignore(); /l Ignore the remaining newline character
getline(cin, p.description);
// Get the quantity on hand.
cout << "Enter the quantity on hand: ";
cin >> p.onHand;
// Get the unit price.
cout << "Enter the unit price: ";
cin >> p.price;
}
//**************************************************************
// Definition of function showItem. This function accepts
// an argument of the InventoryItem structure type. The
// contents of the structure is displayed.
//****************************************************************
void showItem(InventoryItem p)
{
cout << fixed << showpoint << setprecision(2);
cout << "Part Number: " << p.partNum << endl;
cout << "Description: " << p.description << endl;
cout << "Units On Hand: " << p.onHand << endl;
cout << "Price: \$" << p.price << endl;
}

```

\section*{Program Output with Example Input Shown in Bold}

Enter the part number: \(\mathbf{8 0 0}\) Enter
Enter the part description: Screwdriver Enter
Enter the quantity on hand: 135 Enter
Enter the unit price: 1.25 Enter
Part Number: 800
Description: Screwdriver
Units on Hand: 135
Price: \$1.25

Notice the InventoryItem structure declaration in Program 11-6 appears before both the prototypes and the definitions of the getItem and showItem functions. This is because both functions use an InventoryItem structure variable as their parameter. The compiler must know what InventoryItem is before it encounters any definitions for variables of that type. Otherwise, an error will occur.

\section*{Constant Reference Parameters}

Sometimes structures can be quite large. Passing large structures by value can decrease a program's performance because a copy of the structure has to be created. When a structure is passed by reference, however, it isn't copied. A reference that points to the original argument is passed instead. So, it's often preferable to pass large objects such as structures by reference.

Of course, the disadvantage of passing an object by reference is that the function has access to the original argument. It can potentially alter the argument's value. This can be prevented, however, by passing the argument as a constant reference. The showItem function from Program 11-6 is shown here, modified to use a constant reference parameter.
```

void showItem(const InventoryItem \&p)
{
cout << fixed << showpoint << setprecision(2);
cout << "Part Number: " << p.partNum << endl;
cout << "Description: " << p.description << endl;
cout << "Units on Hand: " << p.onHand << endl;
cout << "Price: \$" << p.price << endl;
}

```

This version of the function is more efficient than the original version because the amount of time and memory consumed in the function call is reduced. Because the parameter is defined as a constant, the function cannot accidentally corrupt the value of the argument.

The prototype for this version of the function is as follows:
```

void showItem(const InventoryItem\&);

```

\subsection*{11.8 Returning a Structure from a Function}

\section*{CONCEPT: A function may return a structure.}

Just as functions can be written to return an int, long, double, or other data type, they can also be designed to return a structure. Recall the following structure declaration from Program 11-2:
```

struct Circle
{
double radius;
double diameter;
double area;
};

```

A function, such as the following, could be written to return a variable of the Circle data type:
```

Circle getCircleData()
{
Circle temp; // Temporary Circle structure
temp.radius = 10.0; // Store the radius
temp.diameter = 20.0; // Store the diameter

```
```

    temp.area = 314.159; // Store the area
    return temp; // Return the temporary structure
    }

```

Notice the getCircleData function has a return data type of Circle. That means the function returns an entire Circle structure when it terminates. The return value can be assigned to any variable that is a Circle structure. The following statement, for example, assigns the function's return value to the Circle structure variable named myCircle:
```

myCircle = getCircleData();

```

After this statement executes, myCircle.radius will be set to 10.0 , myCircle.diameter will be set to 20.0 , and myCircle. area will be set to 314.159 .

When a function returns a structure, it is always necessary for the function to have a local structure variable to hold the member values that are to be returned. In the getCircleData function, the values for diameter, radius, and area are stored in the local variable temp. The temp variable is then returned from the function.

Program 11-7 is a modification of Program 11-2. The function get Info gets the circle's diameter from the user and calculates the circle's radius. The diameter and radius are stored in a local structure variable, round, which is returned from the function.

\section*{Program 11-7}
```

// This program uses a function to return a structure. This
// is a modification of Program 11-2.
\#include <iostream>
\#include <iomanip>
\#include <cmath> // For the pow function
using namespace std;
// Constant for pi.
const double PI = 3.14159;
// Structure declaration
struct Circle
{
double radius; // A circle's radius
double diameter; // A circle's diameter
double area; // A circle's area
};
// Function prototype
Circle getInfo();
int main()
{
Circle c; // Define a structure variable
// Get data about the circle.
c = getInfo();

```
```

\section*{Program Output with Example Input Shown in Bold}

Enter the diameter of a circle: 10 Enter
The radius and area of the circle are:
Radius: 5.00
Area: 78.54

NOTE: In Chapter 6, you learned that C++ only allows you to return a single value from a function. Structures, however, provide a way around this limitation. Even though a structure may have several members, a structure variable is a single value. By packaging multiple values inside a structure, you can return as many variables as you need from a function.

\subsection*{11.9 Pointers to Structures}

CONCEPT: You may take the address of a structure variable and create variables that are pointers to structures.

Defining a variable that is a pointer to a structure is as simple as defining any other pointer variable: The data type is followed by an asterisk and the name of the pointer variable. Here is an example:
```

Circle *cirPtr = nullptr;

```

This statement defines cirPtr as a pointer to a Circle structure. Look at the following code:
```

Circle myCircle = { 10.0, 20.0, 314.159 };
Circle *cirPtr = nullptr;
cirPtr = \&myCircle;

```

The first two lines define myCircle, a structure variable, and cirPtr, a pointer. The third line assigns the address of myCircle to cirPtr. After this line executes, cirPtr will point to the myCircle structure. This is illustrated in Figure 11-4.

Figure 11-4 \(A\) pointer to a structure

Indirectly accessing the members of a structure through a pointer can be clumsy, however, if the indirection operator is used. One might think the following statement would access the radius member of the structure pointed to by cirPtr, but it doesn't:
*cirPtr.radius \(=10 ;\)
The dot operator has higher precedence than the indirection operator, so the indirection operator tries to dereference cirPtr.radius, not cirPtr. To dereference the cirPtr pointer, a set of parentheses must be used.
```

(*cirPtr).radius = 10;

```

Because of the awkwardness of this notation, C++ has a special operator for dereferencing structure pointers. It's called the structure pointer operator, and it consists of a hyphen (-) followed by the greater-than symbol (>). The previous statement, rewritten with the structure pointer operator, looks like this:
```

cirPtr->radius = 10;

```

The structure pointer operator takes the place of the dot operator in statements using pointers to structures. The operator automatically dereferences the structure pointer on its left. There is no need to enclose the pointer name in parentheses.

NOTE: The structure pointer operator is supposed to look like an arrow, thus visually indicating that a "pointer" is being used.

Program 11-8 shows that a pointer to a structure may be used as a function parameter, allowing the function to access the members of the original structure argument.

\section*{Program 11-8}
```

// This program demonstrates a function that uses a

```
// pointer to a structure variable as a parameter.
\#include <iostream>
\#include <string>
\#include <iomanip>
using namespace std;
struct Student
\{
    string name; // Student's name
    int idNum; // Student ID number
    int creditHours; // Credit hours enrolled
    double gpa; // Current GPA
\};
void getData(Student *); // Function prototype
int main()
\{
    Student freshman;
    // Get the student data.
    cout << "Enter the following student data: \n";
    getData(\&freshman); // Pass the address of freshman.
    cout << "\nHere is the student data you entered:\n";
    // Now display the data stored in freshman
    cout << setprecision(3);
    cout << "Name: " << freshman.name << endl;
    cout << "ID Number: " << freshman.idNum << end1;
    cout << "Credit Hours: " << freshman.credithours << endl;
    cout << "GPA: " << freshman.gpa << endl;
    return 0;
\}
```

//********************************************************
// Definition of function getData. Uses a pointer to a *
// Student structure variable. The user enters student *
// information, which is stored in the variable. *
//**********************************************************
void getData(Student *s)
{
// Get the student name.
cout << "Student name: ";
getline(cin, s->name);
// Get the student ID number.
cout << "Student ID Number: ";
cin >> s->idNum;
// Get the credit hours enrolled.
cout << "Credit Hours Enrolled: ";
cin >> s->creditHours;
// Get the GPA.
cout << "Current GPA: ";
cin >> s->gpa;
}

```

\section*{Program Output with Example Input Shown in Bold}

Enter the following student data:
Student Name: Frank Smith Enter
Student ID Number: 4876 Enter
Credit Hours Enrolled: 12 Enter
Current GPA: 3.45 Enter
Here is the student data you entered:
Name: Frank Smith
ID Number: 4876
Credit Hours: 12
GPA: 3.45

\section*{Dynamically Allocating a Structure}

You can also use a structure pointer and the new operator to dynamically allocate a structure. For example, the following code defines a Circle pointer named cirPtr and dynamically allocates a Circle structure. Values are then stored in the dynamically allocated structure's members.
```

Circle *cirPtr = nullptr; // Define a Circle pointer
cirPtr = new Circle; // Dynamically allocate a Circle structure
cirPtr->radius = 10; // Store a value in the radius member
cirPtr->diameter = 20; // Store a value in the diameter member
cirPtr->area = 314.159; // Store a value in the area member

```

You can also dynamically allocate an array of structures. The following code shows an array of five Circle structures being allocated:
```

Circle *circles = nullptr;
circles = new Circle[5];
for (int count = 0; count < 5; count++)
{
cout << "Enter the radius for circle "
<< (count + 1) << ": ";
cin >> circles[count].radius;
}

```

\subsection*{11.10 Focus on Software Engineering: When to Use ., When to Use ->, and When to Use *}

Sometimes structures contain pointers as members. For example, the following structure declaration has an int pointer member:
```

struct GradeInfo
{
string name; // Student names
int *testScores; // Dynamically allocated array
float average; // Test average
};

```

It is important to remember that the structure pointer operator \((->)\) is used to dereference a pointer to a structure, not a pointer that is a member of a structure. If a program dereferences the testScores pointer in this structure, the indirection operator must be used. For example, assume that the following variable has been defined:
```

GradeInfo student1;

```

The following statement will display the value pointed to by the testScores member:
```

cout << *student1.testScores;

```

It is still possible to define a pointer to a structure that contains a pointer member. For instance, the following statement defines stPtr as a pointer to a GradeInfo structure:
```

GradeInfo *stPtr = nul1ptr;

```

Assuming stPtr points to a valid GradeInfo variable, the following statement will display the value pointed to by its testScores member:
```

cout << *stPtr->testScores;

```

In this statement, the * operator dereferences stPtr->testScores, while the \(->\) operator dereferences stPtr. It might help to remember that the following expression:
```

stPtr->testScores

```
is equivalent to
(*stPtr).testScores

So, the expression
```

*stPtr->testScores

```
is the same as
```

*(*stPtr).testScores

```

The awkwardness of this last expression shows the necessity of the \(->\) operator. Table 11-3 lists some expressions using the \({ }^{*},->\), and . operators and describes what each references.

\section*{Table 11-3 Structure Pointer Expressions}
\begin{tabular}{|c|c|}
\hline Expression & Description \\
\hline s->m & s is a structure pointer and m is a member. This expression accesses the m member of the structure pointed to by s. \\
\hline *a.p & \(a\) is a structure variable and \(p\), a pointer, is a member. This expression dereferences the value pointed to by \(p\). \\
\hline (*s).m & s is a structure pointer and m is a member. The * operator dereferences s , causing the expression to access the m member of the structure pointed to by s . This expression is the same as \(s->m\). \\
\hline *s->p & \(s\) is a structure pointer and \(p\), a pointer, is a member of the structure pointed to by s . This expression accesses the value pointed to by p . (The \(->\) operator dereferences \(s\) and the * operator dereferences \(p\).) \\
\hline * * \({ }^{\text {s }}\). p & \(s\) is a structure pointer and \(p\), a pointer, is a member of the structure pointed to by \(s\). This expression accesses the value pointed to by \(p\). (*s) dereferences \(s\) and the outermost * operator dereferences \(p\). The expression * \(s->p\) is equivalent. \\
\hline
\end{tabular}

\section*{Checkpoint}

Assume the following structure declaration exists for Questions 11.11-11.15:
```

struct Rectangle
{
int length;
int width;
};

```
11.11 Write a function that accepts a Rectangle structure as its argument and displays the structure's contents on the screen.
11.12 Write a function that uses a Rectangle structure reference variable as its parameter and stores the user's input in the structure's members.
11.13 Write a function that returns a Rectangle structure. The function should store the user's input in the members of the structure before returning it.
11.14 Write the definition of a pointer to a Rectangle structure.
11.15 Assume rptr is a pointer to a Rectangle structure. Which of the expressions, A, B , or C , is equivalent to the following expression:
```

    rptr->width
    A) *rptr.width
    B) (*rptr).width
    C) rptr.(*width)
    ```

\subsection*{11.11 Enumerated Data Types}

CONCEPT: An enumerated data type is a programmer-defined data type. It consists of values known as enumerators, which represent integer constants.

Using the enum key word, you can create your own data type and specify the values that belong to that type. Such a type is known as an enumerated data type. Here is an example of an enumerated data type declaration:
```

enum Day { MONDAY, TUESDAY, WEDNESDAY, THURSDAY, FRIDAY };

```

An enumerated type declaration begins with the key word enum, followed by the name of the type, followed by a list of identifiers inside braces, and is terminated with a semicolon. The example declaration creates an enumerated data type named Day. The identifiers MONDAY, TUESDAY, WEDNESDAY, THURSDAY, and FRIDAY, which are listed inside the braces, are known as enumerators. They represent the values that belong to the Day data type. Here is the general format of an enumerated type declaration:
enum TypeName \{ One or more enumerators \};
Note the enumerators are not enclosed in quotation marks; therefore, they are not strings. Enumerators must be legal C++ identifiers.

Once you have created an enumerated data type in your program, you can define variables of that type. For example, the following statement defines workDay as a variable of the Day type:
```

Day workDay;

```

Because workDay is a variable of the Day data type, we may assign any of the enumerators MONDAY, TUESDAY, WEDNESDAY, THURSDAY, or FRIDAY to it. For example, the following statement assigns the value WEDNESDAY to the workDay variable.
```

Day workDay = WEDNESDAY;

```

So just what are these enumerators MONDAY, TUESDAY, WEDNESDAY, THURSDAY, and FRIDAY? You can think of them as integer named constants. Internally, the compiler assigns integer values to the enumerators, beginning with 0 . The enumerator MONDAY is stored in memory as the number 0 , TUESDAY is stored in memory as the number 1 , WEDNESDAY is stored in memory as the number 2, and so forth. To prove this, look at the following code.
```

cout << MONDAY << endl << TUESDAY << endl
<< WEDNESDAY << endl << THURSDAY << endl
<< FRIDAY << endl;

```

This statement will produce the following output:

NOTE: When making up names for enumerators, it is not required that they be written in all uppercase letters. For example, we could have written the enumerators of the Days type as monday, tuesday, and so on. Because they represent constant values, however, many programmers prefer to write them in all uppercase letters. This is strictly a preference of style.

\section*{Assigning an Integer to an enum Variable}

Even though the enumerators of an enumerated data type are stored in memory as integers, you cannot directly assign an integer value to an enum variable. For example, assuming that workDay is a variable of the Day data type previously described, the following assignment statement is illegal:
```

workDay = 3; // Error!

```

Compiling this statement will produce an error message such as "Cannot convert int to Day." When assigning a value to an enum variable, you should use a valid enumerator. However, if circumstances require that you store an integer value in an enum variable, you can do so by casting the integer. Here is an example:
```

workDay = static_cast<Day>(3);

```

This statement will produce the same results as:
```

workDay = THURSDAY;

```

\section*{Assigning an Enumerator to an int Variable}

Although you cannot directly assign an integer value to an enum variable, you can directly assign an enumerator to an integer variable. For example, the following code will work just fine.
```

enum Day { MONDAY, TUESDAY, WEDNESDAY, THURSDAY, FRIDAY };
int x;
x = THURSDAY;
cout << x << end1;

```

When this code runs, it will display 3. You can also assign a variable of an enumerated type to an integer variable, as shown here:
```

Day workDay = FRIDAY;
int x = workDay;
cout << x << endl;

```

When this code runs, it will display 4.

\section*{Comparing Enumerator Values}

Enumerator values can be compared using the relational operators. For example, using the Day data type we have been discussing, the following expression is true:
```

FRIDAY > MONDAY

```

The expression is true because the enumerator FRIDAY is stored in memory as 4 and the enumerator MONDAY is stored as 0 . The following code will display the message "Friday is greater than Monday.":
```

if (FRIDAY > MONDAY)
cout << "Friday is greater than Monday. In";

```

You can also compare enumerator values with integer values. For example, the following code will display the message "Monday is equal to zero.":
```

if (MONDAY == O)
cout << "Monday is equal to zero.\n";

```

Let's look at a complete program that uses much of what we have learned so far. Program 11-9 uses the Day data type we have been discussing.

\section*{Program 11-9}
// This program demonstrates an enumerated data type.
\#include <iostream>
\#include <iomanip> using namespace std;
```

enum Day { MONDAY, TUESDAY, WEDNESDAY, THURSDAY, FRIDAY };

```
int main()
\{
    const int NUM_DAYS = 5; \(/ /\) The number of days
    double sales[NUM_DAYS]; // To hold sales for each day
    double total \(=0.0 ; \quad / /\) Accumulator
    int index; \(/ /\) Loop counter
    // Get the sales for each day.
    for (index = MONDAY; index <= FRIDAY; index++)
    \{
        cout << "Enter the sales for day "
                << index << ": ";
        cin >> sales[index];
    \}
    // Calculate the total sales.
    for (index = MONDAY; index <= FRIDAY; index++)
        total += sales[index];
    // Display the total.
    cout << "The total sales are \$" << setprecision(2)
        << fixed << total << endl;
    return 0;
\}

\section*{Program Output with Example Input Shown in Bold}
```

Enter the sales for day 0: 1525.00 Enter
Enter the sales for day 1: 1896.50 Enter
Enter the sales for day 2: 1975.63 Enter
Enter the sales for day 3: 1678.33 Enter
Enter the sales for day 4: 1498.52 Enter
The total sales are \$8573.98

```

\section*{Anonymous Enumerated Types}

Notice Program 11-9 does not define a variable of the Day data type. Instead, it uses the Day data type's enumerators in the for loops. The counter variable index is initialized to MONDAY (which is 0 ), and the loop iterates as long as index is less than or equal to FRIDAY (which is 4). When you do not need to define variables of an enumerated type, you can actually make the type anonymous. An anonymous enumerated type is simply one that does not have a name. For example, in Program 11-9 we could have declared the enumerated type as:
```

enum { MONDAY, TUESDAY, WEDNESDAY, THURSDAY, FRIDAY };

```

This declaration still creates the enumerators. We just can't use the data type to define variables, because the type does not have a name.

\section*{Using Math Operators to Change the Value of an enum Variable}

Even though enumerators are really integers, and enum variables really hold integer values, you can run into problems when trying to perform math operations with them. For example, look at the following code:
```

Day day1, day2; // Defines two Day variables.
day1 = TUESDAY; // Assign TUESDAY to day1.
day2 = day1 + 1; // ERROR! This wil1 not work!

```

The third statement causes a problem because the expression day \(1+1\) results in the integer value 2 . The assignment operator then attempts to assign the integer value 2 to the enum variable day2. Because C++ cannot implicitly convert an int to a Day, an error occurs. You can fix this by using a cast to explicitly convert the result to Day, as shown here:
```

day2 = static_cast<Day>(day1 + 1); // This works.

```

\section*{Using an enum Variable to Step through an Array's Elements}

Because enumerators are stored in memory as integers, you can use them as array subscripts. For example, look at the following code:
```

enum Day { MONDAY, TUESDAY, WEDNESDAY, THURSDAY, FRIDAY };
const int NUM_DAYS = 5;
double sales[NUM_DAYS];
sales[MONDAY] = 1525.0; // Stores 1525.0 in sales[0].
sales[TUESDAY] = 1896.5; // Stores 1896.5 in sales[1].
sales[WEDNESDAY] = 1975.63; // Stores 1975.63 in sales[2].
sales[THURSDAY] = 1678.33; // Stores 1678.33 in sales[3].
sales[FRIDAY] = 1498.52; // Stores 1498.52 in sales[4].

```

This code stores values in all five elements of the sales array. Because enumerator values can be used as array subscripts, you can use an enum variable in a loop to step through the elements of an array. However, using an enum variable for this purpose is not as straightforward as using an int variable. This is because you cannot use the ++ or -- operators directly on an enum variable. To understand what I mean, first look at the following code taken from Program 11-9:
```

for (index = MONDAY; index <= FRIDAY; index++)
{
cout << "Enter the sales for day "
<< index << ": ";
cin >> sales[index];
}

```

In this code, index is an int variable used to step through each element of the array. It is reasonable to expect that we could use a Day variable instead, as shown in the following code:
```

Day workDay; // Define a Day variable
// ERROR!!! This code will NOT work.
for (workDay = MONDAY; workDay <= FRIDAY; workDay++)
{
cout << "Enter the sales for day "
<< workDay << ": ";
cin >> sales[workDay];
}

```

Notice the for loop's update expression uses the ++ operator to increment workDay. Although this works fine with an int variable, the ++ operator cannot be used with an enum variable. Instead, you must convert workDay++ to an equivalent expression that will work. The expression workDay++ attempts to do the same thing as:
```

workDay = workDay + 1; // Good idea, but still won't work.

```

However, this still will not work. We have to use a cast to explicitly convert the expression workDay +1 to the Day data type, like this:
```

workDay = static_cast<Day>(workDay + 1);

```

This is the expression that we must use in the for loop instead of workDay++. The corrected for loop looks like this:
```

for (workDay = MONDAY; workDay <= FRIDAY;
workDay = static_cast<Day>(workDay + 1))
{
cout << "Enter the sales for day "
<< workDay << ": ";
cin >> sales[workDay];
}

```

Program 11-10 is a version of Program 11-9 that is modified to use a Day variable to step through the elements of the sales array.

\section*{Program 11-10}
```

// This program demonstrates an enumerated data type.
\#include <iostream>
\#include <iomanip>
using namespace std;
enum Day { MONDAY, TUESDAY, WEDNESDAY, THURSDAY, FRIDAY };
int main()
{
const int NUM_DAYS = 5; // The number of days
double sales[NUM_DAYS]; // To hold sales for each day
double total = 0.0; // Accumulator
Day workDay; // Loop counter
// Get the sales for each day.
for (workDay = MONDAY; workDay <= FRIDAY;
workDay = static_cast<Day>(workDay + 1))
{
cout << "Enter the sales for day "
<< workDay << ": ";
cin >> sales[workDay];
}
// Calculate the total sales.
for (workDay = MONDAY; workDay <= FRIDAY;
workDay = static_cast<Day>(workDay + 1))
total += sales[workDay];
// Display the total.
cout << "The total sales are \$" << setprecision(2)
<< fixed << total << endl;
return 0;
}

```

\section*{Program Output with Example Input Shown in Bold}
```

Enter the sales for day 0: 1525.00 Enter
Enter the sales for day 1: 1896.50 Enter
Enter the sales for day 2: 1975.63 Enter
Enter the sales for day 3: 1678.33 Enter
Enter the sales for day 4: 1498.52 Enter
The total sales are \$8573.98

```

\section*{Using Enumerators to Output Values}

As you have already seen, sending an enumerator to cout causes the enumerator's integer value to be displayed. For example, assuming we are using the Day type previously described, the following statement displays 0 :
```

cout << MONDAY << end1;

```

If you wish to use the enumerator to display a string such as "Monday," you'll have to write code that produces the desired string. For example, in the following code, assume workDay is a Day variable that has been initialized to some value. The switch statement displays the name of a day, based upon the value of the variable.
```

switch(workDay)
{
case MONDAY : cout << "Monday";
break;
case TUESDAY : cout << "Tuesday";
break;
case WEDNESDAY : cout << "Wednesday";
break;
case THURSDAY : cout << "Thursday";
break;
case FRIDAY : cout << "Friday";
}

```

Program 11-11 shows this type of code used in a function. Instead of asking the user to enter the sales for day 0 , day 1 , and so forth, it displays the names of the days.

\section*{Program 11-11}
```

// This program demonstrates an enumerated data type.
\#include <iostream>
\#include <iomanip>
using namespace std;
enum Day { MONDAY, TUESDAY, WEDNESDAY, THURSDAY, FRIDAY };
// Function prototype
void displayDayName(Day);
int main()
{
const int NUM_DAYS = 5; // The number of days
double sales[NUM_DAYS]; // To hold sales for each day
double total = 0.0; // Accumulator
Day workDay; // Loop counter
// Get the sales for each day.
for (workDay = MONDAY; workDay <= FRIDAY;
workDay = static_cast<Day>(workDay + 1))
{
cout << "Enter the sales for day ";
displayDayName(workDay);
cout << ": ";
cin >> sales[workDay];
}

```
```

    // Calculate the total sales.
    for (workDay = MONDAY; workDay <= FRIDAY;
        workDay = static_cast<Day>(workDay + 1))
        total += sales[workDay];
    // Display the total.
    cout << "The total sales are $" << setprecision(2)
        << fixed << total << endl;
    return 0;
    }
//***********************************************************
// Definition of the displayDayName function
// This function accepts an argument of the Day type and
// displays the corresponding name of the day.
//**********************************************************
void displayDayName(Day d)
{
switch(d)
{
case MONDAY : cout << "Monday";
break;
case TUESDAY : cout << "Tuesday";
break;
case WEDNESDAY : cout << "Wednesday";
break;
case THURSDAY : cout << "Thursday";
break;
case FRIDAY : cout << "Friday";
}
}

```

Program Output with Example Input Shown in Bold
```

Enter the sales for Monday: 1525.00 Enter
Enter the sales for Tuesday: 1896.50 Enter
Enter the sales for Wednesday: 1975.63 Enter
Enter the sales for Thursday: 1678.33 Enter
Enter the sales for Friday: 1498.52 Enter
The total sales are \$8573.98

```

\section*{Specifying Integer Values for Enumerators}

By default, the enumerators in an enumerated data type are assigned the integer values 0 , 1,2 , and so forth. If this is not appropriate, you can specify the values to be assigned, as in the following example:
```

enum Water { FREEZING = 32, BOILING = 212 };

```

In this example, the FREEZING enumerator is assigned the integer value 32, and the BOILING enumerator is assigned the integer value 212. Program 11-12 demonstrates how this enumerated type might be used.

\section*{Program 11-12}
```

// This program demonstrates an enumerated data type.
\#include <iostream>
\#include <iomanip>
using namespace std;
int main()
{
enum Water { FREEZING = 32, BOILING = 212 };
int waterTemp; // To hold the water temperature
cout << "Enter the current water temperature: ";
cin >> waterTemp;
if (waterTemp <= FREEZING)
cout << "The water is frozen.\n";
else if (waterTemp >= BOILING)
cout << "The water is boiling.\n";
else
cout << "The water is not frozen or boiling.\n";
return 0;
}

```

\section*{Program Output with Example Input Shown in Bold}
```

Enter the current water temperature: 10 Enter
The water is frozen.

```

\section*{Program Output with Example Input Shown in Bold}

Enter the current water temperature: \(\mathbf{3 0 0}\) Enter The water is boiling.

\section*{Program Output with Example Input Shown in Bold}
```

Enter the current water temperature: 92 Enter

```
The water is not frozen or boiling.

If you leave out the value assignment for one or more of the enumerators, it will be assigned a default value. Here is an example:
```

enum Colors { RED, ORANGE, YELLOW = 9, GREEN, BLUE };

```

In this example, the enumerator RED will be assigned the value 0 , ORANGE will be assigned the value 1 , YELLOW will be assigned the value 9 , GREEN will be assigned the value 10 , and BLUE will be assigned the value 11 .

\section*{Enumerators Must Be Unique within the Same Scope}

Enumerators are identifiers just like variable names, named constants, and function names. As with all identifiers, they must be unique within the same scope. For example, an error will result if both of the following enumerated types are declared within the same scope. In the following example, the reason is that ROOSEVELT is declared twice.
```

enum Presidents { MCKINLEY, ROOSEVELT, TAFT };
enum VicePresidents { ROOSEVELT, FAIRBANKS, SHERMAN }; // Error!

```

The following declarations will also cause an error if they appear within the same scope.
```

enum Status { OFF, ON };
const int OFF = 0; // Error!

```

\section*{Declaring the Type and Defining the Variables in One Statement}

The following code uses two lines to declare an enumerated data type and define a variable of the type:
```

enum Car { PORSCHE, FERRARI, JAGUAR };
Car sportsCar;

```

C++ allows you to declare an enumerated data type and define one or more variables of the type in the same statement. The previous code could be combined into the following statement:
```

enum Car { PORSCHE, FERRARI, JAGUAR } sportsCar;

```

The following statement declares the Car data type and defines two variables: myCar and yourCar.
```

enum Car { PORSCHE, FERRARI, JAGUAR } myCar, yourCar;

```

\section*{Using Strongly Typed enums in C++ 11}

Earlier, we mentioned that you cannot have multiple enumerators with the same name, within the same scope. In C++ 11, you can use a new type of enum, known as a strongly typed enum (also known as an enum class), to get around this limitation. Here are two examples of a strongly typed enum declaration:
```

enum class Presidents { MCKINLEY, ROOSEVELT, TAFT };
enum class VicePresidents { ROOSEVELT, FAIRBANKS, SHERMAN };

```

These statements declare two strongly typed enums: Presidents and VicePresidents. Notice they look like regular enum declarations, except the word class appears after enum. Although both enums contain the same enumerator (ROOSEVELT), these declarations will compile without an error.

When you use a strongly typed enumerator, you must prefix the enumerator with the name of the enum, followed by the :: operator. Here are two examples:
```

Presidents prez = Presidents::ROOSEVELT;
VicePresidents vp = VicePresidents::ROOSEVELT;

```

The first statement defines a Presidents variable named prez, and initializes it with the Presidents::ROOSEVELT enumerator. The second statement defines a VicePresidents variable named vp , and initializes it with the VicePresidents:: ROOSEVELT enumerator. Here is an example of an if statement that compares the prez variable with an enumerator:
```

if (prez == Presidents::ROOSEVELT)
cout << "Roosevelt is president!\n";

```

Strongly typed enumerators are stored as integers like regular enumerators. However, if you want to retrieve a strongly typed enumerator's underlying integer value, you must use a cast operator. Here is an example:
```

int x = static_cast<int>(Presidents::ROOSEVELT);

```

This statement assigns the underlying integer value of the Presidents: :ROOSEVELT enumerator to the variable x . Here is another example:
```

cout << static_cast<int>(Presidents::TAFT) << end1
<< static_cast<int>(Presidents::MCKINLEY) << endl;

```

This statement displays the integer values for the Presidents::TAFT and the Presidents: :MCKINLEY enumerators.

When you declare a strongly typed enum, you can optionally specify any integer data type as the underlying type. You simply write a colon (:) after the enum name, followed by the desired data type. For example, the following statement declares an enum that uses the char data type for its enumerators:
```

enum class Day : char { MONDAY, TUESDAY, WEDNESDAY, THURSDAY, FRIDAY };

```

The following statement shows another example. This statement declares an enum named Water that uses unsigned as the data type of its enumerators. Additionally, values are assigned to the enumerators.
```

enum class Water : unsigned { FREEZING = 32, BOILING = 212 };

```

\section*{Checkpoint}
11.16 Look at the following declaration:
```

enum Flower { ROSE, DAISY, PETUNIA };

```

In memory, what value will be stored for the enumerator ROSE? For DAISY? For PETUNIA?
11.17 What will the following code display?
```

enum { HOBBIT, ELF = 7, DRAGON };
cout << HOBBIT << " " << ELF << " " << DRAGON << endl;

```
11.18 Does the enumerated data type declared in Checkpoint Question 11.17 have a name, or is it anonymous?
11.19 What will the following code display?
```

enum Letters { Z, Y, X };
if (Z > X)
cout << "Z is greater than X. \n";
else
cout << "Z is not greater than X. \n";

```
11.20 Will the following code cause an error, or will it compile without any errors? If it causes an error, rewrite it so it compiles.
```

enum Color { RED, GREEN, BLUE };

```
Color c;
c = 0;
11.21 Will the following code cause an error, or will it compile without any errors? If it causes an error, rewrite it so it compiles.
enum Color \{ RED, GREEN, BLUE \};
Color c = RED;
c++;

NOTE: For an additional example of this chapter's topics, see the High Adventure Travel Part 2 Case Study on the Computer Science Portal at www.pearsonglobaleditions. com/gaddis.

\section*{Review Questions and Exercises}

\section*{Short Answer}
1. What is a primitive data type?
2. Does a structure declaration cause a structure variable to be created?
3. Both arrays and structures are capable of storing multiple values. What is the difference between an array and a structure?
4. Look at the following structure declaration:
struct Point
\{
int \(x\);
int \(y\);
\};
Write statements that
A) define a Point structure variable named center.
B) assign 12 to the \(x\) member of center.
C) assign 7 to the \(y\) member of center.
D) display the contents of the \(x\) and \(y\) members of center.
5. Look at the following structure declaration:
struct FullName
\{
string lastName;
string middleName;
string firstName;
\};
Write statements that
A) define a Ful 1 Name structure variable named info.
B) assign your last, middle, and first name to the members of the info variable.
C) display the contents of the members of the info variable.
6. Look at the following code:
struct PartData
\{
string partName;
int idNumber;
\};
PartData inventory[100];

Write a statement that displays the contents of the partName member of element 49 of the inventory array.
7. Look at the following code:
```

struct Town
{
string townName;
string countyName;
double population;
double elevation;
};
Town t = { "Canton", "Haywood", 9478 };

```
A) What value is stored in t.townName?
B) What value is stored in \(t\).countyName?
C) What value is stored in \(t\).population?
D) What value is stored in t.elevation?
8. Look at the following code:
```

structure Rectangle
{
int length;
int width;
};
Rectangle *r = nullptr

```

Write statements that
A) dynamically allocate a Rectangle structure variable and use \(r\) to point to it.
B) assign 10 to the structure's length member and 14 to the structure's width member.
9. Which declaration will you prefer from the following and why?
enum TruthVal \{ TRUE, FALSE \}; enum TruthVal \{ FALSE, TRUE \};
10. Look at the following declaration:
enum Person \{ BILL, JOHN, CLAIRE, BOB \};
Person p;
Indicate whether each of the following statements or expressions is valid or invalid.
A) \(p=B O B\);
B) \(p++\);
C) BILL > BOB
D) \(p=0\);
E) int \(\mathrm{x}=\mathrm{BILL}\);
F) \(\mathrm{p}=\) static_cast<Person>(3);
G) cout << CLAIRE << endl;

\section*{Fill-in-the-Blank}
11. Before a structure variable can be created, the structure must be \(\qquad\) .
12. When accessing a structure member, the variable to the left of the dot operator is \(\qquad\) .
13. A(n) \(\qquad\) data type does not have a name.
14. The data members of \(a(n)\) \(\qquad\) occupy the same memory location.
15. In the definition of a structure variable, the \(\qquad\) is placed before the variable name, just like the data type of a regular variable is placed before its name.
16. The \(\qquad\) operator is used to access structure members from a structure variable.

\section*{Algorithm Workbench}
17. The structure Car is declared as follows:
```

struct Car
{
string carMake;
string carModel;
int yearMode1;
double cost;
};

```

Write a definition statement that defines a Car structure variable initialized with the following data:
Make: Ford
Model: Mustang
Year Model: 1968
Cost: \$20,000
18. Define an array of 25 of the Car structure variables (the structure is declared in Question 17).
19. Define an array of 35 of the Car structure variables. Initialize the first three elements with the following data:
\begin{tabular}{llll} 
Make & Model & Year & Cost \\
Ford & Taurus & 1997 & \(\$ 21,000\) \\
Honda & Accord & 1992 & \(\$ 11,000\) \\
Lamborghini & Countach & 1997 & \(\$ 200,000\)
\end{tabular}
20. Write a loop that will step through the array you defined in Question 19, displaying the contents of each element.
21. Declare a structure named TempScale, with the following members:
fahrenheit: a double
centigrade: a double
Next, declare a structure named Reading, with the following members:
```

windSpeed: an int
humidity: a double
temperature: a TempScale structure variable
Next, define a Reading structure variable.

```
22. Write statements that will store the following data in the variable you defined in Problem 21:
Wind Speed: 37 mph
Humidity: 32\%
Fahrenheit temperature: 32 degrees
Centigrade temperature: 0 degrees
23. Write a function called showReading. It should accept a Reading structure variable (see Problem 21) as its argument. The function should display the contents of the variable on the screen.
24. Write a function called findReading. It should use a Reading structure reference variable (see Problem 21) as its parameter. The function should ask the user to enter values for each member of the structure.
25. Write a function called getReading, which returns a Reading structure (see Problem 21). The function should ask the user to enter values for each member of a Reading structure, then return the structure.
26. Write a function called recordReading. It should use a Reading structure pointer variable (see Problem 21) as its parameter. The function should ask the user to enter values for each member of the structure pointed to by the parameter.
27. What is the purpose of the following expression that has used nested structures?
employee.address.postcode = 9909;
28. Look at the following statement:
enum Shape3D \{ SPHERE, CUBE, CYLINDER \};
A) What are the enumerators and what are their default values?
B) How can you assign values of the enumerators to the number of surfaces that it has?
C) Write code to declare three Shape3D variables item1, item2, and item3, and assign them the permissible values.
29. Declare an enumerated data type Shape that has three enumerators CIRCLE, SQUARE, and TRIANGLE, and one Shape variable in a single statement.

\section*{True or False}
30. T F A semicolon is required after the closing brace of a structure declaration.
31. T F Abstract data types are defined as the basic parts of a computer language.
32. T F The contents of a structure variable can be displayed by passing the structure variable to the cout object.
33. T F Structure member variables may be initialized in the declaration of the structure.
34. T F In a structure variable's initialization list, you do not have to provide initializers for all the members.
35. T F A structure and a union can be used interchangeably.
36. T F The following expression refers to element 5 in the array carInfo: carInfo. model [5]
37. T F It is possible to dynamically allocate an array of structures.
38. T F A structure definition allocates space in memory for all its members.
39. T F Nested structure implies a structure variable within another structured variable.
40. T F An entire structure may not be passed to a function as an argument.
41. T F A function may return a pointer to a structure variable.
42. T F When a function returns a structure, it is always necessary for the function to have a local structure variable to hold the member values that are to be returned.
43. T F The indirection operator has higher precedence than the dot operator.
44. T F The structure pointer operator does not automatically dereference the structure pointer on its left.

\section*{Find the Errors}

Each of the following declarations, programs, and program segments has errors. Locate as many as you can.
```

45. Struct myStruct
{
int x;
float y;
};
46. {
int number[10] = { 1, 2, 3, 4, 5, 6, 7, 8, 9, 0};
int total;
}
47. struct TwoVals
{
int a, b;
};
int main ()
{
TwoVals.a = 10;
TwoVals.b = 20;
return 0;
}
48. \#include <iostream>
using namespace std;
struct ThreeVals
{
int a, b, c;
};
int main()
{
ThreeVals vals = {1, 2, 3};
cout << vals << endl;
return 0;
}
```
```

49. \#include <iostream>
\#include <string>
using namespace std;
struct names
{
string first;
string last;
};
int main ()
{
names customer = "Smith", "Orley";
cout << names.first << endl;
cout << names.last << endl;
return 0;
}
50. struct FourVals
{
int a, b, c, d;
};
int main ()
{
FourVals nums = {1, 2, , 4};
return 0;
}
51. struct TwoVals
{
int a;
int b;
};
TwoVals getVals()
{
TwoVals.a = TwoVals.b = 0;
}
52. struct ThreeVals
{
int a, b, c;
};
int main ()
{
TwoVals s, *sptr = nullptr;
sptr = \&s;
*sptr.a = 1;
return 0;
}
```

\section*{Programming Challenges}

\section*{1. Movie Data}

Write a program that uses a structure named MovieData to store the following information about a movie:

Title
Director
Year Released
Running Time (in minutes)
The program should create two MovieData variables, store values in their members, and pass each one, in turn, to a function that displays the information about the movie in a clearly formatted manner.

\section*{2. Movie Profit}

Modify the program written for Programming Challenge 1 (Movie Data) to include two additional members that hold the movie's production costs and first-year revenues. Modify the function that displays the movie data to display the title, director, release year, running time, and first year's profit or loss.
3. Report on Earthquakes

The National Earthquake Information Center wants to record data on three earthquakes that have hit the country in the last two years. The department needs to store the following data about each earthquake:

Name of earthquake
Location of earthquake
Year
Magnitude in Richter scale
Fatalities
Write a program that declares a structure with fields to store the above data. The program should declare three variables of the above structure to represent the three earthquakes. The user should be asked to input the particulars of each earthquake. It should then display an analysis on the earthquakes. The particulars that should be shown in the analysis are:
- Total fatalities due to the three earthquakes.
- The average magnitude of the three earthquakes.
- Name and magnitude of the earthquake that had maximum magnitude.
- Name of the earthquake that caused maximum fatalities.

\section*{4. Weather Statistics}

Write a program that uses a structure to store the following weather data for a particular month:

Total Rainfall
High Temperature
Low Temperature
Average Temperature
The program should have an array of 12 structures to hold weather data for an entire year. When the program runs, it should ask the user to enter data for each month. (The average temperature should be calculated.) Once the data are entered for all the
months, the program should calculate and display the average monthly rainfall, the total rainfall for the year, the highest and lowest temperatures for the year (and the months they occurred in), and the average of all the monthly average temperatures.
Input Validation: Only accept temperatures within the range between -100 and +140 degrees Fahrenheit.

\section*{5. Weather Statistics Modification}

Modify the program that you wrote for Programming Challenge 4 (weather statistics) so it defines an enumerated data type with enumerators for the months (JANUARY, FEBRUARY, so on). The program should use the enumerated type to step through the elements of the array.

\section*{6. Popularity Score}

Write a program that stores the following data about a quote in a structure:
The originator of the quote
The quote itself
The number of likes the quote has received
Write a function that, given an array of quotes and the length of that array, calculates both the total number of likes and the average number of likes. Demonstrate the function in a program that asks the user to enter the data for seven quotes. The program should show a table that lists only those quotes that are more popular than the average quote and that shows the percentage of likes each received.
Input Validation: Do not accept negative values for the number of likes.

\section*{7. Computer Configurations}

Write a program that uses a structure to store the following data about a computer:
The clock speed of the processor
The number of CPU cores
The amount of RAM
The size of the hard disk
The benchmark score (higher is faster)
The price of the computer
The program should have a menu-driven interface with the options to add a new computer configuration, to change the price of an existing configuration, and to show the full data of all computers. The user selects a configuration by entering its number.
Input Validation: Do not accept negative values for the benchmark score or the price. When entering the number of a configuration, accept only existing numbers.

\section*{8. Search Function for Computers}

Add a function to Programming Challenge 7 (Computer Configurations) that allows the user to search for a computer that meets a minimum specification and that remains within budget. The function should accept a minimum value for the benchmark score and a maximum value for the price as arguments, and display all suitable configurations. If no configurations match, a message saying so should be displayed.

\section*{9. Speakers' Bureau}

Write a program that keeps track of a speakers' bureau. The program should use a structure to store the following data about a speaker:

Name
Telephone Number
Speaking Topic
Fee Required
The program should use an array of at least 10 structures. It should let the user enter data into the array, change the contents of any element, and display all the data stored in the array. The program should have a menu-driven user interface.
Input Validation: When the data for a new speaker is entered, be sure the user enters data for all the fields. No negative amounts should be entered for a speaker's fee.

\section*{10. Search Function for the Speakers' Bureau Program}

Add a function to Programming Challenge 9 (Speakers' Bureau) that allows the user to search for a speaker on a particular topic. It should accept a key word as an argument then search the array for a structure with that key word in the Speaking Topic field. All structures that match should be displayed. If no structure matches, a message saying so should be displayed.
11. Comparison of Date and Time

Write a program that has a dateTime structure to store the following particulars about date and time:
Year
Month
Date
Hours
Minutes
Seconds

The program should declare two dateTime variables of the above structure and ask the user to input data on the date and time of two different instances. The program should pass these structure variables as arguments to a function. The function should determine the date (and not time) that comes earlier between the two arguments. If both dates are same, the function displays a message "Identical dates" and returns any of the arguments; otherwise it should return the date that comes earlier.
Input Validation: Do not accept negative values for year. Accept values for month only within the range 1 - 12. Accept hours between 0 and 23, minutes between 0 and 59, and seconds between 0 and 59.

\section*{12. Restaurant Top Dishes}

A brochure for a region popular with tourists gives all the restaurants in the region the opportunity to advertise their most popular dishes. Write a program that uses a structure to store the following data:
\begin{tabular}{ll}
\hline Member Name & Description \\
\hline Name & Restaurant name \\
Description & Short description of the restaurant \\
Menus & Pointer to an array of three menu items \\
AveragePrice & The average price of the items \\
VegetarianOptions & A Boolean indicating whether vegetarian dishes are available \\
\hline
\end{tabular}

The Menus member in this structure should point to an array of length 3 that will hold different menu items. The MenuItem is itself a simple structure that holds three members, the name of the dish (a string), a link to a picture of the dish (a string), and the price (a double).
The program should keep a list of restaurants and their menus. It should first ask the user for the number of restaurants. It should then ask the user to input all data. For each restaurant, it should first ask the name and the description of the restaurant, and whether it offers vegetarian dishes. Next the user must input the data of the three most popular menu items. The average price should be calculated and stored in the corresponding member of each restaurant structure.
Once everything is calculated, the program should ask the user for a price range (minimum and maximum price) and display all the restaurants whose average price falls in that price range.
Input Validation: Be sure all the data for each restaurant and menu item is entered. Do not accept negative numbers for the price of a menu item.

\section*{13. Full Restaurant Menu}

Modify the solution of Programming Challenge 12 (Restaurant Top Dishes) such that each restaurant can store its full menu. The Restaurant structure should also be expanded with the following data:
\begin{tabular}{ll}
\hline Member Name & Description \\
\hline MenuSize & The size of the menu \\
Minimum & The price of the cheapest menu item \\
Maximum & The price of the most expensive menu item \\
\hline
\end{tabular}

The Menus member in the restaurant structure should be modified such that it now points to a dynamically allocated array that will hold the different menu items. Because the Menus member is a dynamically allocated array, the number of menu items can now be different for each restaurant. The MenuItem structure should be expanded to hold a member variable that indicates whether a dish is vegetarian.
The program should still first ask the user for the number of restaurants and dynamically allocate an array of structures to store all the restaurants. For each restaurant, it should now only ask the name and the description of the restaurant. Next the program should ask for the number of items on the menu. It should allocate an array of structures for the specified number of menu items and let the user enter all the menu items for that restaurant. Instead of only calculating the average price, the minimum and maximum price should also be calculated and stored in the corresponding members of each structure. The Boolean that indicates whether the restaurant offers vegetarian options can be derived from the menu items of the restaurant. A restaurant offers vegetarian options if at least one menu item is vegetarian.

Once everything has been calculated, the program should now ask the user for a single price and display all the restaurants where the price chosen by the user is between the minimum and maximum price of the restaurant.
Input Validation: Be sure all the data for each restaurant and menu item is entered. Do not accept negative numbers for the price of a menu item.

\section*{14. Inventory Bins}

Write a program that simulates inventory bins in a warehouse. Each bin holds a number of the same type of parts. The program should use a structure that keeps the following data:

Description of the part kept in the bin
Number of parts in the bin
The program should have an array of 10 bins, initialized with the following data:
\begin{tabular}{ll}
\hline Part Description & Number of Parts in the Bin \\
\hline Valve & 10 \\
Bearing & 5 \\
Bushing & 15 \\
Coupling & 21 \\
Flange & 7 \\
Gear & 5 \\
Gear Housing & 5 \\
Vacuum Gripper & 25 \\
Cable & 18 \\
Rod & 12 \\
\hline
\end{tabular}

The program should have the following functions:
AddParts-increases a specific bin's part count by a specified number.
RemoveParts-decreases a specific bin's part count by a specified number.
When the program runs, it should repeat a loop that performs the following steps: The user should see a list of what each bin holds and how many parts are in each bin. The user can choose to either quit the program or select a bin. When a bin is selected, the user can either add parts to it or remove parts from it. The loop then repeats, showing the updated bin data on the screen.
Input Validation: No bin can hold more than 30 parts, so don't let the user add more than a bin can hold. Also, don't accept negative values for the number of parts being added or removed.

12.9 Random-Access Files
12.10 Opening a File for Both Input andOutput

\subsection*{12.1 File Operations}

CONCEPT: A file is a collection of data that is usually stored on a computer's disk. Data can be saved to files and then later reused.

Almost all real-world programs use files to store and retrieve data. Here are a few examples of familiar software packages that use files extensively:
- Word Processors: Word processing programs are used to write letters, memos, reports, and other documents. The documents are then saved in files so they can be edited and reprinted.
- Database Management Systems: DBMSs are used to create and maintain databases. Databases are files that contain large collections of data, such as payroll records, inventories, sales statistics, and customer records.
- Spreadsheets: Spreadsheet programs are used to work with numerical data. Numbers and mathematical formulas can be inserted into the rows and columns of the spreadsheet. The spreadsheet can then be saved to a file for later use.
- Compilers: Compilers translate the source code of a program, which is saved in a file, into an executable file. Throughout the previous chapters of this book you have created many C++ source files and compiled them to executable files.
Chapter 5 provided enough information for you to write programs that perform simple file operations. This chapter covers more advanced file operations and focuses primarily
on the fstream data type. As a review, Table 12-1 compares the ifstream, ofstream, and fstream data types. All of these data types require the <fstream> header file.

Table 12-1 File Stream Data Types
\begin{tabular}{ll}
\hline Data Type & Description \\
\hline ifstream & \begin{tabular}{l} 
Input File Stream. This data type can be used only to read data from files into \\
memory.
\end{tabular} \\
ofstream & Output File Stream. This data type can be used to create files and write data to them. \\
fstream & \begin{tabular}{l} 
File Stream. This data type can be used to create files, write data to them, and read \\
data from them.
\end{tabular}
\end{tabular}

\section*{Using the fstream Data Type}

You define an fstream object just as you define objects of other data types. The following statement defines an fstream object named dataFile:
```

fstream dataFile;

```

As with ifstream and ofstream objects, you use an fstream object's open function to open a file. An fstream object's open function requires two arguments, however. The first argument is a string containing the name of the file. The second argument is a file access flag that indicates the mode in which you wish to open the file. Here is an example:
```

dataFile.open("info.txt", ios::out);

```

The first argument in this function call is the name of the file, info.txt. The second argument is the file access flag ios: :out. This tells C++ to open the file in output mode. Output mode allows data to be written to a file. The following statement uses the ios: in access flag to open a file in input mode, which allows data to be read from the file.
```

dataFile.open("info.txt", ios::in);

```

There are many file access flags, as listed in Table 12-2.
Table 12-2 File Access Flags
\begin{tabular}{ll}
\hline File Access Flag & Meaning \\
\hline ios: :app & \begin{tabular}{l} 
Append mode. If the file already exists, its contents are preserved and all \\
output is written to the end of the file. By default, this flag causes the file to \\
be created if it does not exist.
\end{tabular} \\
ios: :ate & \begin{tabular}{l} 
If the file already exists, the program goes directly to the end of it. Output \\
may be written anywhere in the file.
\end{tabular} \\
ios: : binary & \begin{tabular}{l} 
Binary mode. When a file is opened in binary mode, data are written to or \\
read from it in pure binary format. (The default mode is text.)
\end{tabular} \\
ios: : in & \begin{tabular}{l} 
Input mode. Data will be read from the file. If the file does not exist, it will \\
not be created, and the open function will fail.
\end{tabular} \\
ios: :out & \begin{tabular}{l} 
Output mode. Data will be written to the file. By default, the file's contents \\
will be deleted if it already exists.
\end{tabular} \\
ios: :trunc & \begin{tabular}{l} 
If the file already exists, its contents will be deleted (truncated). This is the \\
default mode used by ios: :out.
\end{tabular} \\
\hline
\end{tabular}

Several flags may be used together if they are connected with the I operator. For example, assume dataFile is an fstream object in the following statement:
```

dataFile.open("info.txt", ios::in | ios::out);

```

This statement opens the file info.txt in both input and output modes. This means data may be written to and read from the file.

NOTE: When used by itself, the ios: : out flag causes the file's contents to be deleted if the file already exists. When used with the ios: : in flag, however, the file's existing contents are preserved. If the file does not already exist, it will be created.

The following statement opens the file in such a way that data will only be written to its end:
```

dataFile.open("info.txt", ios::out | ios::app);

```

By using different combinations of access flags, you can open files in many possible modes.
Program 12-1 uses an fstream object to open a file for output, then writes data to the file.

\section*{Program 12-1}
```

// This program uses an fstream object to write data to a file.
\#include <iostream>
\#include <fstream>
using namespace std;
int main()
{
fstream dataFile;
cout << "Opening file...\n";
dataFile.open("demofile.txt", ios::out); // Open for output
cout << "Now writing data to the file.\n";
dataFile << "Jones\n"; // Write line 1
dataFile << "Smith\n"; // Write line 2
dataFile << "Willis\n"; // Write line 3
dataFile << "Davis\n"; // Write line 4
dataFile.close(); // Close the file
cout << "Done.\n";
return 0;
}

```

\section*{Program Output}

Opening file
Now writing data to the file.
Done.

\section*{Output to File demofile.txt}

Jones
Smith
Willis
Davis

The file output is shown for Program 12-1 the way it would appear if the file contents were displayed on the screen. The In characters cause each name to appear on a separate line. The actual file contents, however, appear as a stream of characters as shown in Figure 12-1.

\section*{Figure 12-1 File contents}
\begin{tabular}{|c|c|c|c|c|c|c|c|c|c|c|c|c|c|c|}
\hline J & o & n & e & s & \(\ln\) & s & m & i & t & h & \(\ln\) & W & i & l \\
\hline
\end{tabular}
\begin{tabular}{|c|c|c|c|c|c|c|c|c|c|c|}
\hline I & i & s & \(\ln\) & D & a & v & i & s & \(\ln\) & \(<\) EOF \(>\) \\
\hline
\end{tabular}

As you can see from the figure, In characters are written to the file along with all the other characters. The characters are added to the file sequentially, in the order they are written by the program. The very last character is an end-of-file marker. It is a character that marks the end of the file, and is automatically written when the file is closed. (The actual character used to mark the end of a file depends upon the operating system being used. It is always a nonprinting character. For example, some systems use control-Z, which is ASCII code 26.)

Program 12-2 is a modification of Program 12-1 that further illustrates the sequential nature of files. The file is opened, two names are written to it, and it is closed. The file is then reopened by the program in append mode (with theios::app access flag). When a file is opened in append mode, its contents are preserved, and all subsequent output is appended to the file's end. Two more names are added to the file before it is closed and the program terminates.

\section*{Program 12-2}
```

// This program writes data to a file, closes the file,
// then reopens the file and appends more data.
\#include <iostream>
\#include <fstream>
using namespace std;
int main()
{
ofstream dataFile;
cout << "Opening file...\n";
// Open the file in output mode.
dataFile.open("demofile.txt", ios::out);
cout << "Now writing data to the file.\n";
dataFile << "Jones\n"; // Write line 1
dataFile << "Smith\n"; // Write line 2
cout << "Now closing the file.\n";
dataFile.close(); // Close the file
cout << "Opening the file again...\n";
// Open the file in append mode.
dataFile.open("demofile.txt", ios::out | ios::app);
cout << "Writing more data to the file.\n";
dataFile << "Willis\n"; // Write line 3
dataFile << "Davis\n"; // Write line 4
cout << "Now closing the file.\n";
dataFile.close(); // Close the file

```
```

28
29 cout << "Done.\n";
30 return 0;
31 }

```
Output to File demofile.txt
Jones
Smith
Willis
Davis

The first time the file is opened, the names are written as shown in Figure 12-2.
Figure 12-2 Original file contents
\begin{tabular}{|c|c|c|c|c|c|c|c|c|c|c|c|c|}
\hline J & o & n & e & s & \(\ln\) & s & m & i & t & h & \(\ln\) & <EOF \(>\) \\
\hline
\end{tabular}

The file is closed, and an end-of-file character is automatically written. When the file is reopened, the new output is appended to the end of the file, as shown in Figure 12-3.

Figure 12-3 New data appended to the file
\begin{tabular}{|c|c|c|c|c|c|c|c|c|c|c|c|c|c|c|}
\hline J & o & n & e & s & \(\ln\) & s & m & i & t & h & \(\ln\) & W & i & I \\
\hline
\end{tabular}
\begin{tabular}{|c|c|c|c|c|c|c|c|c|c|c|}
\hline I & i & s & \(\ln\) & D & a & v & i & s & \(\ln\) & KEOF \\
\hline
\end{tabular}

NOTE: If the ios: :out flag had been alone, without ios::app the second time the file was opened, the file's contents would have been deleted. If this had been the case, the names Jones and Smith would have been erased, and the file would only have contained the names Willis and Davis.

\section*{File Open Modes with ifstream and ofstream Objects}

The ifstream and ofstream data types each have a default mode in which they open files. This mode determines the operations that may be performed on the file and what happens if the file that is being opened already exists. Table 12-3 describes each data type's default open mode.

Table 12-3 Default Open Mode
\begin{tabular}{ll}
\hline File Type & Default Open Mode \\
\hline ofstream & \begin{tabular}{l} 
The file is opened for output only. Data may be written to the file, but not read \\
from the file. If the file does not exist, it is created. If the file already exists, its \\
contents are deleted (the file is truncated).
\end{tabular} \\
ifstream & \begin{tabular}{l} 
The file is opened for input only. Data may be read from the file, but not written \\
to it. The file's contents will be read from its beginning. If the file does not exist, \\
the open function fails.
\end{tabular} \\
\hline
\end{tabular}

You cannot change the fact that ifstream files may only be read from, and ofstream files may only be written to. You can, however, vary the way operations are carried out on these files by providing a file access flag as an optional second argument to the open function. The following code shows an example using an ofstream object:
```

ofstream outputFile;
outputFile.open("values.txt", ios::out|ios::app);

```

The ios::app flag specifies that data written to the values.txt file should be appended to its existing contents.

\section*{Checking for a File's Existence Before Opening lt}

Sometimes you want to determine whether a file already exists before opening it for output. You can do this by first attempting to open the file for input. If the file does not exist, the open operation will fail. In that case, you can create the file by opening it for output. The following code gives an example:
```

fstream dataFile;
dataFile.open("values.txt", ios::in);
if (dataFile.fail())
{
// The file does not exist, so create it.
dataFile.open("values.txt", ios::out);
//
// Continue to process the file...
//
}
else // The file already exists.
{
dataFile.close();
cout << "The file values.txt already exists.\n";
}

```

\section*{Opening a File with the File Stream Object Definition Statement}

An alternative to using the open member function is to use the file stream object definition statement to open the file. Here is an example:
```

fstream dataFile("names.txt", ios::in | ios::out);

```

This statement defines an fstream object named dataFile and uses it to open the file names.txt. The file is opened in both input and output modes. This technique eliminates the need to call the open function when your program knows the name and access mode of the file at the time the object is defined. You may also use this technique with ifstream and ofstream objects, as shown in the following examples.
```

ifstream inputFile("info.txt");
ofstream outputFile("addresses.txt");
ofstream dataFile("customers.txt", ios::out|ios::app);

```

You may also test for errors after you have opened a file with this technique. The following code shows an example:
```

ifstream inputFile("SalesData.txt");
if (!inputFile)
cout << "Error opening SalesData.txt.\n";

```

\section*{Checkpoint}
12.1 Which file access flag would you use if you want all output to be written to the end of an existing file?
12.2 How do you use more than one file access flag?
12.3 Assuming diskInfo is an fstream object, write a statement that opens the file names.dat for output.
12.4 Assuming diskInfo is an fstream object, write a statement that opens the file customers.txt for output, where all output will be written to the end of the file.
12.5 Assuming diskInfo is an fstream object, write a statement that opens the file payable.txt for both input and output.
12.6 Write a statement that defines an fstream object named dataFile and opens a file named salesfigures.txt for input. (Note: The file should be opened with the definition statement, not an open function call.)

\subsection*{12.2 File Output Formatting}

CONCEPT: File output may be formatted in the same way that screen output is formatted.

The same output formatting techniques that are used with cout, which are covered in Chapter 3, may also be used with file stream objects. For example, the setprecision and fixed manipulators may be called to establish the number of digits of precision to which floating-point values are rounded Program 12-3 demonstrates this.

\section*{Program 12-3}
```

// This program uses the setprecision and fixed
// manipulators to format file output.
\#include <iostream>
\#include <iomanip>
\#include <fstream>
using namespace std;
int main()
{
fstream dataFile;
doub1e num = 17.816392;
dataFile.open("numfile.txt", ios::out); // Open in output mode

```

\section*{Program 12-3 (continued)}
```

15 dataFile << fixed; // Format for fixed-point notation
dataFile << num << endl; // Write the number
dataFile << setprecision(4); // Format for 4 decimal places
dataFile << num << endl; // Write the number
dataFile << setprecision(3); // Format for 3 decimal places
dataFile << num << endl; // Write the number
dataFile << setprecision(2); // Format for 2 decimal places
dataFile << num << endl; // Write the number
dataFile << setprecision(1); // Format for 1 decimal place
dataFile << num << endl; // Write the number
cout << "Done.\n";
dataFile.close(); // Close the file
return 0;
}

```

\section*{Contents of File numfile.txt}
17.816392
17.8164
17.816
17.82
17.8

Notice the file output is formatted just as cout would format screen output. Program 12-4 shows the setw stream manipulator being used to format file output into columns.

\section*{Program 12-4}
```

// This program writes three rows of numbers to a file.
\#include <iostream>
\#include <fstream>
\#include <iomanip>
using namespace std;
int main()
{
const int ROWS = 3; // Rows to write
const int COLS = 3; // Columns to write
int nums[ROWS][COLS] = { 2897, 5, 837,
34, 7, 1623,
390, 3456, 12 };
fstream outFile("table.txt", ios::out);

```
```

16
1 7
18
19
20
21
22
23
24
25
26
27
28
29 }

```

Contents of File table.txt
\begin{tabular}{rrr}
2897 & 5 & 837 \\
34 & 7 & 1623 \\
390 & 3456 & 12
\end{tabular}

Figure 12-4 shows the way the characters appear in the file.
Figure 12-4 File contents

<EOF>

\subsection*{12.3 Passing File Stream Objects to Functions}

CONCEPT: File stream objects may be passed by reference to functions.
When writing actual programs, you'll want to create modularized code for handling file operations. File stream objects may be passed to functions, but they should always be passed by reference. The openFile function shown below uses an fstream reference object parameter:
```

bool openFileIn(fstream \&file, string name)
{
bool status;
file.open(name, ios::in);

```
```

    if (file.fail())
    status = false;
    else
    status = true;
    return status;
    }

```

The internal state of file stream objects changes with most every operation. They should always be passed to functions by reference to ensure internal consistency. Program 12-5 shows an example of how file stream objects may be passed as arguments to functions.

\section*{Program 12-5}
```

// This program demonstrates how file stream objects may
// be passed by reference to functions.
\#include <iostream>
\#include <fstream>
\#include <string>
using namespace std;
// Function prototypes
bool openFileIn(fstream \&, string);
void showContents(fstream \&);
int main()
{
fstream dataFile;
if (openFileIn(dataFile, "demofile.txt"))
{
cout << "File opened successfully.\n";
cout << "Now reading data from the file.\n\n";
showContents(dataFile);
dataFile.close();
cout << "\nDone.\n";
}
else
cout << "File open error!" << endl;
return 0;
}
//***************************************************************
// Definition of function openFileIn. Accepts a reference
// to an fstream object as an argument. The file is opened
// for input. The function returns true upon success, false *
// upon failure.
/|************************************************************

```
36
```

bool openFileIn(fstream \&file, string name)
{
file.open(name, ios::in);
if (file.fail())
return false;
else
return true;
}
//**************************************************************
// Definition of function showContents. Accepts an fstream
// reference as its argument. Uses a loop to read each name *
// from the file and displays it on the screen.
/|*****************************************************************
void showContents(fstream \&file)
{
string line;
while (file >> line)
{
cout << line << endl;
}
}

```

\section*{Program Output}

File opened successfully.
Now reading data from the file.
Jones
Smith
Willis
Davis
Done.

\subsection*{12.4 More Detailed Error Testing}

CONCEPT: All stream objects have error state bits that indicate the condition of the stream.

All stream objects contain a set of bits that act as flags. These flags indicate the current state of the stream. Table 12-4 lists these bits. These bits can be tested by the member functions listed in Table 12-5. (You've already learned about the fail() function.) One of the functions listed in the table, clear (), can be used to set a status bit.

Table 12-4 Stream Bits
\begin{tabular}{ll}
\hline Bit & Description \\
\hline ios: : eofbit & Set when the end of an input stream is encountered. \\
ios: : failbit & Set when an attempted operation has failed. \\
ios: : hardfait & Set when an unrecoverable error has occurred. \\
ios: : badbit & Set when an invalid operation has been attempted. \\
ios: :goodbit & \begin{tabular}{l} 
Set when all the flags above are not set. Indicates the stream is in good \\
condition.
\end{tabular} \\
\hline
\end{tabular}

\section*{Table 12-5 Functions to Test the State of Stream Bits}

\section*{Function Description}
eof () Returns true (nonzero) if the eofbit flag is set, otherwise returns false.
fail () Returns true (nonzero) if the failbit or hardfail flags are set, otherwise returns false.
bad () Returns true (nonzero) if the badbit flag is set, otherwise returns false.
\(\operatorname{good}() \quad\) Returns true (nonzero) if the goodbit flag is set, otherwise returns false.
clear() When called with no arguments, clears all the flags listed above. Can also be called with a specific flag as an argument.

The function showState, shown here, accepts a file stream reference as its argument. It shows the state of the file by displaying the return values of the eof (), fail(), bad(), and good() member functions.
```

void showState(fstream \&file)
{
cout << "File Status:\n";
cout << " eof bit: " << file.eof() << endl;
cout << " fail bit: " << file.fail() << endl;
cout << " bad bit: " << file.bad() << endl;
cout << " good bit: " << file.good() << endl;
file.clear(); // Clear any bad bits
}

```

Program 12-6 uses the showState function to display testFile's status after various operations. First, the file is created and the integer value 10 is stored in it. The file is then closed and reopened for input. The integer is read from the file, then a second read operation is performed. Because there is only one item in the file, the second read operation will result in an error.

\section*{Program 12-6}
```

// This program demonstrates the return value of the stream
// object error testing member functions.
\#include <iostream>
\#include <fstream>
using namespace std;

```
```

// Function prototype
void showState(fstream \&);
int main()
{
int num = 10;
// Open the file for output.
fstream testFile("stuff.dat", ios::out);
if (testFile.fail())
{
cout << "ERROR: Cannot open the file.\n";
return 0;
}
// Write a value to the file
cout << "Writing the value " << num << " to the file.\n";
testFile << num;
// Show the bit states.
showState(testFile);
// Close the file.
testFile.close();
// Reopen the file for input.
testFile.open("stuff.dat", ios::in);
if (testFile.fail())
{
cout << "ERROR: Cannot open the file.\n";
return 0;
}
// Read the only value from the file.
cout << "Reading from the file.\n";
testFile >> num;
cout << "The value " << num << " was read.\n";
// Show the bit states.
showState(testFile);
// No more data in the file, but force an invalid read operation.
cout << "Forcing a bad read operation.\n";
testFile >> num;
// Show the bit states.
showState(testFile);
// Close the file.
testFile.close();
return 0;
}

```
59

\section*{Program 12-6 (continued)}
```

/|*******************************************************************
// Definition of function showState. This function uses
// an fstream reference as its parameter. The return values of *
// the eof(), fail(), bad(), and good() member functions are *
// displayed. The clear() function is called before the function *
// returns.
/|**********************************************************************
void showState(fstream \&file)
{
cout << "File Status:\n";
cout << " eof bit: " << file.eof() << endl;
cout << " fail bit: " << file.fail() << endl;
cout << " bad bit: " << file.bad() << endl;
cout << " good bit: " << file.good() << endl;
file.clear(); // Clear any bad bits
}

```

\section*{Program Output}
```

Writing the value 10 to the file.

```
File Status:
    eof bit: 0
    fail bit: 0
    bad bit: 0
    good bit: 1
Reading from the file.
The value 10 was read.
File Status:
    eof bit: 1
    fail bit: 0
    bad bit: 0
    good bit: 1
Forcing a bad read operation.
File Status:
    eof bit: 1
    fail bit: 1
    bad bit: 0
    good bit: 0

\subsection*{12.5 Member Functions for Reading and Writing Files}

CONCEPT: File stream objects have member functions for more specialized file reading and writing.

If whitespace characters are part of the data in a file, a problem arises when the file is read by the >> operator. Because the operator considers whitespace characters as delimiters,
it does not read them. For example, consider the file murphy.txt, which contains the following data:

> Jayne Murphy
> 47 Jones Circle
> Almond, NC 28702

Figure 12-5 shows the way the data is recorded in the file.

Figure 12-5 File contents
\begin{tabular}{|l|l|l|l|l|l|l|l|l|l|l|l|l|l|l|}
\hline J & a & y & n & e & & M & u & r & p & n & y & nn & 4 & 7 \\
\hline
\end{tabular}
\begin{tabular}{|c|c|c|c|c|c|c|c|c|c|c|c|c|c|c|}
\hline & J & \(\circ\) & n & e & s & & C & i & r & c & I & e & \(\ln\) & A \\
\hline
\end{tabular}
\begin{tabular}{|c|c|c|c|c|c|c|c|c|c|c|c|c|c|c|}
\hline I & m & o & n & d &, & & N & C & & & 2 & 8 & 7 & 0 \\
\hline
\end{tabular}
\begin{tabular}{|l|l|l|}
\hline 2 & ln & <EOF> \\
\hline
\end{tabular}

The problem that arises from the use of the >> operator is evident in the output of Program 12-7.

\section*{Program 12-7}
// This program demonstrates how the >> operator should not
// be used to read data that contain whitespace characters
// from a file.
\#include <iostream>
\#include <fstream>
\#include <string>
using namespace std;
int main()
\{
```

        string input; // To hold file input
        fstream nameFile; // File stream object
        // Open the file in input mode.
        nameFile.open("murphy.txt", ios::in);
        // If the file was successfully opened, continue.
        if (nameFile)
        {
            // Read the file contents.
            while (nameFile >> input)
            {
                cout << input;
            }
    ```
```

Program 12-7 (continued)
26 // Close the file.
27 nameFile.close();
28 }
29 else
30 {
31 {
32 }
33 return 0;
34 }

```

\section*{Program Output}

\section*{The get 1 ine Function}

The problem with Program 12-7 can be solved by using the getline function. The function reads a "line" of data, including whitespace characters. Here is an example of the function call:
```

getline(dataFile, str,'\n');

```

The three arguments in this statement are explained as follows:
dataFile This is the name of the file stream object. It specifies the stream object from which the data is to be read.
str \(\quad\) This is the name of a string object. The data read from the file will be stored here.
' \(\backslash n\) ' This is a delimiter character of your choice. If this delimiter is encountered, it will cause the function to stop reading. (This argument is optional. If it's left out, ' \(\backslash n\) ' is the default.)
The statement is an instruction to read a line of characters from the file. The function will read until it encounters a \(\backslash \mathrm{n}\). The line of characters will be stored in the str object.

Program 12-8 is a modification of Program 12-7. It uses the getline function to read whole lines of data from the file.

\section*{Program 12-8}
```

// This program uses the getline function to read a line of
// data from the file.
\#include <iostream>
\#include <fstream>
\#include <string>
using namespace std;
int main()

```
```

{
string input; // To hold file input
fstream nameFile; // File stream object
// Open the file in input mode.
nameFile.open("murphy.txt", ios::in);
// If the file was successfully opened, continue.
if (nameFile)
{
// Read an item from the file.
getline(nameFile, input);
// While the last read operation
// was successful, continue.
while (nameFile)
{
// Display the last item read.
cout << input << endl;
// Read the next item.
getline(nameFile, input);
}
// Close the file.
nameFile.close();
}
else
{
cout << "ERROR: Cannot open file.\n";
}
return 0;
}

```

\section*{Program Output}

Jayne Murphy
47 Jones Circle
Almond, NC 28702
Because the third argument of the getline function was left out in Program 12-8, its default value is n . Sometimes you might want to specify another delimiter. For example, consider a file that contains multiple names and addresses, and that is internally formatted in the following manner:

\section*{Contents of names2.txt}

Jayne Murphy\$47 Jones Circle\$Almond, NC 28702 \n\$Bobbie Smith\$ 217 Halifax Drive\$Canton, NC 28716\n\$Bi11 Hammet\$PO Box 121\$ Springfield, NC \(28357 \backslash n \$\)

Think of this file as consisting of three records. A record is a complete set of data about a single item. Also, the records in the file above are made of three fields. The first field is the person's name. The second field is the person's street address or PO box number. The third field contains the person's city, state, and ZIP code. Notice each field ends with a \(\$\) character, and each record ends with a \(\ln\) character. Program 12-9 demonstrates how a getline function can be used to detect the \(\$\) characters.

\section*{Program 12-9}
```

// This file demonstrates the getline function with
// a specified delimiter.
\#include <iostream>
\#include <fstream>
\#include <string>
using namespace std;
int main()
{
string input; // To hold file input
// Open the file for input.
fstream dataFile("names2.txt", ios::in);
// If the file was successfully opened, continue.
if (dataFile)
{
// Read an item using \$ as a delimiter.
getline(dataFile, input, '\$');
// While the last read operation
/l was successful, continue.
while (dataFile)
{
// Display the last item read.
cout << input << endl;
// Read an item using \$ as a delimiter.
getline(dataFile, input, '\$');
}
// Close the file.
dataFile.close();
}
else
{
cout << "ERROR: Cannot open file.\n";
}
return 0;
}

```

\section*{Program Output}

Bil1 Hammet
PO Box 121
Springfield, NC 28357

Notice the In characters, which mark the end of each record, are also part of the output. They cause an extra blank line to be printed on the screen, separating the records.

NOTE: When using a printable character, such as \(\$\), to delimit data in a file, be sure to select a character that will not actually appear in the data itself. Since it's doubtful that anyone's name or address contains a \$ character, it's an acceptable delimiter. If the file contained dollar amounts, however, another delimiter would have been chosen.

\section*{The get Member Function}

The file stream object's get member function is also useful. It reads a single character from the file. Here is an example of its usage:
```

inFile.get(ch);

```

In this example, ch is a char variable. A character will be read from the file and stored in ch. Program 12-10 shows the function used in a complete program. The user is asked for the name of a file. The file is opened and the get function is used in a loop to read the file's contents, one character at a time.

\section*{Program 12-10}
```

// This program asks the user for a file name. The file is
// opened and its contents are displayed on the screen.
\#include <iostream>
\#include <fstream>
\#include <string>
using namespace std;
int main()
{
string fileName; // To hold the file name
char ch; // To hold a character
fstream file; // File stream object
// Get the file name
cout << "Enter a file name: ";
cin >> fileName;
// Open the file.
file.open(filename, ios::in);
// If the file was successfully opened, continue.
if (file)
{
// Get a character from the file.
file.get(ch);
// While the last read operation was
// successful, continue.
while (file)
{

```
```

Program 12-10 (continued)

32
33
34
35
36
37
38
39
4 0
4 1
4 2
4 3
44 }

```

Program 12-10 will display the contents of any file. The get function even reads whitespaces, so all the characters will be shown exactly as they appear in the file.

\section*{The put Member Function}

The put member function writes a single character to the file. Here is an example of its usage:
```

outFile.put(ch);

```

In this statement, the variable ch is assumed to be a char variable. Its contents will be written to the file associated with the file stream object outFile. Program 12-11 demonstrates the put function.

\section*{Program 12-11}
```

// This program demonstrates the put member function.
\#include <iostream>
\#include <fstream>
using namespace std;
int main()
{
char ch; // To hold a character
// Open the file for output.
fstream dataFile("sentence.txt", ios::out);
cout << "Type a sentence and be sure to end it with a ";
cout << "period.\n";
// Get a sentence from the user one character at a time
// and write each character to the file.
cin.get(ch);
while (ch != '.')
{
dataFile.put(ch);
cin.get(ch);
}

```
```

    dataFile.put(ch); // Write the period.
    26 // Close the file.
27 dataFile.close();
28 return 0;

```
25
29 \}

\section*{Program Output with Example Input Shown in Bold}

\section*{Checkpoint}
12.7 Assume the file input.txt contains the following characters:
\begin{tabular}{|c|c|c|c|c|c|c|c|c|c|c|c|c|c|c|}
\hline\(R\) & \(u\) & n & & S & p & o & t & & r & u & n & \(\ln\) & S & e \\
\hline
\end{tabular}
\begin{tabular}{|c|c|c|c|c|c|c|c|c|c|c|c|}
\hline e & & S & p & o & t & & r & u & n & ln & \(<E O F\rangle\) \\
\hline
\end{tabular}

What will the following program display on the screen?
```

\#include <iostream>
\#include <fstream>
\#include <string>
using namespace std;
int main()
{
fstream inFile("input.txt", ios::in);
string item;
inFile >> item;
while (inFile)
{
cout << item << endl;
inFile >> item;
}
inFile.close();
return 0;
}

```
12.8 Describe the difference between reading a file with the >> operator and the getline function.
12.9 What will be stored in the file out.txt after the following program runs?
```

\#include <iostream>
\#include <fstream>
\#include <iomanip>
using namespace std;

```
```

int main()
{
const int SIZE = 5;
ofstream outFile("out.txt");
double nums[SIZE] = {100.279, 1.719, 8.602, 7.777, 5.099};
outFile << fixed << setprecision(2);
for (int count = 0; count < 5; count++)
{
outFile << setw(8) << nums[count];
}
outFile.close();
return 0;
}

```

\subsection*{12.6 Focus on Software Engineering: Working with Multiple Files}

CONCEPT: It's possible to have more than one file open at once in a program.

VideoNote
Working with Multiple Files

Quite often you will need to have multiple files open at once. In many real-world applications, data about a single item are categorized and written to several different files. For example, a payroll system might keep the following files:
emp.dat A file that contains the following data about each employee: name, job title, address, telephone number, employee number, and the date hired.
pay.dat A file that contains the following data about each employee: employee number, hourly pay rate, overtime rate, and number of hours worked in the current pay cycle.
withhold.dat A file that contains the following data about each employee: employee number, dependents, and extra withholdings.

When the system is writing paychecks, you can see that it will need to open each of the files listed above and read data from them. (Notice each file contains the employee number. This is how the program can locate a specific employee's data.)
In C++, you open multiple files by defining multiple file stream objects. For example, if you need to read from three files, you can define three file stream objects, such as:
```

ifstream file1, file2, file3;

```

Sometimes you will need to open one file for input and another file for output. For example, Program 12-12 asks the user for a file name. The file is opened and read. Each character is converted to uppercase and written to a second file called out.txt. This type of program can be considered a filter. Filters read the input of one file, changing the data in some fashion, and write it out to a second file. The second file is a modified version of the first file.

\section*{Program 12-12}
// This program demonstrates reading from one file and writing // to a second file.
\#include <iostream>
\#include <fstream>
\#include <string>
\#include <cctype> // Needed for the toupper function.
using namespace std;
int main()
\{
    string fileName; // To hold the file name
    char ch; // To hold a character
    ifstream inFile; // Input file
    // Open a file for output.
    ofstream outFile("out.txt");
    // Get the input file name.
    cout << "Enter a file name: ";
    cin >> fileName;
    // Open the file for input.
    inFile.open(filename);
    // If the input file opened successfully, continue.
    if (inFile)
    \{
        // Read a char from file 1.
        inFile.get(ch);
            // While the last read operation was
            // successful, continue.
            while (inFile)
            \{
                // Write uppercase char to file 2.
                outFile.put (toupper(ch)) ;
                // Read another char from file 1.
                inFile.get(ch);
            \}
            // Close the two files.
            inFile.close();
            outFile.close();
            cout << "File conversion done. In";
    \}
    else
            cout << "Cannot open " << fileName << endl;
        return 0;
\}
```

Program 12-12 (continued)

\subsection*{12.7 Binary Files}

CONCEPT: Binary files contain data that is not necessarily stored as ASCII text.
All the files you've been working with so far have been text files. That means the data stored in the files has been formatted as ASCII text. Even a number, when stored in a file with the << operator, is converted to text. For example, consider the following program segment:
```

ofstream file("num.dat");
short x = 1297;
file << x;

```

The last statement writes the contents of x to the file. When the number is written, however, it is stored as the characters '1', '2', '9', and '7'. This is illustrated in Figure 12-6.

Figure 12-6 File contents
\begin{tabular}{|c|c|c|c|c|}
\hline '1' & '2' & '9' & '7' & <EOF> \\
\hline
\end{tabular}

1297 expressed in ASCII
\begin{tabular}{|l|l|l|l|l|}
\hline 49 & 50 & 57 & 55 & <EOF> \\
\hline
\end{tabular}

The number 1297 isn't stored in memory (in the variable x ) in the fashion depicted in the figure above, however. It is formatted as a binary number, occupying 2 bytes on a typical system. Figure 12-7 shows how the number is represented in memory, using binary or hexadecimal.

Figure 12-7 The value 1297 stored as a short int
1297 as a short integer, in binary
0000010100010001

1297 as a short integer, in hexadecimal
\begin{tabular}{|l|l|}
\hline 05 & 11 \\
\hline
\end{tabular}

The representation of the number shown in Figure 12-7 is the way the "raw" data is stored in memory. Data can be stored in a file in its pure, binary format. The first step is to open the file in binary mode. This is accomplished by using the ios: :binary flag. Here is an example:
```

file.open("stuff.dat", ios::out | ios::binary);

```

Notice the ios: :out and ios::binary flags are joined in the statement with the |operator. This causes the file to be opened in both output and binary modes.

NOTE: By default, files are opened in text mode.

\section*{The write and read Member Functions}

The file stream object's write member function is used to write binary data to a file. The general format of the write member function is
```

fileObject.write(address, size);

```

Let's look at the parts of this function call format:
- fileObject is the name of a file stream object.
- address is the starting address of the section of memory that is to be written to the file. This argument is expected to be the address of a char (or a pointer to a char).
- size is the number of bytes of memory to write. This argument must be an integer value.

For example, the following code uses a file stream object named file to write a character to a binary file:
```

char letter = 'A';
file.write(\&letter, sizeof(letter));

```

The first argument passed to the write function is the address of the letter variable. This tells the write function where the data that is to be written to the file is located. The second argument is the size of the letter variable, which is returned from the sizeof operator. This tells the write function the number of bytes of data to write to the file. Because the sizes of data types can vary among systems, it is best to use the sizeof operator to determine the number of bytes to write. After this function call executes, the contents of the letter variable will be written to the binary file associated with the file object.
The following code shows another example. This code writes an entire char array to a binary file.
```

char data[] = {'A', 'B', 'C', 'D'};
file.write(data, sizeof(data));

```

In this code, the first argument is the name of the data array. By passing the name of the array, we are passing a pointer to the beginning of the array. Because data is an array of char values, the name of the array is a pointer to a char. The second argument passes the name of the array to the sizeof operator. When the name of an array is passed to the sizeof operator, the operator returns the number of bytes allocated to the array. After this function call executes, the contents of the data array will be written to the binary file associated with the file object.

The read member function is used to read binary data from a file into memory. The general format of the read member function is
```

fileObject.read(address, size);

```

Here are the parts of this function call format:
- fileObject is the name of a file stream object.
- address is the starting address of the section of memory where the data being read from the file is to be stored. This is expected to be the address of a char (or a pointer to a char).
- size is the number of bytes of memory to read from the file. This argument must be an integer value.

For example, suppose we want to read a single character from a binary file and store that character in the letter variable. The following code uses a file stream object named file to do just that:
```

char letter;
file.read(\&letter, sizeof(letter));

```

The first argument passed to the read function is the address of the letter variable. This tells the read function where to store the value that is read from the file. The second argument is the size of the letter variable. This tells the read function the number of bytes to read from the file. After this function executes, the 1etter variable will contain a character that was read from the file.

The following code shows another example. This code reads enough data from a binary file to fill an entire char array.
```

char data[4];
file.read(data, sizeof(data));

```

In this code, the first argument is the address of the data array. The second argument is the number of bytes allocated to the array. On a system that uses 1-byte characters, this function will read 4 bytes from the file and store them in the data array.
Program 12-13 demonstrates writing a char array to a file then reading the data from the file back into memory.

\section*{Program 12-13}
```

// This program uses the write and read functions.

```
// This program uses the write and read functions.
#include <iostream>
#include <iostream>
#include <fstream>
#include <fstream>
using namespace std;
using namespace std;
int main()
int main()
{
{
    const int SIZE = 4;
    const int SIZE = 4;
    char data[SIZE] = {'A', 'B', 'C', 'D'};
    char data[SIZE] = {'A', 'B', 'C', 'D'};
    fstream file;
```

    fstream file;
    ```
```

    // Open the file for output in binary mode.
    file.open("test.dat", ios::out | ios::binary);
    // Write the contents of the array to the file.
    cout << "Writing the characters to the file.ln";
    file.write(data, sizeof(data));
    // Close the file.
    file.close();
    // Open the file for input in binary mode.
    file.open("test.dat", ios::in | ios::binary);
    // Read the contents of the file into the array.
    cout << "Now reading the data back into memory.\n";
    file.read(data, sizeof(data));
    // Display the contents of the array.
    for (int count = 0; count < SIZE; count++)
        cout << data[count] << " ";
    cout << endl;
    // Close the file.
    file.close();
    return 0;
    }

```

\section*{Program Output}

Writing the characters to the file.
Now reading the data back into memory.
A B C D

\section*{Writing Data other than char to Binary Files}

Because the write and read member functions expect their first argument to be a pointer to a char, you must use a type cast when writing and reading items that are of other data types. To convert a pointer from one type to another, you should use the reinterpret_ cast type cast. The general format of the type cast is
```

reinterpret_cast<dataType>(value)

```
where dataType is the data type that you are converting to, and value is the value that you are converting. For example, the following code uses the type cast to store the address of an int in a char pointer variable:
```

int x = 65;
char *ptr = nullptr;
ptr = reinterpret_cast<char *>(\&x);

```

The following code shows how to use the type cast to pass the address of an integer as the first argument to the write member function:
```

int x = 27;
file.write(reinterpret_cast<char *>(\&x), sizeof(x));

```

After the function executes, the contents of the variable x will be written to the binary file associated with the file object. The following code shows an int array being written to a binary file:
```

const int SIZE = 10;
int numbers[SIZE] = {1, 2, 3, 4, 5, 6, 7, 8, 9, 10};
file.write(reinterpret_cast<char *>(numbers), sizeof(numbers));

```

After this function call executes, the contents of the numbers array will be written to the binary file. The following code shows values being read from the file and stored into the numbers array:
```

const int SIZE = 10;
int numbers[SIZE];
file.read(reinterpret_cast<char *>(numbers), sizeof(numbers));

```

Program 12-14 demonstrates writing an int array to a file then reading the data from the file back into memory.

\section*{Program 12-14}
```

// This program uses the write and read functions.
\#include <iostream>
\#include <fstream>
using namespace std;
int main()
{
const int SIZE = 10;
fstream file;
int numbers[SIZE] = {1, 2, 3, 4, 5, 6, 7, 8, 9, 10};
// Open the file for output in binary mode.
file.open("numbers.dat", ios::out | ios::binary);
// Write the contents of the array to the file.
cout << "Writing the data to the file.\n";
file.write(reinterpret_cast<char *>(numbers), sizeof(numbers));
// Close the file.
file.close();
// Open the file for input in binary mode.
file.open("numbers.dat", ios::in | ios::binary);
// Read the contents of the file into the array.
cout << "Now reading the data back into memory.\n";
file.read(reinterpret_cast<char *>(numbers), sizeof(numbers));
// Display the contents of the array.
for (int count = 0; count < SIZE; count++)
cout << numbers[count] << " ";
cout << endl;
// Close the file.
file.close();
return 0;
}

```

\section*{Program Output}

Writing the data to the file.
Now reading the data back into memory.
12345678910

\subsection*{12.8 Creating Records with Structures}

CONCEPT: Structures may be used to store fixed-length records to a file.
Earlier in this chapter, the concept of fields and records was introduced. A field is an individual piece of data pertaining to a single item. A record is made up of fields and is a complete set of data about a single item. For example, a set of fields might be a person's name, age, address, and phone number. Together, all those fields that pertain to one person make up a record.

In C++, structures provide a convenient way to organize data into fields and records. For example, the following code could be used to create a record containing data about a person:
```

const int NAME_SIZE = 51, ADDR_SIZE = 51, PHONE_SIZE = 14;
struct Info
{
char name[NAME_SIZE];
int age;
char address1[ADDR_SIZE];
char address2[ADDR_SIZE];
char phone[PHONE_SIZE];
};

```

Besides providing an organizational structure for data, structures also package data into a single unit. For example, assume the structure variable person is defined as
```

Info person;

```

Once the members (or fields) of person are filled with data, the entire variable may be written to a file using the write function:
```

file.write(reinterpret_cast<char *>(\&person), sizeof(person));

```

The first argument is the address of the person variable. The reinterpret_cast operator is used to convert the address to a char pointer. The second argument is the sizeof operator with person as its argument. This returns the number of bytes used by the person structure. Program 12-15 demonstrates this technique.

NOTE: Because structures can contain a mixture of data types, you should always use the ios::binary mode when opening a file to store them.

\section*{Program 12-15}
// This program uses a structure variable to store a record to a file.
\#include <iostream>
\#include <fstream>
using namespace std;
// Array sizes
const int NAME_SIZE = 51, ADDR_SIZE = 51, PHONE_SIZE = 14;
// Declare a structure for the record.
struct Info
\{
char name[NAME_SIZE];
int age;
char address1[ADDR_SIZE];
char address2[ADDR_SIZE];
char phone[PHONE_SIZE];
\};
int main()
\{
Info person; // To hold info about a person
char again; \(/ /\) To hold \(Y\) or \(N\)
// Open a file for binary output.
fstream people("people.dat", ios::out | ios::binary);
do
\{
// Get data about a person.
cout << "Enter the following data about a "
<< "person:\n";
cout << "Name: ";
cin.get1ine(person.name, NAME_SIZE);
cout << "Age: ";
cin >> person.age;
cin.ignore(); // Skip over the remaining newline.
cout << "Address line 1: ";
cin.get1ine(person.address1, ADDR_SIZE);
cout << "Address line 2: ";
cin.get1ine(person.address2, ADDR_SIZE);
cout << "Phone: ";
cin.get1ine(person.phone, PHONE_SIZE);
// Write the contents of the person structure to the file.
people.write(reinterpret_cast<char *>(\&person), sizeof(person));
// Determine whether the user wants to write another record.
cout << "Do you want to enter another record? ";
cin >> again;
cin.ignore(); // Skip over the remaining newline.
\} while (again == 'Y' || again == 'y');
```

54 // Close the file.
55 people.close();
56 return 0;
57 }

```

\section*{Program Output with Example Input Shown in Bold}
```

Enter the following data about a person:

```
Name: Charlie Baxter Enter
Age: 42 Enter
Address line 1: 67 Kennedy Blvd. Enter
Address line 2: Perth, SC 38754 Enter
Phone: (803)555-1234 Enter
Do you want to enter another record? \(\mathbf{Y}\) Enter
Enter the following data about a person:
Name: Merideth Murney Enter
Age: 22 Enter
Address line 1: 487 Lindsay Lane Enter
Address line 2: Hazelwood, NC 28737 Enter
Phone: (828)555-9999 Enter
Do you want to enter another record? \(\mathbf{N}\) Enter

Program 12-15 allows you to build a file by filling the members of the person variable, then writing the variable to the file. Program 12-16 opens the file and reads each record into the person variable, then displays the data on the screen.

\section*{Program 12-16}
```

// This program uses a structure variable to read a record from a file.
\#include <iostream>
\#include <fstream>
using namespace std;
const int NAME_SIZE = 51, ADDR_SIZE = 51, PHONE_SIZE = 14;
// Declare a structure for the record.
struct Info
{
char name[NAME_SIZE];
int age;
char address1[ADDR_SIZE];

## Program Output (Using the same file created by Program 12-15 as input)

Here are the people in the file:
Name: Charlie Baxter
Age: 42
Address line 1: 67 Kennedy B1vd.
Address 1ine 2: Perth, SC 38754
Phone: (803)555-1234

```
Press the Enter key to see the next record.
Name: Merideth Murney
Age: 22
Address line 1: 487 Lindsay Lane
Address line 2: Hazelwood, NC 28737
Phone: (828)555-9999
Press the Enter key to see the next record.
That's all the data in the file!
```

NOTE: Structures containing pointers cannot be correctly stored to disk using the techniques of this section. This is because if the structure is read into memory on a subsequent run of the program, it cannot be guaranteed that all program variables will be at the same memory locations. Because string class objects contain implicit pointers, they cannot be a part of a structure that has to be stored.

### 12.9 Random-Access Filles

CONCEPT: Random access means nonsequentially accessing data in a file.
All of the programs created so far in this chapter have performed sequential file access. When a file is opened, the position where reading and/or writing will occur is at the file's beginning (unless the ios: :app mode is used, which causes data to be written to the end of the file). If the file is opened for output, bytes are written to it one after the other. If the file is opened for input, data is read beginning at the first byte. As the reading or writing continues, the file stream object's read/write position advances sequentially through the file's contents.

The problem with sequential file access is that in order to read a specific byte from the file, all the bytes that precede it must be read first. For instance, if a program needs data stored at the hundredth byte of a file, it will have to read the first 99 bytes to reach it. If you've ever listened to a cassette tape player, you understand sequential access. To listen to a song at the end of the tape, you have to listen to all the songs that come before it, or fast-forward over them. There is no way to immediately jump to that particular song.
Although sequential file access is useful in many circumstances, it can slow a program down tremendously. If the file is very large, locating data buried deep inside it can take a long time. Alternatively, C++ allows a program to perform random file access. In random file access, a program may immediately jump to any byte in the file without first reading the preceding bytes. The difference between sequential and random file access is like the difference between a cassette tape and a compact disc. When listening to a CD, there is no need to listen to or fast forward over unwanted songs. You simply jump to the track that you want to listen to. This is illustrated in Figure 12-8.

## The seekp and seekg Member Functions

File stream objects have two member functions that are used to move the read/write position to any byte in the file. They are seekp and seekg. The seekp function is used with

Figure 12-8 Sequential versus random access
Sequential access

Random access

files opened for output, and seekg is used with files opened for input. (It makes sense if you remember that " p " stands for "put" and " g " stands for "get." seekp is used with files into which you put data, and seekg is used with files from which you get data out.)

Here is an example of seekp's usage:
file.seekp(20L, ios::beg);
The first argument is a long integer representing an offset into the file. This is the number of the byte to which you wish to move. In this example, 20L is used. (Remember, the L suffix forces the compiler to treat the number as a long integer.) This statement moves the file's write position to byte number 20. (All numbering starts at 0 , so byte number 20 is actually the twenty-first byte.)

The second argument is called the mode, and it designates where to calculate the offset from. The flag ios::beg means the offset is calculated from the beginning of the file. Alternatively, the offset can be calculated from the end of the file or the current position in the file. Table 12-6 lists the flags for all three of the random-access modes.

Table 12-6 Offset Modes

| Mode Flag | Description |
| :--- | :--- |
| ios::beg | The offset is calculated from the beginning of the file. |
| ios: :end | The offset is calculated from the end of the file. |
| ios: :cur | The offset is calculated from the current position. |

Table 12-7 shows examples of seekp and seekg using the various mode flags.
Notice some of the examples in Table 12-7 use a negative offset. Negative offsets result in the read or write position being moved backward in the file, while positive offsets result in a forward movement.

Assume the file letters.txt contains the following data:
abcdefghijk1mnopqrstuvwxyz
Program 12-17 uses the seekg function to jump around to different locations in the file, retrieving a character after each stop.

Table 12-7 Mode Examples

| Statement | How It Affects the Read/Write Position |
| :--- | :--- |
| file.seekp(32L, ios::beg); | Sets the write position to the 3 3rd byte (byte 32) from the <br> beginning of the file. |
| file.seekp(-10L, ios::end); | Sets the write position to the 10th byte from the end of the file. |
| file.seekp(120L, ios::cur); | Sets the write position to the 121st byte (byte 120) from the |
| current position. |  |

## Program 12-17

```
// This program demonstrates the seekg function.
#include <iostream>
#include <fstream>
using namespace std;
int main()
{
    char ch; // To hold a character
    // Open the file for input.
    fstream file("letters.txt", ios::in);
    // Move to byte 5 from the beginning of the file
    // (the 6th byte) and read the character there.
    file.seekg(5L, ios::beg);
    file.get(ch);
    cout << "Byte 5 from beginning: " << ch << endl;
    // Move to the 10th byte from the end of the file
    // and read the character there.
    file.seekg(-10L, ios::end);
    file.get(ch);
    cout << "10th byte from end: " << ch << endl;
    // Move to byte 3 from the current position
    // (the 4th byte) and read the character there.
    file.seekg(3L, ios::cur);
    file.get(ch);
    cout << "Byte 3 from current: " << ch << endl;
    file.close();
    return 0;
}
```

## Program 12-17 (continued)

## Program Screen Output

```
Byte 5 from beginning: f
10th byte from end: q
Byte 3 from current: u
```

Program 12-18 shows a more robust example of the seekg function. It opens the people. dat file created by Program 12-15. The file contains two records. Program 12-18 displays record 1 (the second record) first, then displays record 0 .
The program has two important functions other than main. The first, byteNum, takes a record number as its argument and returns that record's starting byte. It calculates the record's starting byte by multiplying the record number by the size of the Info structure. This returns the offset of that record from the beginning of the file. The second function, showRec, accepts an Info structure as its argument and displays its contents on the screen.

## Program 12-18

```
// This program randomly reads a record of data from a file.
#include <iostream>
#include <fstream>
using namespace std;
const int NAME_SIZE = 51, ADDR_SIZE = 51, PHONE_SIZE = 14;
// Declare a structure for the record.
struct Info
{
    char name[NAME_SIZE];
    int age;
    char address1[ADDR_SIZE];
    char address2[ADDR_SIZE];
    char phone[PHONE_SIZE];
};
// Function Prototypes
long byteNum(int);
void showRec(Info);
int main()
{
    Info person; // To hold info about a person
    fstream people; // File stream object
    // Open the file for input in binary mode.
    people.open("people.dat", ios::in | ios::binary);
```

```
    // Test for errors.
    if (!people)
    {
        cout << "Error opening file. Program aborting.\n";
        return 0;
    }
    // Read and display record 1 (the second record).
    cout << "Here is record 1:\n";
    people.seekg(byteNum(1), ios::beg);
    people.read(reinterpret_cast<char *>(&person), sizeof(person));
    showRec(person);
    // Read and display record 0 (the first record).
    cout << "\nHere is record 0:\n";
    people.seekg(byteNum(0), ios::beg);
    people.read(reinterpret_cast<char *>(&person), sizeof(person));
    showRec(person);
    // Close the file.
    people.close();
    return 0;
}
//************************************************************
// Definition of function byteNum. Accepts an integer as
// its argument. Returns the byte number in the file of the *
// record whose number is passed as the argument.
//**
long byteNum(int recNum)
{
        return sizeof(Info) * recNum;
}
/|************************************************************
// Definition of function showRec. Accepts an Info structure *
// as its argument, and displays the structure's contents.
//*************************************************************
void showRec(Info record)
{
    cout << "Name: ";
    cout << record.name << endl;
    cout << "Age: ";
    cout << record.age << endl;
    cout << "Address line 1: ";
    cout << record.address1 << endl;
    cout << "Address 1ine 2: ";
    cout << record.address2 << endl;
```

```
Program 12-18 (continued)
80 cout << "Phone: ";
81 cout << record.phone << endl;
82 }
Program Output (Using the same file created by Program 12-15 as input)
Here is record 1:
Name: Merideth Murney
Age: 22
Address line 1: 487 Lindsay Lane
Address line 2: Hazelwood, NC 28737
Phone: (828)555-9999
Here is record 0:
Name: Charlie Baxter
Age: 42
Address line 1: 67 Kennedy Blvd.
Address 1ine 2: Perth, SC 38754
Phone: (803)555-1234
```

WARNING! If a program has read to the end of a file, you must call the file stream object's clear member function before calling seekg or seekp. This clears the file stream object's eof flag. Otherwise, the seekg or seekp function will not work.

## The te11p and te11g Member Functions

File stream objects have two more member functions that may be used for random file access: tellp and tellg. Their purpose is to return, as a long integer, the current byte number of a file's read and write position. As you can guess, tel1p returns the write position and tellg returns the read position. Assuming pos is a long integer, here is an example of the functions' usage:

```
pos = outFile.tellp();
pos = inFile.tellg();
```

One application of these functions is to determine the number of bytes that a file contains. The following example demonstrates how to do this using the tellg function:

```
file.seekg(OL, ios::end);
numBytes = file.tellg();
cout << "The file has " << numBytes << " bytes.\n";
```

First, the seekg member function is used to move the read position to the last byte in the file. Then, the tellg function is used to get the current byte number of the read position.

Program 12-19 demonstrates the tellg function. It opens the letters.txt file, which was also used in Program 12-17. The file contains the following characters:
abcdefghijk1mnopqrstuvwxyz

## Program 12-19

// This program demonstrates the tellg function. \#include <iostream>
\#include <fstream>
using namespace std;
int main()
\{
long offset; // To hold an offset amount
long numBytes; // To hold the file size
char ch; // To hold a character
char again; // To hold Y or $N$
// Open the file for input.
fstream file("letters.txt", ios::in);
// Determine the number of bytes in the file.
file.seekg(0L, ios::end);
numBytes = file.tellg();
cout << "The file has " << numBytes << " bytes. In";
// Go back to the beginning of the file.
file.seekg(OL, ios: beg);
// Let the user move around within the file.
do
\{
// Display the current read position.
cout << "Currently at position " << file.tellg() << endi;
// Get a byte number from the user.
cout << "Enter an offset from the beginning of the file: ";
cin >> offset;
// Move the read position to that byte, read the
// character there, and display it.
if (offset >= numBytes) // Past the end of the file?
cout << "Cannot read past the end of the file.ln";
else
\{
file.seekg(offset, ios::beg);
file.get(ch);
cout << "Character read: " << ch << endl;
\}
// Does the user want to try this again?
cout << "Do it again? ";
cin >> again;
\} while (again == 'Y' || again == 'y');
// Close the file.
file.close();
return 0;
\}

## Program 12-19 <br> (continued)

## Program Output with Example Input Shown in Bold

```
The file has 26 bytes.
Currently at position 0
Enter an offset from the beginning of the file: 5 Enter
Character read: f
Do it again? y Enter
Currently at position 6
Enter an offset from the beginning of the file: 0 Enter
Character read: a
Do it again? y Enter
Currently at position 1
Enter an offset from the beginning of the file: 26 Enter
Cannot read past the end of the file.
Do it again? n Enter
```

## Rewinding a Sequential-Access File with seekg

Sometimes when processing a sequential file, it is necessary for a program to read the contents of the file more than one time. For example, suppose a program searches a file for an item specified by the user. The program must open the file, read its contents, and determine if the specified item is in the file. If the user needs to search the file again for another item, the program must read the file's contents again.

One simple approach for reading a file's contents more than once is to close and reopen the file, as shown in the following code example:

```
dataFile.open("file.txt", ios::in); // Open the file.
/ /
// Read and process the file's contents.
/ /
dataFile.close(); // Close the file.
dataFile.open("file.txt", ios::in); /l Open the file again.
//
// Read and process the file's contents again.
/ /
dataFile.close(); // Close the file.
```

Each time the file is reopened, its read position is located at the beginning of the file. The read position is the byte in the file that will be read with the next read operation.

Another approach is to "rewind" the file. This means moving the read position to the beginning of the file without closing and reopening it. This is accomplished with the file stream object's seekg member function to move the read position back to the beginning of the file. The following example code demonstrates this.

```
dataFile.open("file.txt", ios::in); // Open the file.
//
// Read and process the file's contents.
//
```

```
dataFile.clear(); // Clear the eof flag.
dataFile.seekg(0L, ios::beg); // Rewind the read position.
/ /
// Read and process the file's contents again.
/ /
dataFile.close(); // Close the file.
```

Notice prior to calling the seekg member function, the clear member function is called. As previously mentioned, this clears the file object's eof flag and is necessary only if the program has read to the end of the file. This approach eliminates the need to close and reopen the file each time the file's contents are processed.

### 12.10 Opening a File for Both Input and Output

CONCEPT: You may perform input and output on an fstream file without closing it and reopening it.

Sometimes you'll need to perform both input and output on a file without closing and reopening it. For example, consider a program that allows you to search for a record in a file then make changes to it. A read operation is necessary to copy the data from the file to memory. After the desired changes have been made to the data in memory, a write operation is necessary to replace the old data in the file with the new data in memory.

Such operations are possible with fstream objects. The ios::in and ios: :out file access flags may be joined with the \| operator, as shown in the following statement:

```
fstream file("data.dat", ios::in | ios::out)
```

The same operation may be accomplished with the open member function.

```
file.open("data.dat", ios::in | ios::out);
```

You may also specify the ios: :binary flag if binary data is to be written to the file. Here is an example:

```
file.open("data.dat", ios::in | ios::out | ios::binary);
```

When an fstream file is opened with both the ios::in and ios::out flags, the file's current contents are preserved, and the read/write position is initially placed at the beginning of the file. If the file does not exist, it is created.
Programs 12-20, 12-21, and 12-22 demonstrate many of the techniques we have discussed. Program 12-20 sets up a file with five blank inventory records. Each record is a structure with members for holding a part description, quantity on hand, and price. Program 12-21 displays the contents of the file on the screen. Program 12-22 opens the file in both input and output modes and allows the user to change the contents of a specific record.

## Program 12-20

```
// This program sets up a file of blank inventory records.
#include <iostream>
#include <fstream>
using namespace std;
// Constants
const int DESC_SIZE = 31; // Description size
const int NUM_RECORDS = 5; // Number of records
// Declaration of InventoryItem structure
struct InventoryItem
{
    char desc[DESC_SIZE];
    int qty;
    double price;
};
int main()
{
    // Create an empty InventoryItem structure.
    InventoryItem record = { "", 0, 0.0 };
    // Open the file for binary output.
    fstream inventory("Inventory.dat", ios::out | ios::binary);
    // Write the blank records
    for (int count = 0; count < NUM_RECORDS; count++)
    {
        cout << "Now writing record " << count << endl;
        inventory.write(reinterpret_cast<char *>(&record),
                                    sizeof(record));
    }
    // Close the file.
    inventory.close();
    return 0;
}
```

## Program Output

Now writing record 0
Now writing record 1
Now writing record 2
Now writing record 3
Now writing record 4

Program 12-21 simply displays the contents of the inventory file on the screen. It can be used to verify that Program 12-20 successfully created the blank records, and that Program 12-22 correctly modified the designated record.

## Program 12-21

```
// This program displays the contents of the inventory file.
#include <iostream>
#include <fstream>
using namespace std;
const int DESC_SIZE = 31; // Description size
// Declaration of InventoryItem structure
struct InventoryItem
{
    char desc[DESC_SIZE];
    int qty;
    doubTe price;
};
int main()
{
    InventoryItem record; // To hold an inventory record
    // Open the file for binary input.
    fstream inventory("Inventory.dat", ios::in | ios::binary);
    // Now read and display the records
    inventory.read(reinterpret_cast<char *>(&record),
                                    sizeof(record));
    while (!inventory.eof())
    {
        cout << "Description: ";
        cout << record.desc << endl;
        cout << "Quantity: ";
        cout << record.qty << endl;
        cout << "Price: ";
        cout << record.price << endl << endl;
        inventory.read(reinterpret_cast<char *>(&record),
            sizeof(record));
        }
    // Close the file.
    inventory.close();
    return 0;
}
```

Here is the screen output of Program 12-21 if it is run immediately after Program 12-20 sets up the file of blank records.

## Program 12-21

## Program Output

Description:
Quantity: 0
Price: 0.0

## Program 12-21 (continued)

```
Description:
Quantity: 0
Price: 0.0
Description:
Quantity: 0
Price: 0.0
Description:
Quantity: 0
Price: 0.0
Description:
Quantity: 0
Price: 0.0
```

Program 12-22 allows the user to change the contents of an individual record in the inventory file.

## Program 12-22

```
// This program allows the user to edit a specific record.
#include <iostream>
#include <fstream>
using namespace std;
const int DESC_SIZE = 31; // Description size
// Declaration of InventoryItem structure
struct InventoryItem
{
    char desc[DESC_SIZE];
    int qty;
    double price;
};
int main()
{
    InventoryItem record; // To hold an inventory record
    long recNum; // To hold a record number
    // Open the file in binary mode for input and output
    fstream inventory("Inventory.dat",
                        ios::in | ios::out | ios::binary);
    // Get the record number of the desired record.
    cout << "Which record do you want to edit? ";
    cin >> recNum;
    // Move to the record and read it.
    inventory.seekg(recNum * sizeof(record), ios::beg);
    inventory.read(reinterpret_cast<char *>(&record),
        sizeof(record));

cin.getline(record.desc, DESC_SIZE);
cout << "Quantity: ";
cin >> record.qty;
cout << "Price: ";
cin >> record.price;
    // Move back to the beginning of this record's position.
    inventory.seekp(recNum * sizeof(record), ios::beg);
    // Write the new record over the current record.
    inventory.write(reinterpret_cast<char *>(&record),
    sizeof(record));
    // Close the file.
    inventory.close();
    return 0;
```

## Program Output with Example Input Shown in Bold

Which record do you want to edit? 2 Enter
Description:
Quantity: 0
Price: 0.0
Enter the new data:
Description: Wrench Enter
Quantity: 10 Enter
Price: 4.67 Enter

## Checkpoint

12.10 Describe the difference between the seekg and the seekp functions.
12.11 Describe the difference between the te 1 g and the te 1 p functions.
12.12 Describe the meaning of the following file access flags:
ios::beg
ios::end
ios: :cur
12.13 What is the number of the first byte in a file?
12.14 Briefly describe what each of the following statements does:

```
file.seekp(100L, ios::beg);
file.seekp(-10L, ios::end);
file.seekg(-25L, ios::cur);
file.seekg(30L, ios::cur);
```

12.15 Describe the mode that each of the following statements causes a file to be opened in:

```
file.open("info.dat", ios::in | ios::out);
file.open("info.dat", ios::in | ios::app);
file.open("info.dat", ios::in | ios::out | ios::ate);
file.open("info.dat", ios::in | ios::out | ios::binary);
```

For another example of this chapter's topics, see the High Adventure Travel Part 3 Case Study, available on the Computer Science Portal at www.pearsonglobaleditions.com/gaddis.

## Review Questions and Exercises

## Short Answer

1. What capability does the fstream data type provide that the ifstream and ofstream data types do not?
2. Which file access flag do you use to open a file when you want all output written to the end of the file's existing contents?
3. Assume the file data.txt already exists, and the following statement executes. What happens to the file?
```
fstream file("data.txt", ios::out);
```

4. How can you open a binary file in both input and output modes?
5. Should file stream objects be passed to functions by value or by reference? Why?
6. Under what circumstances is a file stream object's ios: :hardfail bit set? What member function reports the state of this bit?
7. Under what circumstances is a file stream object's ios: :eofbit bit set? What member function reports the state of this bit?
8. Under what circumstances is a file stream object's ios: :badbit bit set? What member function reports the state of this bit?
9. How do you read the contents of a text file that contains whitespace characters as part of its data?
10. What arguments do you pass to a file stream object's write member function?
11. What arguments do you pass to a file stream object's read member function?
12. What type cast do you use to convert a pointer from one type to another?
13. What type of file access is preferred for accessing very large files and why?
14. How do you get the byte number of a file's current read position? How do you get the byte number of a file's current write position?
15. If a program has read to the end of a file, what must you do before using either the seekg or seekp member function?
16. How do you determine the number of bytes that a file contains?
17. How do you rewind a sequential-access file?

## Fill-in-the-Blank

18. If a file is opened using the file access flag $\qquad$ , it will be opened in append mode.
19. When a file is opened with file access flag ios::trunc, its contents are $\qquad$ .
20. The same formatting techniques used with $\qquad$ may also be used when writing data to a file.
21. The $\qquad$ function reads a line of text from a file.
22. The last character of a file is the $\qquad$ marker.
23. The $\qquad$ member function writes a single character to a file.
24. $\qquad$ files contain data that is unformatted and not necessarily stored as ASCII text.
25. Stream objects have $\qquad$ bits that indicate the condition of stream.
26. A(n) $\qquad$ is a complete set of data about a single item and is made up of
$\qquad$ .
27. In C++, $\qquad$ provide a convenient way to organize data into fields and records.
28. The $\qquad$ member function writes "raw" binary data to a file.
29. The $\qquad$ function sets values of all flags to 0 .
30. When opening a file to store structures, the $\qquad$ mode should always be used because structures can contain a mixture of data types.
31. In $\qquad$ file access, the contents of the file are read in the order they appear in the file, from the file's start to its end.
32. Accessing data in a file in a nonsequential manner is also called $\qquad$ .
33. The $\qquad$ member function moves a file's read position to a specified byte in the file.
34. The $\qquad$ member function moves a file's write position to a specified byte in the file.
35. The $\qquad$ member function returns a file's current read position.
36. The $\qquad$ member function returns a file's current write position.
37. The $\qquad$ mode flag causes an offset to be calculated from the beginning of a file.
38. The first byte of a file has the number $\qquad$ .
39. The $\qquad$ mode flag causes an offset to be calculated from the current position in the file.
40. A negative offset causes the file's read or write position to be moved $\qquad$ in the file from the position specified by the mode.

## Algorithm Workbench

41. Write a statement that defines a file stream object named places. The object will be used for both output and input.
42. Write code that uses a file stream object named birds to open a file named birds . dat in output mode. (Show how to open the file with a member function and with the file stream object definition statement.) Write "parrot" to the file and finally close it.
43. Write a function that accepts a fstream reference as an argument, reads each line of the file that is referenced by the argument, and then prints the lines on the output screen. (Use a while loop to read each line from the file.)
44. Write two statements that use a file stream object named places to open a file named places.dat. (Show how to open the file with a member function and with the file stream object definition statement) The file should be opened for both input and output.
45. Write a function that accepts a fstream reference as an argument. It should test whether the eofbit flag, the badbit flag, and the goodbit flag of the file that is referenced are set and accordingly display messages.
46. Write code that opens the file data.txt for both input and output, but first determines if the file exists. If the file does not exist, the code should create it, then open it for both input and output.
47. Write code that determines the number of bytes contained in the file associated with the file stream object dataFile.
48. Write a statement to set the write position in a random access file to the 101st byte from the current position. Write another statement to set the write position to the end of file.

## True or False

49. T F Different operating systems have different rules for naming files.
50. T F fstream objects are only capable of performing file output operations.
51. T F The statement cin.get (c) accepts a string from the keyboard and assigns it to the variable c.
52. T F ifstream objects, by default, create a file if it doesn't exist when opened.
53. T F The close() function automatically puts the end-of-file marker to a file.
54. T F Only one file can be opened for input during the execution of a program.
55. T F If a file is opened in the definition of the file stream object, no mode flags may be specified.
56. T F A file stream object's fail member function may be used to determine if the file was successfully opened.
57. T F The same output formatting techniques used with cout may also be used with file stream objects.
58. T F The function $\operatorname{bad}()$ returns 0 if the badbit flag is set.
59. T F The getline member function can be used to read text that contains whitespaces.
60. T F It is not possible to have more than one file open at once in a program.
61. T F Binary files contain unformatted data, not necessarily stored as text.
62. T F The write function is used to write data in a binary file.
63. T F The tellp member function tells a file stream object which byte to move its write position to.
64. T F When a sequential file is opened in input mode, data is read from the last byte.

## Find the Error

Each of the following programs or program segments has errors. Find as many as you can.

```
65. fstream file(ios::in | ios::out);
    file.open("info.dat");
    if (!file)
    {
        cout << "Could not open file.\n";
    }
66. ofstream file;
    file.open("info.dat", ios::in);
    if (file)
    {
        cout << "Could not open file.\n";
    }
67. fstream file("info.dat");
    if (!file)
    {
        cout << "Could not open file.ln";
    }
68. fstream dataFile("info.dat", ios:in | ios:binary);
    int x = 5;
    dataFile << x;
69. fstream dataFile("info.dat", ios:in);
    char stuff[81];
    dataFile.get(stuff);
70. fstream dataFile("info.dat", ios:in);
    char stuff[81] = "abcdefghijk1mnopqrstuvwxyz";
    dataFile.put(stuff);
71. fstream dataFile("info.dat", ios:out);
    struct Date
    {
        int month;
        int day;
        int year;
    };
    Date dt = { 4, 2, 98 };
    dataFile.write(&dt, sizeof(int));
72. fstream inFile("info.dat", ios:in);
    int x;
    inFile.seekp(5);
    inFile >> x;
```

## Programming Challenges

## 1. Display Alternate Lines of a File

Write a program that asks the user for the name of a file. If no such file exists, the program should display an error message; otherwise it should display the alternate lines in
the file (the lines with line numbers $1,3,5, \ldots$ ). The corresponding line number should be displayed before each line.

NOTE: Using an editor, you should create a simple text file that can be used to test this program.

## 2. File Display Program

Write a program that asks the user for the name of a file. The program should display the contents of the file on the screen. If the file's contents won't fit on a single screen, the program should display 24 lines of output at a time, then pause. Each time the program pauses, it should wait for the user to strike a key before the next 24 lines are displayed.

NOTE: Using an editor, you should create a simple text file that can be used to test this program.

## 3. Punch Line

Write a program that reads and prints a joke and its punch line from two different files. The first file contains a joke, but not its punch line. The second file has the punch line as its last line, preceded by "garbage." The main function of your program should open the two files then call two functions, passing each one the file it needs. The first function should read and display each line in the file it is passed (the joke file). The second function should display only the last line of the file it is passed (the punch line file). It should find this line by seeking to the end of the file and then backing up to the beginning of the last line. Data to test your program can be found in the joke.txt and punchline.txt files.

## 4. Sentences and Words in a File

Write a program that asks the user for the name of a file. The program should display the following data about the file:

- Number of words (Each word is preceded by a blank space or newline.)
- Number of sentences (Each sentence is terminated by a period.)

NOTE: Using an editor, you should create a simple text file that can be used to test this program.

## 5. Line Numbers

(This assignment could be done as a modification of the program in Programming Challenge 2.) Write a program that asks the user for the name of a file. The program should display the contents of the file on the screen. Each line of screen output should be preceded with a line number, followed by a colon. The line numbering should start at 1 . Here is an example:

1:George Rolland
2:127 Academy Street
3:Brasstown, NC 28706

If the file's contents won't fit on a single screen, the program should display 24 lines of output at a time, and then pause. Each time the program pauses, it should wait for the user to strike a key before the next 24 lines are displayed.

NOTE: Using an editor, you should create a simple text file that can be used to test this program.

## 6. Extraction of Words from a File

Write a program that asks the user for the name of a file. If the file cannot be opened, the program should display an error message; otherwise the program should display only those words in the file that have at least 10 characters in them. The program should also display the number of characters alongside each word. As an end note, the program should display the total number of words printed. The program should close the file before exiting.

NOTE: Using an editor, you should create a simple text file that can be used to test this program.

## 7. Binary Files

Write a function named storeArray that stores the contents of an array of characters in a file. This function should accept three arguments: the name of a file, a pointer to a character array, and the size of the array. The function should open the specified file in binary mode, write the contents of the array to file, and then close the file. Demonstrate the function using a program.

NOTE: Using an editor, you should create a simple text file that can be used to test this program.

## 8. Sorting a File of Records

Using an editor, create a file emp_age.txt that has two columns, where the first column records the name of employees and the second column records the age of employees. Insert at least 10 records in it.
Write a program that opens emp_age. txt in input mode and another file sort_age.txt in output mode. If the files cannot be opened, the program should display an error message and quit the program. The program should extract the first 10 records into an array of structure employee that should have the following data:
First name
Last name
Age
The program should sort the array in descending order of age and write the sorted array in the file sort_age.txt in the same format as the file emp_age.txt.

## 9. File Encryption Filter

File encryption is the science of writing the contents of a file in a secret code. Your encryption program should work like a filter, reading the contents of one file, modifying the data into a code, then writing the coded contents out to a second file. The second file will be a version of the first file, but written in a secret code.
Although there are complex encryption techniques, you should come up with a simple one of your own. For example, you could read the first file one character at a time, and add 10 to the ASCII code of each character before it is written to the second file.

## 10. File Decryption Filter

Write a program that decrypts the file produced by the program in Programming Challenge 9. The decryption program should read the contents of the coded file, restore the data to its original state, and write it to another file.

## 11. Wind Measurements

Write a program that uses a structure to store the following data for a wind observation post:

- Wind direction (North, East, South, or West)
- Speed in miles/hour
- Date (as a timestamp in seconds since $1 / 1 / 1970$ )

The user should be asked for (at least) 10 measurements. The wind direction should be input as $\mathrm{N}, \mathrm{E}, \mathrm{S}$, or W. The measurement data should be written to a file.
Input Validation: Accept only positive numbers and valid wind directions.

## 12. Wind Statistics

Write a program that reads the data in the file created by the program in Programming Challenge 11. The program should calculate and display the following information:

- The average wind speed
- The average wind speed in each direction
- The overall maximum wind speed
- The maximum wind speed in each direction
- The most prominent wind direction

## 13. Sports Training Records

Write a program that uses a structure to store the following data for a sports training program:

- Day (1-31)
- Month (1-12)
- Year (YYYY)
- Type of sport
- Distance
- Time (in seconds)

The program should have a menu that allows the user to perform the following tasks:

- Add new records to the file
- Display any record in the file
- Change any record in the file

Input Validation: The program should accept valid dates only in the range specified above. It does not need to account for leap years.
14. Sports Training Report

Write a program that reads the data in the file created by the program in Programming Challenge 13. The program should calculate and display the following data:

- The total distance of the training program
- The longest distance of any training
- The fastest training (in miles/hour)

## 15. Average Number of Words

If you have downloaded this book's source code, you will find a file named text.txt in the Chapter 12 folder. The text that is in the file is stored as one sentence per line. Write a program that reads the file's contents and calculates the average number of words per sentence.

## Group Project

16. Customer Accounts

This program should be designed and written by a team of students. Here are some suggestions:

- One student should design function main, which will call other program functions. The remainder of the functions will be designed by other members of the team.
- The requirements of the program should be analyzed so that each student is given about the same workload.
Write a program that uses a structure to store the following data about a customer account:
- Name
- Address
- City, State, and ZIP
- Telephone Number
- Account Balance
- Date of Last Payment

The structure should be used to store customer account records in a file. The program should have a menu that lets the user perform the following operations:

- Enter new records into the file
- Search for a particular customer's record and display it
- Search for a particular customer's record and delete it
- Search for a particular customer's record and change it
- Display the contents of the entire file

Input Validation: When the data for a new account is entered, be sure the user enters data for all the fields. No negative account balances should be entered.

### 13.1 Procedural and Object-Oriented Programming

CONCEPT: Procedural programming is a method of writing software. It is a programming practice centered on the procedures or actions that take place in a program. Object-oriented programming is centered around the object. Objects are created from abstract data types that encapsulate data and functions together.

There are two common programming methods in practice today: procedural programming and object-oriented programming (or OOP). Up to this chapter, you have learned to write procedural programs.

In a procedural program, you typically have data stored in a collection of variables and/or structures, coupled with a set of functions that perform operations on the data. The data and the functions are separate entities. For example, in a program that works with the geometry of a rectangle you might have the variables in Table 13-1.

Table 13-1 Variables Related to a Rectangle

| Variable Definition | Description |
| :--- | :--- |
| double width; | Holds the rectangle's width |
| double length; | Holds the rectangle's length |

In addition to the variables listed in Table 13-1, you might also have the functions listed in Table 13-2.

Table 13-2 Functions Related to a Rectangle

| Function Name | Description |
| :--- | :--- |
| setData() | Stores values in width and length |
| displayWidth() | Displays the rectangle's width |
| displayLength() | Displays the rectangle's length |
| displayArea() | Displays the rectangle's area |

Usually the variables and data structures in a procedural program are passed to the functions that perform the desired operations. As you might imagine, the focus of procedural programming is on creating the functions that operate on the program's data.
Procedural programming has worked well for software developers for many years. However, as programs become larger and more complex, the separation of a program's data and the code that operates on the data can lead to problems. For example, the data in a procedural program are stored in variables, as well as more complex structures that are created from variables. The procedures that operate on the data must be designed with those variables and data structures in mind. But what happens if the format of the data is altered? Quite often, a program's specifications change, resulting in redesigned data structures. When the structure of the data changes, the code that operates on the data must also change to accept the new format. This results in additional work for programmers and a greater opportunity for bugs to appear in the code.

This problem has helped influence the shift from procedural programming to objectoriented programming (OOP). Whereas procedural programming is centered on creating procedures or functions, object-oriented programming is centered on creating objects. An object is a software entity that contains both data and procedures. The data contained in an object are known as the object's attributes. The procedures an object performs are called member functions. The object is, conceptually, a self-contained unit consisting of attributes (data) and procedures (functions). This is illustrated in Figure 13-1.

OOP addresses the problems that can result from the separation of code and data through encapsulation and data hiding. Encapsulation refers to the combining of data and code into a single object. Data hiding refers to an object's ability to hide its data from code

Figure 13-1 An object contains data and procedures
Object

NOTE: In other programming languages, the procedures an object performs are often called methods.
that is outside the object. Only the object's member functions may directly access and make changes to the object's data. An object typically hides its data, but allows outside code to access its member functions. As shown in Figure 13-2, the object's member functions provide programming statements outside the object with indirect access to the object's data.

Figure 13-2 Only an object's member functions may access the object's data

When an object's internal data are hidden from outside code, and access to that data is restricted to the object's member functions, the data are protected from accidental corruption. In addition, the programming code outside the object does not need to know about the format or internal structure of the object's data. The code only needs to interact with the object's functions. When a programmer changes the structure of an object's internal data, he or she also modifies the object's member functions so they may properly operate on the data. The way in which outside code interacts with the member functions, however, does not change.

An everyday example of object-oriented technology is the automobile. It has a rather simple interface that consists of an ignition switch, steering wheel, gas pedal, brake pedal, and a gear shift. Vehicles with manual transmissions also provide a clutch pedal. If you want to drive an automobile (to become its user), you only have to learn to operate these elements of its interface. To start the motor, you simply turn the key in the ignition switch. What happens internally is irrelevant to the user. If you want to steer the auto to the left, you rotate the steering wheel left. The movements of all the linkages connecting the steering wheel to the front tires occur transparently.

Because automobiles have simple user interfaces, they can be driven by people who have no mechanical knowledge. This is good for the makers of automobiles because it means more people are likely to become customers. It's good for the users of automobiles because they can learn just a few simple procedures and operate almost any vehicle.

These are also valid concerns in software development. A real-world program is rarely written by only one person. Even the programs you have created so far weren't written entirely by you. If you incorporated C++ library functions, or objects like cin and cout, you used code written by someone else. In the world of professional software development, programmers commonly work in teams, buy and sell their code, and collaborate on projects. With OOP, programmers can create objects with powerful engines tucked away "under the hood," protected by simple interfaces that safeguard the object's algorithms.

## Object Reusability

In addition to solving the problems of code/data separation, the use of OOP has also been encouraged by the trend of object reusability. An object is not a stand-alone program, but is used by programs that need its service. For example, Sharon is a programmer who has developed an object for rendering 3D images. She is a math whiz and knows a lot about computer graphics, so her object is coded to perform all the necessary 3D mathematical operations and handle the computer's video hardware. Tom, who is writing a program for an architectural firm, needs his application to display 3D images of buildings. Because he is working under a tight deadline and does not possess a great deal of knowledge about computer graphics, he can use Sharon's object to perform the 3D rendering (for a small fee, of course!).

## Classes and Objects

Now let's discuss how objects are created in software. Before an object can be created, it must be designed by a programmer. The programmer determines the attributes and functions that are necessary then creates a class. A class is code that specifies the attributes and
member functions that a particular type of object may have. Think of a class as a "blueprint" from which objects may be created. It serves a similar purpose as the blueprint for a house. The blueprint itself is not a house, but is a detailed description of a house. When we use the blueprint to build an actual house, we could say we are building an instance of the house described by the blueprint. If we so desire, we can build several identical houses from the same blueprint. Each house is a separate instance of the house described by the blueprint. This idea is illustrated in Figure 13-3.

Figure 13-3 A blueprint describes a house
Blueprint that describes a house.

Instances of the house described by the blueprint.

So, a class is not an object, but it is a description of an object. When the program is running, it uses the class to create, in memory, as many objects of a specific type as needed. Each object that is created from a class is called an instance of the class.

For example, Jessica is an entomologist (someone who studies insects), and she also enjoys writing computer programs. She designs a program to catalog different types of insects. As part of the program, she creates a class named Insect, which specifies attributes and member functions for holding and manipulating data common to all types of insects. The Insect class is not an object, but a specification that objects may be created from. Next, she writes programming statements that create a housefly object, which is an instance of the Insect class. The housefly object is an entity that occupies computer memory and stores data about a housefly. It has the attributes and member functions specified by the Insect class. Then she writes programming statements that create a mosquito object. The mosquito object is also an instance of the Insect class. It has its own area in memory and stores data about a mosquito. Although the housefly and mosquito objects are two separate entities in the computer's memory, they were both created from the Insect class. This means that each of the objects has the attributes and member functions described by the Insect class. This is illustrated in Figure 13-4.

Figure 13-4 Instances of a class

The Insect class describes the attributes and functions that a particular type of object may have.

The housefly object is an instance of the Insect class. It has the attributes and functions described by the Insect class.

The mosquito object is an instance of the Insect class. It has the attributes and functions described by the Insect class.

At the beginning of this section, we discussed how a procedural program that works with rectangles might have variables to hold the rectangle's width and length and separate functions to do things like store values in the variables and make calculations. The program would pass the variables to the functions as needed. In an object-oriented program, we would create a Rectang1e class, which would encapsulate the data (width and length) and the functions that work with the data. Figure $13-5$ shows a representation of such a class.

## Figure 13-5 A class encapsulates data and functions

```
Member Variables
    double width;
    doub7e length;
Member Functions
    void setWidth(double w)
    { ... function code ...}
    void setLength(double len)
    { ... function code ...}
    double getWidth()
    { ... function code ...}
    double getLength()
    { ... function code ...}
    double getArea()
    { ... function code ...}
```

In the object-oriented approach, the variables and functions are all members of the Rectangle class. When we need to work with a rectangle in our program, we create a Rectangle object, which is an instance of the Rectangle class. When we need to perform an operation on the Rectangle object's data, we use that object to call the appropriate member function. For example, if we need to get the area of the rectangle, we use the object to call the getArea member function. The getArea member function would be designed to calculate the area of that object's rectangle and return the value.

## Using a Class You Already Know

Before we go any further, let's review the basics of a class that you have already learned something about: the string class. First, recall that you must have the following \#include directive in any program that uses the string class:

```
#include <string>
```

This is necessary because the string class is declared in the <string> header file. Next, you can define a string object with a statement such as

```
string cityName;
```

This creates a string object named cityName. The cityName object is an instance of the string class.
Once a string object has been created, you can store data in it. Because the string class is designed to work with the assignment operator, you can assign a string literal to a string object. Here is an example:

```
cityName = "Charleston";
```

After this statement executes, the string "Charleston" will be stored in the cityName object. "Charleston" will become the object's data.

The string class specifies numerous member functions that perform operations on the data that a string object holds. For example, it has a member function named length, which returns the length of the string stored in a string object. The following code demonstrates:

```
string cityName; // Create a string object named cityName
int strSize; // To hold the length of a string
cityName = "Charleston"; // Assign "Charleston" to cityName
strSize = cityName.length(); // Store the string length in strSize
```

The last statement calls the length member function, which returns the length of a string. The expression cityName. length () returns the length of the string stored in the cityName object. After this statement executes, the strSize variable will contain the value 10 , which is the length of the string "Charleston".

The string class also specifies a member function named append, which appends an additional string onto the string already stored in an object. The following code demonstrates this:

```
string cityName;
cityName = "Charleston";
cityName.append(" South Carolina");
```

In the second line, the string "Charleston" is assigned to the cityName object. In the third line, the append member function is called and " South Carolina" is passed as an argument. The argument is appended to the string that is already stored in cityName. After this statement executes, the cityName object will contain the string "Charleston South Carolina".

### 13.2 Introduction to Classes

CONCEPT: In C++, the class is the construct primarily used to create objects.
A class is similar to a structure. It is a data type defined by the programmer, consisting of variables and functions. Here is the general format of a class declaration:

```
class ClassName
{
    declaration;
    // ... more declarations
    // may follow...
};
```

The declaration statements inside a class declaration are for the variables and functions that are members of that class. For example, the following code declares a class named Rectangle with two member variables: width and length.

```
class Rectangle
{
    double width;
    double length;
}; // Don't forget the semicolon.
```

There is a problem with this class, however. Unlike structures, the members of a class are private by default. Private class members cannot be accessed by programming statements outside the class. So, no statements outside this Rectangle class can access the width and length members.

Recall from our earlier discussion on object-oriented programming that an object can perform data hiding, which means that critical data stored inside the object are protected from code outside the object. In C++, a class's private members are hidden and can be accessed only by functions that are members of the same class. A class's public members may be accessed by code outside the class.

## Access Specifiers

C++ provides the key words private and public, which you may use in class declarations. These key words are known as access specifiers because they specify how class members may be accessed. The following is the general format of a class declaration that uses the private and public access specifiers:

```
class ClassName
{
    private:
        // Declarations of private
        // members appear here.
    public:
        // Declarations of public
        // members appear here.
};
```

Notice the access specifiers are followed by a colon (:) then followed by one or more member declarations. In this general format, the private access specifier is used first. All of the declarations that follow it, up to the public access specifier, are for private members. Then, all of the declarations that follow the public access specifier are for public members.

## Public Member Functions

To allow access to a class's private member variables, you create public member functions that work with the private member variables. For example, consider the Rectangle class. To allow access to a Rectangle object's width and length member variables, we will add the member functions listed in Table 13-3.

Table 13-3 The Rectang1e Class's Member Functions

| Member Function | Description |
| :--- | :--- |
| setWidth | This function accepts an argument, which is assigned to the width <br> member variable. |
| setLength | This function accepts an argument, which is assigned to the length <br> member variable. |
| getWidth | This function returns the value stored in the width member variable. <br> getLength |
| getArea | This function returns the value stored in the length member variable. <br> This function returns the product of the width member variable multiplied <br> by the length member variable. This value is the area of the rectangle. |

For the moment, we will not actually define the functions described in Table 13-3. We leave that for later. For now, we will only include declarations, or prototypes, for the functions in the class declaration.

```
class Rectangle
{
    private:
        double width;
        double length;
    public:
        void setWidth(doub1e);
        void setLength(double);
        double getWidth() const;
        double getLength() const;
        double getArea() const;
};
```

In this declaration, the member variables width and length are declared as private, which means they can be accessed only by the class's member functions. The member functions, however, are declared as public, which means they can be called from statements outside the class. If code outside the class needs to store a width or a length in a Rectangle object, it must do so by calling the object's setWidth or setLength member functions. Likewise, if code outside the class needs to retrieve a width or length stored in a Rectangle object, it must do so with the object's getWidth or getLength member functions. These public functions provide an interface for code outside the class to use Rectangle objects.

NOTE: Even though the default access of a class is private, it's still a good idea to use the private key word to explicitly declare private members. This clearly documents the access specification of all the members of the class.

## Using const with Member Functions

Notice the key word const appears in the declarations of the getWidth, getLength, and getArea member functions, as shown here:

```
double getWidth() const;
double getLength() const;
double getArea() const;
```

When the key word const appears after the parentheses in a member function declaration, it specifies that the function will not change any data stored in the calling object. If you inadvertently write code in the function that changes the calling object's data, the compiler will generate an error. As you will see momentarily, the const key word must also appear in the function header.

## Placement of public and private Members

There is no rule requiring you to declare private members before public members. The Rectangle class could be declared as follows:

```
class Rectangle
{
    public:
        void setWidth(double);
        void setLength(double);
        double getWidth() const;
        double getLength() const;
        double getArea() const;
    private:
        double width;
        double length;
};
```

In addition, it is not required that all members of the same access specification be declared in the same place. Here is yet another declaration of the Rectangle class.

```
class Rectangle
{
    private:
        double width;
    public:
        void setWidth(double);
        void setLength(double);
        double getWidth() const;
        double getLength() const;
        double getArea() const;
    private:
        double length;
};
```

Although C++ gives you freedom in arranging class member declarations, you should adopt a consistent standard. Most programmers choose to group member declarations of the same access specification together.

NOTE: Notice in our example the first character of the class name is written in uppercase. This is not required, but serves as a visual reminder that the class name is not a variable name.

## Defining Member Functions

The Rectangle class declaration contains declarations or prototypes for five member functions: setWidth, setLength, getWidth, getLength, and getArea. The definitions of these functions are written outside the class declaration.

```
//*************************************************************
// setWidth assigns its argument to the private member width.
/|*****************************************************************
void Rectangle::setWidth(double w)
{
    width = w;
}
//**************************************************************
// setLength assigns its argument to the private member length.
|/|*******************************************************************
void Rectangle::setLength(double len)
{
    length = len;
}
//************************************************************
// getWidth returns the value in the private member width.
//************************************************************
double Rectangle::getWidth() const
{
    return width;
}
//************************************************************
// getLength returns the value in the private member length. *
//*************************************************************
double Rectangle::getLength() const
{
    return length;
}
```

```
//*****************************************************
// getArea returns the product of width times length. *
/|*******************************************************
double Rectangle::getArea() const
{
    return width * length;
}
```

In each function definition, the following precedes the name of each function:
Rectangle::
The two colons are called the scope resolution operator. When Rectangle:: appears before the name of a function in a function header, it identifies the function as a member of the Rectangle class.
Here is the general format of the function header of any member function defined outside the declaration of a class:

ReturnType C7assName::functionName(ParameterList)
In the general format, ReturnType is the function's return type. ClassName is the name of the class of which the function is a member. functionName is the name of the member function. ParameterList is an optional list of parameter variable declarations.

WARNING! Remember, the class name and scope resolution operator extends the name of the function. They must appear after the return type and immediately before the function name in the function header. The following would be incorrect:

```
Rectangle::double getArea() //Incorrect!
```

In addition, if you leave the class name and scope resolution operator out of a member function's header, the function will not become a member of the class.

```
double getArea() // Not a member of the Rectangle class!
```

## Accessors and Mutators

As mentioned earlier, it is a common practice to make all of a class's member variables private, and to provide public member functions for accessing and changing them. This ensures that the object owning the member variables is in control of all changes being made to them. A member function that gets a value from a class's member variable but does not change it is known as an accessor. A member function that assigns a value to a member variable is known as a mutator. In the Rectangle class, the member functions getLength and getWidth are accessors, and the member functions setLength and setWidth are mutators.

Some programmers refer to mutators as setter functions because they set the value of an attribute, and accessors as getter functions because they get the value of an attribute.

## Using const with Accessors

Notice the key word const appears in the headers of the getWidth, getLength, and getArea member functions, as shown here:

```
double Rectang1e::getWidth() const
double Rectangle::getLength() const
double Rectangle::getArea() const
```

Recall that these functions were also declared in the class with the const key word. When you mark a member function as const, the const key word must appear in both the declaration and the function header.

In essence, when you mark a member function as const, you are telling the compiler that the calling object is a constant. The compiler will generate an error if you inadvertently write code in the function that changes the calling object's data. Because this decreases the chances of having bugs in your code, it is a good practice to mark all accessor functions as const.

## The Importance of Data Hiding

As a beginning student, you might be wondering why you would want to hide the data that is inside the classes you create. As you learn to program, you will be the user of your own classes, so it might seem that you are putting forth a great effort to hide data from yourself. If you write software in industry, however, the classes that you create will be used as components in large software systems; programmers other than yourself will use your classes. By hiding a class's data and allowing it to be accessed through only the class's member functions, you can better ensure that the class will operate as you intended.

### 13.3 Defining an Instance of a Class

CONCEPT: Class objects must be defined after the class is declared.

Like structure variables, class objects are not created in memory until they are defined. This is because a class declaration by itself does not create an object, but is merely the description of an object. We can use it to create one or more objects, which are instances of the class.

Class objects are created with simple definition statements, just like variables. Here is the general format of a simple object definition statement:

```
ClassName objectName;
```

In the general format, ClassName is the name of a class, and objectName is the name we are giving the object.
For example, the following statement defines box as an object of the Rectangle class:
Rectangle box;
Defining a class object is called the instantiation of a class. In this statement, box is an instance of the Rectangle class.

## Accessing an Object's Members

The box object we previously defined is an instance of the Rectangle class. Suppose we want to change the value in the box object's width variable. To do so, we must use the box object to call the setWidth member function, as shown here:

```
box.setWidth(12.7);
```

Just as you use the dot operator to access a structure's members, you use the dot operator to call a class's member functions. This statement uses the box object to call the setWidth member function, passing 12.7 as an argument. As a result, the box object's width variable will be set to 12.7 . Here are other examples of statements that use the box object to call member functions:

```
box.setLength(4.8); // Set box's length to 4.8.
x = box.getWidth(); /l Assign box's width to x.
cout << box.getLength(); // Display box's length.
cout << box.getArea(); // Display box's area.
```

NOTE: Notice inside the Rectangle class's member functions, the dot operator is not used to access any of the class's member variables. When an object is used to call a member function, the member function has direct access to that object's member variables.

## A Class Demonstration Program

Program 13-1 is a complete program that demonstrates the Rectangle class.

## Program 13-1

```
// This program demonstrates a simple class.
#include <iostream>
using namespace std;
// Rectangle class declaration.
class Rectangle
{
    private:
        double width;
        double length;
        public:
            void setWidth(double);
            void setLength(double);
            double getWidth() const;
            double getLength() const;
            double getArea() const;
};
//**************************************************
// setWidth assigns a value to the width member.
/|***************************************************
void Rectangle::setWidth(double w)
```

```
        width = w;
}
//****************************************************
// setLength assigns a value to the length member.
//******************************************************
void Rectang1e::setLength(doub1e 1en)
{
        1ength = 1en;
}
//****************************************************
// getWidth returns the value in the width member.
//******************************************************
doub1e Rectang1e::getWidth() const
{
        return width;
}
/|*****************************************************
// getLength returns the value in the length member.
//*******************************************************
double Rectangle::getLength() const
{
        return length;
}
//**********************************************************
// getArea returns the product of width times length.
//*******************************************************
doub1e Rectang1e::getArea() const
{
        return width * length;
    }
|/*******************************************************
// Function main
//******************************************************
    int main()
    {
        Rectangle box; // Define an instance of the Rectangle class
        double rectWidth; // Local variable for width
        double rectLength; // Local variable for length
        // Get the rectangle's width and length from the user.
        cout << "This program will calculate the area of a\n";
        cout << "rectangle. What is the width? ";
```

## Program 13-1 (continued)

```
77 cin >> rectWidth;
78 cout << "What is the length? ";
79 cin >> rectLength;
80
81
82
83 box setWidth(rectWidth)
box.setWid
84 box.setLength(rectLength);
85
86
87
88
89
90
91
    // Display the rectangle's data.
cout << "Here is the rectangle's data:\n";
cout << "Width: " << box.getWidth() << end1;
cout << "Length: " << box.getLength() << end1;
cout << "Area: " << box.getArea() << endl;
return 0;
}
```

## Program Output with Example Input Shown in Bold

This program will calculate the area of a
rectangle. What is the width? 10 Enter
What is the length? 5 Enter
Here is the rectangle's data:
Width: 10
Length: 5
Area: 50

The Rectangle class declaration, along with the class's member functions, appears in lines 6 through 62. Inside the main function, in line 70, the following statement creates a Rectangle object named box:

Rectangle box;
The box object is illustrated in Figure 13-6. Notice the width and length member variables do not yet hold meaningful values. An object's member variables are not automatically initialized to 0 . When an object's member variable is first created, it holds whatever random value happens to exist at the variable's memory location. We commonly refer to such a random value as "garbage."

Figure 13-6 State of the box object
The box object when first created

In lines 75 through 79 , the program prompts the user to enter the width and length of a rectangle. The width that is entered is stored in the rectWidth variable, and the length that is entered is stored in the rectLength variable. In line 83 the following statement uses
the box object to call the setWidth member function, passing the value of the rectWidth variable as an argument:

```
box.setWidth(rectWidth);
```

This sets box's width member variable to the value in rectWidth. Assuming rectWidth holds the value 10 , Figure $13-7$ shows the state of the box object after this statement executes.

Figure 13-7 State of the box object
The box object with width set to 10

In line 84 , the following statement uses the box object to call the setLength member function, passing the value of the rectLength variable as an argument:

```
box.setLength(rectLength);
```

This sets box's length member variable to the value in rectLength. Assuming rectLength holds the value 5, Figure 13-8 shows the state of the box object after this statement executes.

Figure 13-8 State of the box object
The box object with width set to 10 and 1 ength set to 5

Lines 88,89 , and 90 use the box object to call the getWidth, getLength, and getArea member functions, displaying their return values on the screen.

NOTE: Figures 13-6 through 13-8 show the state of the box object at various times during the execution of the program. An object's state is simply the data that is stored in the object's attributes at any given moment.

Program 13-1 creates only one Rectang1e object. It is possible to create many instances of the same class, each with its own data. For example, Program 13-2 creates three Rectang1e objects, named kitchen, bedroom, and den. Note lines 6 through 62 have been left out of the listing because they contain the Rectangle class declaration and the definitions for the class's member functions. These lines are identical to those same lines in Program 13-1.

## Program 13-2

```
// This program creates three instances of the Rectangle class.
#include <iostream>
using namespace std;
// Rectangle class declaration.
```

Lines 6 through 62 have been left out.

63
64
65
66
67
68

```
//******************************************************
// Function main
//******************************************************
int main()
{
\begin{tabular}{ll} 
double number; & // To hold a number \\
double totalArea; & // The total area \\
Rectangle kitchen; & // To hold kitchen dimensions \\
Rectangle bedroom; & // To hold bedroom dimensions \\
Rectangle den; & // To hold den dimensions
\end{tabular}
```

    // Get the kitchen dimensions.
    cout << "What is the kitchen's length? ";
    cin >> number; // Get the length
    kitchen.setLength(number); // Store in kitchen object
    cout << "What is the kitchen's width? ";
    cin >> number; // Get the width
    kitchen.setWidth(number); // Store in kitchen object
    // Get the bedroom dimensions.
    cout << "What is the bedroom's length? ";
    cin >> number; // Get the length
    bedroom.setLength(number); // Store in bedroom object
    cout << "What is the bedroom's width? ";
    cin >> number; // Get the width
    bedroom.setWidth(number); // Store in bedroom object
    // Get the den dimensions.
    cout << "What is the den's length? ";
    cin >> number; // Get the length
    den.setLength(number); // Store in den object
    cout << "What is the den's width? ";
    cin >> number; // Get the width
    den.setWidth(number); // Store in den object
    // Calculate the total area of the three rooms.
    totalArea \(=\) kitchen.getArea() + bedroom.getArea() +
        den.getArea();
    // Display the total area of the three rooms.
    cout << "The total area of the three rooms is "
        << totalArea << endl;
    ```
108 return 0;
109 }
```

## Program Output with Example Input Shown in Bold

```
What is the kitchen's length? 10 Enter
What is the kitchen's width? 14 Enter
What is the bedroom's length? 15 Enter
What is the bedroom's width? 12 Enter
What is the den's length? 20 Enter
What is the den's width? }30\mathrm{ Enter
The total area of the three rooms is 920
```

In lines 72, 73, and 74, the following code defines three Rectangle variables. This creates three objects, each an instance of the Rectangle class:

```
Rectangle kitchen; // To hold kitchen dimensions
Rectangle bedroom; // To hold bedroom dimensions
Rectangle den; // To hold den dimensions
```

In the example output, the user enters 10 and 14 as the length and width of the kitchen, 15 and 12 as the length and width of the bedroom, and 20 and 30 as the length and width of the den. Figure 13-9 shows the states of the objects after these values are stored in them.

Figure 13-9 State of the kitchen, bedroom, and den objects

| The kitchen object | The bedroom object |
| :--- | :--- | The den object

Notice from Figure 13-9 each instance of the Rectangle class has its own length and width variables. Every instance of a class has its own set of member variables that can hold their own values. The class's member functions can perform operations on specific instances of the class. For example, look at the following statement in line 79 of Program 13-2:

```
kitchen.setLength(number);
```

This statement calls the setLength member function, which stores a value in the kitchen object's length variable. Now look at the following statement in line 87 :

```
bedroom.setLength(number);
```

This statement also calls the setLength member function, but this time it stores a value in the bedroom object's length variable. Likewise, the following statement in line 95 calls the setLength member function to store a value in the den object's length variable:

```
den.setLength(number);
```

The setLength member function stores a value in a specific instance of the Rectangle class. All of the other Rectangle class member functions work in a similar way. They access one or more member variables of a specific Rectangle object.

## Avoiding Stale Data

In the Rectangle class, the getLength and getWidth member functions return the values stored in member variables, but the getArea member function returns the result of a calculation. You might be wondering why the area of the rectangle is not stored in a member variable, like the length and the width. The area is not stored in a member variable because it could potentially become stale. When the value of an item is dependent on other data and that item is not updated when the other data are changed, it is said that the item has become stale. If the area of the rectangle were stored in a member variable, the value of the member variable would become incorrect as soon as either the length or width member variables changed.

When designing a class, you should take care not to store in a member variable calculated data that could potentially become stale. Instead, provide a member function that returns the result of the calculation.

## Pointers to Objects

You can also define pointers to class objects. For example, the following statement defines a pointer variable named rectPtr:

```
Rectangle *rectPtr = nullptr;
```

The rectPtr variable is not an object, but it can hold the address of a Rectangle object. The following code shows an example:

```
Rectangle myRectangle; // A Rectangle object
Rectangle *rectPtr = nullptr; // A Rectangle pointer
rectPtr = &myRectangle; // rectPtr now points to myRectangle
```

The first statement creates a Rectangle object named myRectangle. The second statement creates a Rectangle pointer named rectPtr. The third statement stores the address of the myRectangle object in the rectPtr pointer. This is illustrated in Figure 13-10.

Figure 13-10 rectPtr points to the myRectangle object

The rectPtr pointer can then be used to call member functions by using the $->$ operator. The following statements show examples:

```
rectPtr->setWidth(12.5);
rectPtr->setLength(4.8);
```

The first statement calls the setWidth member function, passing 12.5 as an argument. Because rectPtr points to the myRectangle object, this will cause 12.5 to be stored in the myRectangle object's width variable. The second statement calls the setLength member function, passing 4.8 as an argument. This will cause 4.8 to be stored in the myRectangle
object's 1 ength variable. Figure 13-11 shows the state of the myRectang1e object after these statements have executed.

## Figure 13-11 State of the myRectang1e object

Class object pointers can be used to dynamically allocate objects. The following code shows an example:

```
// Define a Rectangle pointer.
Rectangle *rectPtr = nullptr;
// Dynamically allocate a Rectangle object.
rectPtr = new Rectangle;
// Store values in the object's width and length.
rectPtr->setWidth(10.0);
rectPtr->setLength(15.0);
// Delete the object from memory.
de1ete rectPtr;
rectPtr = nullptr;
```

Line 2 defines rectPtr as a Rectangle pointer. Line 5 uses the new operator to dynamically allocate a Rectang1e object and assign its address to rectPtr. Lines 8 and 9 store values in the dynamically allocated object's width and length variables. Figure 13-12 shows the state of the dynamically allocated object after these statements have executed.

Figure 13-12 rectPtr points to a dynamically allocated Rectangle object

Line 12 deletes the object from memory, and line 13 stores the address 0 in rectPtr. Recall from Chapter 9 that this prevents code from inadvertently using the pointer to access the area of memory that has been freed. It also prevents errors from occurring if delete is accidentally called on the pointer again.

Program 13-3 is a modification of Program 13-2. In this program, kitchen, bedroom, and den are Rectangle pointers. They are used to dynamically allocate Rectangle objects. The output is the same as Program 13-2.

## Program 13-3

```
// This program creates three instances of the Rectangle class.
#include <iostream>
using namespace std;
// Rectangle class declaration.
```

    delete den;
    kitchen = nullptr; // Make kitchen a null pointer.
    bedroom = nullptr; // Make bedroom a null pointer.
    den = nullptr; // Make den a null pointer.
        return 0;
```

\}

## Using Smart Pointers to Allocate Objects

Chapter 9 discussed the smart pointer data type unique_ptr, which was introduced in C++ 11. Recall from Chapter 9 that you can use a unique_ptr to dynamically allocate memory, and not worry about deleting the memory when you are finished using it. A unique_ptr automatically deletes a chunk of dynamically allocated memory when the memory is no longer being used. This helps to prevent memory leaks from occurring.

To use the unique_ptr data type, you must \#include the <memory> header file with the following directive:

```
#include <memory>
```

Here is an example of the syntax for defining a unique_ptr that points to a dynamically allocated Rectangle object:

```
unique_ptr<Rectangle> rectanglePtr(new Rectangle);
```

This statement defines a unique_ptr named rectanglePtr that points to a dynamically allocated Rectangle object. Here are some details about the statement:

- The notation <Rectangle> that appears immediately after unique_ptr indicates that the pointer can point to a Rectangle.
- The name of the pointer is rectanglePtr.
- The expression new Rectangle that appears inside the parentheses allocates a chunk of memory to hold a Rectangle. The address of the chunk of memory will be assigned to the rectanglePtr pointer.

Once you have defined a unique_ptr, you can use it in the same way as a regular pointer. This is demonstrated in Program 13-4. This is a revised version of Program 13-3, modified to use unique_ptrs instead of regular pointers. The output is the same as Programs 13-2 and 13-3.

## Program 13-4

```
// This program uses smart pointers to allocate three
// instances of the Rectangle class.
#include <iostream>
#include <memory>
using namespace std;
// Rectangle class declaration.
```

Lines 8 through 64 have been left out.

```
/|******************************************************
// Function main
/ /*
int main()
{
    double number; // To hold a number
    double totalArea; // The total area
    // Dynamically allocate the objects.
    unique_ptr<Rectangle> kitchen(new Rectangle);
    unique_ptr<Rectangle> bedroom(new Rectangle);
    unique_ptr<Rectangle> den(new Rectangle);
    // Get the kitchen dimensions.
    cout << "What is the kitchen's length? ";
    cin >> number; // Get the length
    kitchen->setLength(number); // Store in kitchen object
    cout << "What is the kitchen's width? ";
    cin >> number; // Get the width
    kitchen->setWidth(number); // Store in kitchen object
    // Get the bedroom dimensions.
    cout << "What is the bedroom's length? ";
    cin >> number; // Get the length
    bedroom->setLength(number); // Store in bedroom object
    cout << "What is the bedroom's width? ";
    cin >> number; // Get the width
    bedroom->setWidth(number); // Store in bedroom object
    // Get the den dimensions.
    cout << "What is the den's length? ";
    cin >> number; // Get the length
    den->setLength(number); // Store in den object
    cout << "What is the den's width? ";
    cin >> number; // Get the width
    den->setWidth(number); // Store in den object
    // Calculate the total area of the three rooms.
    totalArea = kitchen->getArea() + bedroom->getArea() +
        den->getArea();
```

        // Display the total area of the three rooms.
        cout << "The total area of the three rooms is "
        << totalArea << endl;
        return 0;
    \}

In line 4, we have a \#include directive for the <memory> header file. Lines 76 through 78 define three unique_ptrs, named kitchen, bedroom, and den. Each of these points to a dynamically allocated Rectangle. Notice there are no delete statements at the end of the main function to free the dynamically allocated memory. It is unnecessary to delete the dynamically allocated Rectangle objects because the smart pointer will automatically delete them as the function comes to an end.

## Checkpoint

13.1 True or False: You must declare all private members of a class before the public members.
13.2 Assume RetailItem is the name of a class, and the class has a void member function named setPrice, which accepts a double argument. Which of the following shows the correct use of the scope resolution operator in the member function definition?
A) RetailItem::void setPrice(double p)
B) void RetailItem::setPrice (double p)
13.3 An object's private member variables are accessed from outside the object by which of the following?
A) public member functions
B) any function
C) the dot operator
D) the scope resolution operator
13.4 Assume RetailItem is the name of a class, and the class has a void member function named setPrice, which accepts a double argument. If soap is an instance of the Retailitem class, which of the following statements properly uses the soap object to call the setPrice member function?
A) RetailItem::setPrice(1.49);
B) soap::setPrice(1.49);
C) soap.setPrice(1.49) ;
D) soap:setPrice(1.49);
13.5 Complete the following code skeleton to declare a class named Date. The class should contain variables and functions to store and retrieve a date in the form 4/2/2018.
class Date
\{ private: public:
\}

### 13.4 Why Have Private Members?

CONCEPT: In object-oriented programming, an object should protect its important data by making it private and providing a public interface to access that data.

You might be questioning the rationale behind making the member variables in the Rectang1e class private. You might also be questioning why member functions were defined for such simple tasks as setting variables and getting their contents. After all, if the member variables were declared as public, the member functions wouldn't be needed.

As mentioned earlier in this chapter, classes usually have variables and functions that are meant only to be used internally. They are not intended to be accessed by statements outside the class. This protects critical data from being accidentally modified or used in a way that might adversely affect the state of the object. When a member variable is declared as private, the only way for an application to store values in the variable is through a public member function. Likewise, the only way for an application to retrieve the contents of a private member variable is through a public member function. In essence, the public members become an interface to the object. They are the only members that may be accessed by any application that uses the object.
In the Rectangle class, the width and length member variables hold critical data. Therefore they are declared as private, and an interface is constructed with public member functions. If a program creates a Rectangle object, the program must use the setWidth and getWidth member functions to access the object's width member. To access the object's 1 ength member, the program must use the setLength and getLength member functions. This idea is illustrated in Figure 13-13.

Figure 13-13 Private member variables may be accessed only by member functions

The public member functions can be written to filter out invalid data. For example, look at the following version of the setWidth member function:

```
void Rectangle::setWidth(double w)
{
    if (w >= 0)
        width = w;
```

```
    else
    {
        cout << "Invalid width\n";
        exit(EXIT_FAILURE);
    }
}
```

Notice this version of the function doesn't just assign the parameter value to the width variable. It first tests the parameter to make sure it is 0 or greater. If a negative number was passed to the function, an error message is displayed, then the standard library function exit is called to abort the program. The setLength function could be written in a similar way:

```
void Rectangle::setLength(double len)
{
    if (len >= 0)
        length = len;
    else
    {
        cout << "Invalid length\n";
        exit(EXIT_FAILURE);
    }
}
```

The point being made here is that mutator functions can do much more than simply store values in attributes. They can also validate those values to ensure that only acceptable data is stored in the object's attributes. Keep in mind, however, that calling the exit function, as we have done in these examples, is not the best way to deal with invalid data. In reality, you would not design a class to abort the entire program just because invalid data were passed to a mutator function. In Chapter 15, we will discuss exceptions, which provide a much better way for classes to handle errors. Until we discuss exceptions, however, we will keep our code simple by using only rudimentary data validation techniques.

### 13.5 Focus on Software Engineering: Separating Class Specification from Implementation

CONCEPT: Usually class declarations are stored in their own header files. Member function definitions are stored in their own .cpp files.

In the programs we've looked at so far, the class declaration, member function definitions, and application program are all stored in one file. A more conventional way of designing C++ programs is to store class declarations and member function definitions in their own separate files. Typically, program components are stored in the following fashion:

- Class declarations are stored in their own header files. A header file that contains a class declaration is called a class specification file. The name of the class specification file is usually the same as the name of the class, with a .h extension. For example, the Rectangle class would be declared in the file Rectangle.h.
- The member function definitions for a class are stored in a separate .cpp file called the class implementation file. The file usually has the same name as the class, with the .cpp extension. For example, the Rectangle class's member functions would be defined in the file Rectangle.cpp.
- Any program that uses the class should \#include the class's header file. The class's .cpp file (which contains the member function definitions) should be compiled and linked with the main program. This process can be automated with a project or make utility. Integrated development environments such as Visual Studio also provide the means to create the multi-file projects.

Let's see how we could rewrite Program 13-1 using this design approach. First, the Rectangle class declaration would be stored in the following Rectangle.h file. (This file can be found in the Student Source Code Folder Chapter 13\Rectangle Version 1.)

## Contents of Rectang1e.h (Version 1)

```
    // Specification file for the Rectangle class.
    #ifndef RECTANGLE_H
    #define RECTANGLE_H
    // Rectangle class declaration.
    class Rectangle
{
        private:
            double width;
            double length;
        pub1ic:
            void setWidth(double);
            void setLength(double);
            double getWidth() const;
            double getLength() const;
            double getArea() const;
};
#endif
```

This is the specification file for the Rectangle class. It contains only the declaration of the Rectangle class. It does not contain any member function definitions. When we write other programs that use the Rectangle class, we can have an \#include directive that includes this file. That way, we won't have to write the class declaration in every program that uses the Rectangle class.

This file also introduces two new preprocessor directives: \#i fndef and \#endi f. The \#ifndef directive that appears in line 2 is called an include guard. It prevents the header file from accidentally being included more than once. When your main program file has an \#include directive for a header file, there is always the possibility that the header file will have an \#include directive for a second header file. If your main program file also has an \#include directive for the second header file, then the preprocessor will include the second header file twice. Unless an include guard has been written into the second header file, an error will occur because the compiler will process the declarations in the second header file twice. Let's see how an include guard works.

The word ifndef stands for "if not defined." It is used to determine whether a specific constant has not been defined with a \#define directive. When the Rectangle.h file is being compiled, the \#i fndef directive checks for the existence of a constant named RECTANGLE_H. If the constant has not been defined, it is immediately defined in line 3 , and the rest of the file is included. If the constant has been defined, it means the file has already been included. In that case, everything between the \#ifndef and \#endif directives is skipped. This is illustrated in Figure 13-14.

## Figure 13-14 How an include guard works

```
#ifndef RECTANGLE_H
```

\#ifndef RECTANGLE_H
\#define RECTANGLE_H
\#define RECTANGLE_H
class Rectangle
class Rectangle
{
{
// Member dec7arations
// Member dec7arations
// appear here.
// appear here.
};
};
\#endif

```
#endif
```

Next, we need an implementation file that contains the class's member function definitions. The implementation file for the Rectangle class is Rectangle.cpp. (This file can be found in the Student Source Code Folder Chapter 13\Rectangle Version 1.)

## Contents of Rectangle.cpp (Version 1)

```
// Implementation file for the Rectangle class.
#include "Rectangle.h" // Needed for the Rectangle class
#include <iostream> // Needed for cout
#include <cstdlib> // Needed for the exit function
using namespace std;
//*************************************************************
// setWidth sets the value of the member variable width. *
//************************************************************
```

10

```
void Rectangle::setWidth(double w)
{
    if (w >= 0)
        width = w;
        else
        {
        cout << "Invalid width\n";
        exit(EXIT_FAILURE);
    }
}
//**************************************************************
// setLength sets the value of the member variable length.
//*************************************************************
void Rectang1e::setLength(double 1en)
{
    if (len >= 0)
            1ength = 1en;
        else
    {
            cout << "Invalid length\n";
            exit(EXIT_FAILURE);
    }
}
//*************************************************************
// getWidth returns the value in the member variable width. *
//****************************************************************
doub1e Rectang1e::getWidth() const
{
    return width;
}
//*****************************************************************
// getLength returns the value in the member variable length.
/|*****************************************************************
double Rectangle::getLength() const
{
    return length;
}
l/**************************************************************
// getArea returns the product of width times length.
/|*******************************************************************
double Rectangle::getArea() const
{
    return width * length;
}
```

Look at line 2, which has the following \#include directive:

```
#include "Rectangle.h"
```

This directive includes the Rectangle.h file, which contains the Rectangle class declaration. Notice the name of the header file is enclosed in double-quote characters (" ") instead of angled brackets ( $<\gg$ ). When you are including a C++ system header file, such as iostream, you enclose the name of the file in angled brackets. This indicates the file is located in the compiler's include file directory. The include file directory is the directory or folder where all of the standard C++ header files are located. When you are including a header file that you have written, such as a class specification file, you enclose the name of the file in double-quote marks. This indicates the file is located in the current project directory.

Any file that uses the Rectang1e class must have an \#include directive for the Rectangle.h file. We need to include Rectangle.h in the class specification file because the functions in this file belong to the Rectangle class. Before the compiler can process a function with Rectangle: : in its name, it must have already processed the Rectangle class declaration.
Now that we have the Rectangle class stored in its own specification and implementation files, we can see how to use them in a program. Program 13-5 shows a modified version of Program 13-1. This version of the program does not contain the Rectangle class declaration, or the definitions of any of the class's member functions. Instead, it is designed to be compiled and linked with the class specification and implementation files. (This file can be found in the Student Source Code Folder Chapter 13\Rectangle Version 1.)

## Program 13-5

```
// This program uses the Rectangle class, which is declared in
// the Rectangle.h file. The member Rectangle class's member
// functions are defined in the Rectangle.cpp file. This program
// should be compiled with those files in a project.
#include <iostream>
#include "Rectangle.h" // Needed for Rectangle class
using namespace std;
int main()
{
    Rectangle box; // Define an instance of the Rectangle class
    double rectWidth; // Local variable for width
    double rectLength; // Local variable for length
    // Get the rectangle's width and length from the user.
    cout << "This program will calculate the area of a\n";
    cout << "rectangle. What is the width? ";
    cin >> rectWidth;
    cout << "What is the length? ";
    cin >> rectLength;
```

## Program 13-5 (continued)

23
24
25
26
27
28
29
30
31
32
33 }

```
```

```
22 // Store the width and length of the rectangle
```

```
22 // Store the width and length of the rectangle
```

// in the box object.

```
// in the box object.
box.setWidth(rectWidth);
box.setWidth(rectWidth);
box.setLength(rectLength);
box.setLength(rectLength);
// Display the rectangle's data.
// Display the rectangle's data.
cout << "Here is the rectangle's data:\n";
cout << "Here is the rectangle's data:\n";
cout << "Width: " << box.getWidth() << endl;
cout << "Width: " << box.getWidth() << endl;
cout << "Length: " << box.getLength() << endl;
cout << "Length: " << box.getLength() << endl;
cout << "Area: " << box.getArea() << endl;
cout << "Area: " << box.getArea() << endl;
return 0;
return 0;
}
```

Notice Program 13-5 has an \#include directive for the Rectangle.h file in line 6. This causes the declaration for the Rectangle class to be included in the file. To create an executable program from this file, the following steps must be taken:

- The implementation file, Rectangle.cpp, must be compiled. Rectangle.cpp is not a complete program, so you cannot create an executable file from it alone. Instead, you compile Rectangle.cpp to an object file that contains the compiled code for the Rectangle class. This file would typically be named Rectangle.obj.
- The main program file, Pr13-4.cpp, must be compiled. This file is not a complete program either because it does not contain any of the implementation code for the Rectangle class. So, you compile this file to an object file such as Pr13-4.obj.
- The object files, Pr13-4.obj and Rectangle.obj, are linked together to create an executable file, which would be named something like Pr13-4.exe.

This process is illustrated in Figure 13-15.
The exact details on how these steps take place are different for each C++ development system. Fortunately, most systems perform all of these steps automatically for you. For example, in Microsoft Visual Studio you create a project, then you simply add all of the files to the project. When you compile the project, the steps are taken care of for you and an executable file is generated.

Separating a class into a specification file and an implementation file provides a great deal of flexibility. First, if you wish to give your class to another programmer, you don't have to share all of your source code with that programmer. You can give him or her the specification file and the compiled object file for the class's implementation. The other programmer simply inserts the necessary \#include directive into his or her program, compiles it, and links it with your class's object file. This prevents the other programmer, who might not know all the details of your code, from making changes that will introduce bugs.

Separating a class into specification and implementation files also makes things easier when the class's member functions must be modified. It is only necessary to modify the implementation file and recompile it to a new object file. Programs that use the class don't have to be completely recompiled, just linked with the new object file.

Figure 13-15 Creating an executable file

### 13.6 Inline Member Functions

CONCEPT: When the body of a member function is written inside a class declaration, it is declared inline.

When the body of a member function is small, it is usually more convenient to place the function's definition, instead of its prototype, in the class declaration. For example, in the Rectangle class the member functions getWidth, getLength, and getArea each have only one statement. The Rectangle class could be revised as shown in the following listing. (This file can be found in the Student Source Code Folder Chapter 13\Rectangle Version 2.)

## Contents of Rectangle.h (Version 2)

```
// Specification file for the Rectangle class
// This version uses some inline member functions.
#ifndef RECTANGLE_H
#define RECTANGLE_H
class Rectangle
{
    private:
            double width;
            double length;
            public:
            void setWidth(doub1e);
            void setLength(double);
```

```
14
1 5 \text { doub1e getWidth() const}
1 6
1 7
18
19
20
21 double getArea() const
22 { return width * length; }
23 };
24 #endif
```

When a member function is defined in the declaration of a class, it is called an inline function. Notice because the function definitions are part of the class, there is no need to use the scope resolution operator and class name in the function header.
Notice the getWidth, getLength, and getArea functions are declared inline, but the setWidth and setLength functions are not. They are still defined outside the class declaration. The following listing shows the implementation file for the revised Rectangle class. (This file can be found in the Student Source Code Folder Chapter 13\Rectangle Version 2.)

## Contents of Rectang1e.cpp (Version 2)

```
// Implementation file for the Rectangle class.
// In this version of the class, the getWidth, getLength,
// and getArea functions are written inline in Rectangle.h.
#include "Rectangle.h" // Needed for the Rectangle class
#include <iostream> // Needed for cout
#include <cstdlib> // Needed for the exit function
using namespace std;
//*************************************************************
// setWidth sets the value of the member variable width.
//***************************************************************
void Rectangle::setWidth(double w)
{
    if (w >= 0)
        width = w;
        else
        {
            cout << "Invalid width\n";
            exit(EXIT_FAILURE);
    }
}
/|*************************************************************
// setLength sets the value of the member variable length.
//***************************************************************
```

27

```
void Rectang1e::setLength(double 1en)
{
    if (len >= 0)
        1ength = 1en;
    else
    {
        cout << "Invalid length\n";
        exit(EXIT_FAILURE);
    }
}
```

## Inline Functions and Performance

A lot goes on "behind the scenes" each time a function is called. A number of special items, such as the function's return address in the program and the values of arguments, are stored in a section of memory called the stack. In addition, local variables are created and a location is reserved for the function's return value. All this overhead, which sets the stage for a function call, takes precious CPU time. Although the time needed is minuscule, it can add up if a function is called many times, as in a loop.

Inline functions are compiled differently than other functions. In the executable code, inline functions aren't "called" in the conventional sense. In a process known as inline expansion, the compiler replaces the call to an inline function with the code of the function itself. This means the overhead needed for a conventional function call isn't necessary for an inline function and can result in improved performance.* Because the inline function's code can appear multiple times in the executable program, however, the size of the program can increase. ${ }^{\dagger}$

## Checkpoint

13.6 Why would you declare a class's member variables private?
13.7 When a class's member variables are declared private, how does code outside the class store values in, or retrieve values from, the member variables?
13.8 What is a class specification file? What is a class implementation file?
13.9 What is the purpose of an include guard?
13.10 Assume the following class components exist in a program:

BasePay class declaration
BasePay member function definitions
Overtime class declaration
Overtime member function definitions
In what files would you store each of these components?
13.11 What is an inline member function?

[^4]
### 13.7 Constructors

CONCEPT: A constructor is a member function that is automatically called when a class object is created.

A constructor is a member function that has the same name as the class. It is automatically called when the object is created in memory, or instantiated. It is helpful to think of constructors as initialization routines. They are very useful for initializing member variables or performing other setup operations.
To illustrate how constructors work, look at the following Demo class:

```
class Demo
{
pub1ic:
    Demo(); /l Constructor
};
Demo::Demo()
{
    cout << "Welcome to the constructor!\n";
}
```

The class Demo only has one member: a function also named Demo. This function is the constructor. When an instance of this class is defined, the function Demo is automatically called. This is illustrated in Program 13-6.

## Program 13-6

```
// This program demonstrates a constructor.
#include <iostream>
using namespace std;
// Demo class declaration.
class Demo
{
public:
    Demo(); // Constructor
};
Demo::Demo()
{
    cout << "Welcome to the constructor!\n";
}
//******************************************
// Function main.
//******************************************
```

21

```
int main()
{
    Demo demoObject; // Define a Demo object;
    cout << "This program demonstrates an object\n";
    cout << "with a constructor.\n";
    return 0;
}
```

## Program Output

Welcome to the constructor!
This program demonstrates an object
with a constructor.

Notice the constructor's function header looks different than that of a regular member function. There is no return type-not even void. This is because constructors are not executed by explicit function calls and cannot return a value. The function header of a constructor's external definition takes the following form:

ClassName: :ClassName(ParameterList)
In the general format, ClassName is the name of the class, and ParameterList is an optional list of parameter variable declarations.

In Program 13-6, demoObject's constructor executes automatically when the object is defined. Because the object is defined before the cout statements in function main, the constructor displays its message first. Suppose we had defined the Demo object between two cout statements, as shown here:

```
cout << "This is displayed before the object is created.\n";
Demo demoObject; // Define a Demo object.
cout << "\nThis is displayed after the object is created.\n";
```

This code would produce the following output:

```
This is displayed before the object is created.
Welcome to the constructor!
This is displayed after the object is created.
```

This simple Demo example illustrates when a constructor executes. More importantly, you should understand why a class should have a constructor. A constructor's purpose is to initialize an object's attributes. Because the constructor executes as soon as the object is created, it can initialize the object's data members to valid values before those members are used by other code. It is a good practice to always write a constructor for every class.
For example, the Rectangle class we looked at earlier could benefit from having a constructor. A program could define a Rectangle object then use that object to call the getArea function before any values were stored in width and length. Because the width and length member variables are not initialized, the function would return garbage. The following code shows a better version of the Rectangle class, equipped with a constructor. The constructor initializes both width and length to 0.0 . (These files can be found in the Student Source Code Folder Chapter 13\Rectangle Version 3.)

## Contents of Rectang1e.h (Version 3)

```
// Specification file for the Rectangle class
// This version has a constructor.
#ifndef RECTANGLE_H
#define RECTANGLE_H
class Rectangle
{
    private:
        double width;
        double length;
    public:
        Rectang1e(); // Constructor
        void setWidth(double);
        void setLength(double);
        double getWidth() const
        { return width; }
        double getLength() const
                { return length; }
        double getArea() const
        { return width * length; }
};
#endif
```

## Contents of Rectang1e.cpp (Version 3)

```
// Implementation file for the Rectangle class.
// This version has a constructor.
#include "Rectangle.h" // Needed for the Rectangle class
#include <iostream> // Needed for cout
#include <cstdlib> // Needed for the exit function
using namespace std;
/|*************************************************************
// The constructor initializes width and length to 0.0.
//**************************************************************
Rectangle::Rectangle()
{
    width = 0.0;
    1ength = 0.0;
}
//************************************************************
// setWidth sets the value of the member variable width.
//**************************************************************
void Rectangle::setWidth(double w)
{
    if (w >= 0)
            width = w;
```

```
        else
        {
        cout << "Invalid width\n";
        exit(EXIT_FAILURE);
        }
}
//************************************************************
// setLength sets the value of the member variable length. *
//************************************************************
void Rectang1e::setLength(double 1en)
{
    if (len >= 0)
            1ength = 1en;
        e1se
        {
            cout << "Invalid length\n";
            exit(EXIT_FAILURE);
        }
}
```

Program 13-7 demonstrates this new version of the class. It creates a Rectangle object then displays the values returned by the getWidth, getLength, and getArea member functions. (This file can be found in the Student Source Code Folder Chapter 13\Rectangle Version 3.)

## Program 13-7

```
// This program uses the Rectangle class's constructor.
#include <iostream>
#include "Rectangle.h" // Needed for Rectangle class
using namespace std;
int main()
{
    Rectangle box; // Define an instance of the Rectangle class
    // Display the rectangle's data.
    cout << "Here is the rectangle's data:\n";
    cout << "Width: " << box.getWidth() << endl;
    cout << "Length: " << box.getLength() << endl;
    cout << "Area: " << box.getArea() << endl;
    return O;
}
```

## Program Output

Here is the rectangle's data:
Width: 0
Length: 0
Area: 0

## Using Member Initialization Lists

The constructor in the previously shown Rectangle class uses assignment statements to store initial values in the width and length member variables, as shown here:

```
Rectangle::Rectang1e()
{
    width = 0.0;
    1ength = 0.0;
}
```

You can use an alternative technique, known as a member initialization list, to initialize the members of a class. Here is an example of the Rectangle class's constructor, rewritten to use a member initialization list instead of assignment statements:

```
Rectangle::Rectang1e() :
width(0.0), length(0.0)
{
}
```

In this version of the constructor, a colon appears at the end of the function header, followed by the member initialization list. The member initialization list shows each member variable's name, followed by an initial value enclosed in parentheses. The member variables are separated by commas in the list. This version of the constructor initializes the width and length member variables with the value 0.0 .

Notice in this version of the constructor, the constructor's body is empty. Because the initialization of the member variables is handled by the initialization list, there is nothing to do in the body of the constructor.

Many programmers prefer to use member initialization lists instead of assignment statements inside of the body of the constructor because, in some situations, it allows the compiler to generate more efficient code.

NOTE: When a constructor has a member initialization list, the initializations take place before any statements in the body of the constructor execute.

## In-Place Member Initialization

Prior to C++ 11, you could not initialize a member variable in its declaration statement. You had to use the class constructor to either assign initial values to the class's members or use a member initialization list in the constructor. In C++ 11, you can initialize a member variable in its declaration statement, just as you can with a regular variable. This is known as in-place initialization. Here is an example:

```
class Rectangle
{
private:
    double width = 0.0;
    double length = 0.0;
public:
    Public member functions appear here...
};
```

## The Default Constructor

All of the examples we have looked at in this section demonstrate default constructors. A default constructor is a constructor that takes no arguments. Like regular functions, constructors may accept arguments, have default arguments, be declared inline, and be overloaded. We will see examples of these as we progress through the chapter.
If you write a class with no constructor whatsoever, when the class is compiled, C++ will automatically write a default constructor that does nothing. For example, the first version of the Rectangle class had no constructor; so, when the class was compiled, C++ generated the following constructor:

```
Rectangle::Rectangle()
{ }
```

## Default Constructors and Dynamically Allocated Objects

Earlier we discussed how class objects may be dynamically allocated in memory. For example, assume the following pointer is defined in a program:

```
Rectangle *rectPtr = nullptr;
```

This statement defines rectPtr as a Rectangle pointer. It can hold the address of any Rectangle object. But because this statement does not actually create a Rectangle object, the constructor does not execute. Suppose we use the pointer in a statement that dynamically allocates a Rectangle object, as shown in the following code:

```
rectPtr = new Rectangle;
```

This statement creates a Rectangle object. When the Rectangle object is created by the new operator, its default constructor is automatically executed.

### 13.8 Passing Arguments to Constructors

CONCEPT: A constructor can have parameters and can accept arguments when an object is created.

Constructors may accept arguments in the same way as other functions. When a class has a constructor that accepts arguments, you can pass initialization values to the constructor when you create an object. For example, the following code shows yet another version of the Rectangle class. This version has a constructor that accepts arguments for the rectangle's width and length. (These files can be found in the Student Source Code Folder Chapter 13\Rectangle Version 4.)

Contents of Rectang1e.h (Version 4)

```
// Specification file for the Rectangle class
// This version has a constructor.
#ifndef RECTANGLE_H
#define RECTANGLE_H
class Rectang1e
```

```
{
    private:
            double width;
            double length;
            public:
            Rectangle(double, double); // Constructor
            void setWidth(double);
            void setLength(double);
            double getWidth() const
            { return width; }
            doub1e getLength() const
            { return length; }
            double getArea() const
            { return width * length; }
};
#endif
```

## Contents of Rectangle.cpp (Version 4)

```
// Implementation file for the Rectangle class.
// This version has a constructor that accepts arguments.
#include "Rectangle.h" // Needed for the Rectangle class
#include <iostream> // Needed for cout
#include <cstdlib> // Needed for the exit function
using namespace std;
/|*************************************************************
// The constructor accepts arguments for width and length.
//*************************************************************
Rectangle::Rectangle(double w, double len)
{
    width = w;
    length = 1en;
}
//**************************************************************
// setWidth sets the value of the member variable width.
//***************************************************************
void Rectangle::setWidth(double w)
{
    if (w >= 0)
            width = w;
    else
    {
            cout << "Invalid width\n";
            exit(EXIT_FAILURE);
        }
}
```

```
//***********************************************************
// setLength sets the value of the member variable length. *
|/|************************************************************
void Rectangle::setLength(double len)
{
    if (len >= 0)
        length = len;
    else
    {
        cout << "Invalid length\n";
        exit(EXIT_FAILURE);
    }
}
```

The constructor, which appears in lines 12 through 16 of Rectangle.cpp, accepts two arguments, which are passed into the w and 1 en parameters. The parameters are assigned to the width and length member variables. Because the constructor is automatically called when a Rectangle object is created, the arguments are passed to the constructor as part of the object definition. Here is an example:

Rectangle box(10.0, 12.0);
This statement defines box as an instance of the Rectangle class. The constructor is called with the value 10.0 passed into the $w$ parameter and 12.0 passed into the 1 en parameter. As a result, the object's width member variable will be assigned 10.0 and the length member variable will be assigned 12.0. This is illustrated in Figure 13-16.

Figure 13-16 Arguments passed to a constructor
The box object is initiali

| with width set to 10.0 |
| :--- |
| length set to 12.0 |

Rectangle box (10.0, 12.0) ; | width: 10.0 |
| ---: |
| length: 12.0 |

Program 13-8 demonstrates the class. (This file can be found in the Student Source Code Folder Chapter 13\Rectangle Version 4.)

## Program 13-8

1 // This program calls the Rectangle class constructor.
2 \#include <iostream>
3 \#include <iomanip>
4 \#include "Rectangle.h"
5 using namespace std;
6
(program continues)

```
Program 13-8 (continued)
int main()
{
    double houseWidth, // To hold the room width
            houseLength; // To hold the room length
    // Get the width of the house.
    cout << "In feet, how wide is your house? ";
    cin >> houseWidth;
    // Get the length of the house.
    cout << "In feet, how long is your house? ";
    cin >> houseLength;
    // Create a Rectangle object.
    Rectangle house(houseWidth, houseLength);
    // Display the house's width, length, and area.
    cout << setprecision(2) << fixed;
    cout << "The house is " << house.getWidth()
        << " feet wide.\n";
    cout << "The house is " << house.getLength()
        << " feet long.\n";
    cout << "The house is " << house.getArea()
        << " square feet in area.\n";
    return 0;
}
```

## Program Output with Example Input Shown in Bold

```
In feet, how wide is your house? 30 Enter
In feet, how long is your house? 60 Enter
The house is 30.00 feet wide.
The house is 60.00 feet long.
The house is 1800.00 square feet in area.
```

The statement in line 21 creates a Rectang1e object, passing the values in houseWidth and houseLength as arguments.

The following code shows another example: the Sale class. This class might be used in a retail environment where sales transactions take place. An object of the Sale class represents the sale of an item. (This file can be found in the Student Source Code Folder Chapter 13\Sale Version 1.)

## Contents of Sale.h (Version 1)

```
// Specification file for the Sale class.
#ifndef SALE_H
#define SALE_H
class Sale
```

```
{
private:
    double itemCost; // Cost of the item
    double taxRate; // Sales tax rate
public:
        Sale(double cost, double rate)
        { itemCost = cost;
                taxRate = rate; }
        double getItemCost() const
        { return itemCost; }
        double getTaxRate() const
        { return taxRate; }
        double getTax() const
            { return (itemCost * taxRate); }
        double getTotal() const
        { return (itemCost + getTax()); }
};
#endif
```

The itemCost member variable, declared in line 8, holds the selling price of the item. The taxRate member variable, declared in line 9, holds the sales tax rate. The constructor appears in lines 11 and 13. Notice the constructor is written inline. It accepts two arguments, the item cost and the sales tax rate. These arguments are used to initialize the itemCost and taxRate member variables. The getItemCost member function, in lines 15 and 16 , returns the value in itemCost, and the getTaxRate member function, in lines 18 and 19 , returns the value in taxRate. The getTax member function, in lines 21 and 22, calculates and returns the amount of sales tax for the purchase. The getTotal member function, in lines 24 and 25, calculates and returns the total of the sale. The total is the item cost plus the sales tax. Program 13-9 demonstrates the class. (This file can be found in the Student Source Code Folder Chapter 13lSale Version 1.)

## Program 13-9

```
// This program demonstrates passing an argument to a constructor.
#include <iostream>
#include <iomanip>
#include "Sale.h"
using namespace std;
int main()
{
    const double TAX_RATE = 0.06; // 6 percent sales tax rate
    double cost; // To hold the item cost
    // Get the cost of the item.
    cout << "Enter the cost of the item: ";
    cin >> cost;
```

```
Program 13-9 (continued)
1 5
16
1 7
18
19
20
21
22
```

```
24
25
26
27
    cout << itemSale.getTotal() << endl;
    return 0;
}
```

## Program Output with Example Input Shown in Bold

```
Enter the cost of the item: 10.00 Enter
```

The amount of sales tax is $\$ 0.60$
The total of the sale is $\$ 10.60$

In the example run of the program, the user enters 10.00 as the cost of the item. This value is stored in the local variable cost. In line 17 , the itemSale object is created. The values of the cost variable and the TAX_RATE constant are passed as arguments to the constructor. As a result, the object's cost member variable is initialized with the value 10.0 , and the rate member variable is initialized with the value 0.06 . This is illustrated in Figure 13-17.

Figure 13-17 Arguments passed to the constructor

The itemSa1e object is initialized with the cost member set to 10.0 and the rate member set to 0.06

```
cost: 10.0
rate: 0.06
```

## Using Default Arguments with Constructors

Like other functions, constructors may have default arguments. Recall from Chapter 6 that default arguments are passed to parameters automatically if no argument is provided in the function call. The default value is listed in the parameter list of the function's declaration or
the function header. The following code shows a modified version of the Sale class. This version's constructor uses a default argument for the tax rate. (This file can be found in the Student Source Code Folder Chapter 13\Sale Version 2.)

## Contents of Sale.h (Version 2)

```
// This version of the Sale class uses a default argument
// in the constructor.
#ifndef SALE_H
#define SALE_H
class Sale
{
private:
    double itemCost; // Cost of the item
    double taxRate; // Sales tax rate
public:
    Sale(double cost, double rate = 0.05)
        { itemCost = cost;
                taxRate = rate; }
    double getItemCost() const
        { return itemCost; }
    double getTaxRate() const
        { return taxRate; }
    double getTax() const
        { return (itemCost * taxRate); }
    double getTotal() const
        { return (itemCost + getTax()); }
};
#endif
```

If an object of this Sale class is defined with only one argument (for the cost parameter) passed to the constructor, the default argument 0.05 will be provided for the rate parameter. This is demonstrated in Program 13-10. (This file can be found in the Student Source Code Folder Chapter 13\Sale Version 2.)

## Program 13-10

```
// This program uses a constructor's default argument.
#include <iostream>
#include <iomanip>
#include "Sale.h"
using namespace std;
int main()
{
    double cost; // To hold the item cost
```

10

```
Program 13-10 (continued)
11 // Get the cost of the item.
12 cout << "Enter the cost of the item: ";
13 cin >> cost;
14
15
16
17
18
19
20
21
22
23
24
25
26
27
28
cout << itomSale getTotal()}<<<\mathrm{ endl;
return 0;
}
```

Program Output with Example Input Shown in Bold
Enter the cost of the item: 10.00 Enter
The amount of sales tax is $\$ 0.50$
The total of the sale is $\$ 10.50$

## More about the Default Constructor

It was mentioned earlier that when a constructor doesn't accept arguments, it is known as the default constructor. If a constructor has default arguments for all its parameters, it can be called with no explicit arguments. It then becomes the default constructor. For example, suppose the constructor for the Sale class had been written as the following:

```
Sale(double cost = 0.0, double rate = 0.05)
    { itemCost = cost;
        taxRate = rate; }
```

This constructor has default arguments for each of its parameters. As a result, the constructor can be called with no arguments, as shown here:

```
Sale itemSale;
```

This statement defines a Sale object. No arguments were passed to the constructor, so the default arguments for both parameters are used. Because this constructor can be called with no arguments, it is the default constructor.

## Classes with No Default Constructor

When all of a class's constructors require arguments, then the class does not have a default constructor. In such a case, you must pass the required arguments to the constructor when creating an object. Otherwise, a compiler error will result.

### 13.9 Destructors

CONCEPT: A destructor is a member function that is automatically called when an object is destroyed.

Destructors are member functions with the same name as the class, preceded by a tilde character ( $\sim$ ). For example, the destructor for the Rectangle class would be named $\sim$ Rectangle.

Destructors are automatically called when an object is destroyed. In the same way that constructors set things up when an object is created, destructors perform shutdown procedures when the object goes out of existence. For example, a common use of destructors is to free memory that was dynamically allocated by the class object.

Program 13-11 shows a simple class with a constructor and a destructor. It illustrates when, during the program's execution, each is called.

## Program 13-11

```
// This program demonstrates a destructor.
#include <iostream>
using namespace std;
class Demo
{
pub1ic:
        Demo(); // Constructor
        ~Demo(); // Destructor
};
Demo::Demo()
{
        cout << "Welcome to the constructor!\n";
}
Demo::~Demo()
{
    cout << "The destructor is now running.\n";
}
/|***********************************************
// Function main.
//***********************************************
int main()
{
        Demo demoObject; // Define a demo object;
        cout << "This program demonstrates an object\n";
        cout << "with a constructor and destructor.\n";
        return 0;
}
```

```
Program 13-11 (continued)
Program Output
Welcome to the constructor!
This program demonstrates an object
with a constructor and destructor.
The destructor is now running.
```

The following code shows a more realistic example of a class with a destructor. The ContactInfo class holds the following data about a contact:

- The contact's name
- The contact's phone number

The constructor accepts arguments for both items. The name and phone number are passed as a pointer to a C-string. Rather than storing the name and phone number in a char array with a fixed size, the constructor gets the length of the C-string and dynamically allocates just enough memory to hold it. The destructor frees the allocated memory when the object is destroyed. (This file can be found in the Student Source Code Folder Chapter 13\} ContactInfo Version 1.)

## Contents of ContactInfo.h (Version 1)

```
// Specification file for the Contact class.
#ifndef CONTACTINFO_H
#define CONTACTINFO_H
#include <cstring> // Needed for strlen and strcpy
// ContactInfo class declaration.
class ContactInfo
{
private:
    char *name; /l The name
    char *phone; // The phone number
public:
    // Constructor
    ContactInfo(char *n, char *p)
    { // Allocate just enough memory for the name and phone number.
        name = new char[strlen(n) + 1];
        phone = new char[strlen(p) + 1];
            // Copy the name and phone number to the allocated memory.
            strcpy(name, n);
            strcpy(phone, p); }
    // Destructor
    ~ContactInfo()
    { delete [] name;
        delete [] phone; }
    const char *getName() const
    { return name; }
```

```
    const char *getPhoneNumber() const
    { return phone; }
};
#endif
```

Notice the return type of the getName and getPhoneNumber functions in lines 28 through 32 is const char *. This means each function returns a pointer to a constant char. This is a security measure. It prevents any code that calls the functions from changing the string that the pointer points to.

Program 13-12 demonstrates the class. (This file can be found in the Student Source Code Folder Chapter 13\ContactInfo Version 1.)

## Program 13-12

```
// This program demonstrates a class with a destructor.
#include <iostream>
#include "ContactInfo.h"
using namespace std;
int main()
{
    // Define a ContactInfo object with the following data:
    // Name: Kristen Lee, Phone Number: 555-2021
    ContactInfo entry("Kristen Lee", "555-2021");
    // Display the object's data.
    cout << "Name: " << entry.getName() << endl;
    cout << "Phone Number: " << entry.getPhoneNumber() << endl;
    return 0;
}
```

## Program Output

Name: Kristen Lee
Phone Number: 555-2021

In addition to the fact that destructors are automatically called when an object is destroyed, the following points should be mentioned:

- Like constructors, destructors have no return type.
- Destructors cannot accept arguments, so they never have a parameter list.

## Destructors and Dynamically Allocated Class Objects

If a class object has been dynamically allocated by the new operator, its memory should be released when the object is no longer needed. For example, in the following code objectPtr is a pointer to a dynamically allocated ContactInfo class object:

```
// Define a ContactInfo pointer.
ContactInfo *objectPtr = nullptr;
// Dynamically create a ContactInfo object.
objectPtr = new ContactInfo("Kristen Lee", "555-2021");
```

The following statement shows the delete operator being used to destroy the dynamically created object:

```
delete objectPtr;
```

When the object pointed to by objectPtr is destroyed, its destructor is automatically called.

NOTE: If you have used a smart pointer such as unique_ptr (introduced in C++ 11) to allocate an object, the object will automatically be deleted, and its destructor will be called when the smart pointer goes out of scope. It is not necessary to use delete with a unique_ptr.

## Checkpoint

13.12 Briefly describe the purpose of a constructor.
13.13 Briefly describe the purpose of a destructor.
13.14 A member function that is never declared with a return data type, but that may have arguments is which of the following?
A) The constructor
B) The destructor
C) Both the constructor and the destructor
D) Neither the constructor nor the destructor
13.15 A member function that is never declared with a return data type and can never have arguments is which of the following?
A) The constructor
B) The destructor
C) Both the constructor and the destructor
D) Neither the constructor nor the destructor
13.16 Destructor function names always start with $\qquad$ .
A) A number
B) Tilde character ( $\sim$ )
C) A data type name
D) None of the above
13.17 A constructor that requires no arguments is called $\qquad$ .
A) A default constructor
B) An overloaded constructor
C) A null constructor
D) None of the above
13.18 True or False: Constructors are never declared with a return data type.
13.19 True or False: Destructors are never declared with a return type.
13.20 True or False: Destructors may take any number of arguments.

### 13.10 Overlloading Constructors

CONCEPT: A class can have more than one constructor.
Recall from Chapter 6 that when two or more functions share the same name, the function is said to be overloaded. Multiple functions with the same name may exist in a C++ program, as long as their parameter lists are different.
A class's member functions may be overloaded, including the constructor. One constructor might take an int argument, for example, while another constructor takes a double. There could even be a third constructor taking two integers. As long as each constructor takes a different list of parameters, the compiler can tell them apart. For example, the string class has several overloaded constructors. The following statement creates a string object with no arguments passed to the constructor:

```
string str;
```

This executes the string class's default constructor, which stores an empty string in the object. Another way to create a string object is to pass a string literal as an argument to the constructor, as shown here:

```
string str("Hello");
```

This executes an overloaded constructor, which stores the string "Hello" in the object.
Let's look at an example of how you can create overloaded constructors. The Inventory Item class holds the following data about an item that is stored in inventory:

- Item's description (a string object)
- Item's cost (a double)
- Number of units in inventory (an int)

The following code shows the class. To simplify the code, all the member functions are written inline. (This file can be found in the Student Source Code Folder Chapter 13\InventoryItem.)

## Contents of InventoryItem.h

```
// This class has overloaded constructors.
#ifndef INVENTORYITEM_H
#define INVENTORYITEM_H
#include <string>
using namespace std;
class InventoryItem
{
private:
    string description; // The item description
    double cost; // The item cost
    int units; // Number of units on hand
public:
    // Constructor #1 (default constructor)
    InventoryItem()
            { // Initialize description, cost, and units.
                description = "";
```

```
        cost = 0.0;
        units = 0; }
        // Constructor #2
        InventoryItem(string desc)
            { // Assign the value to description.
            description = desc;
            // Initialize cost and units.
            cost = 0.0;
            units = 0; }
    // Constructor #3
    InventoryItem(string desc, double c, int u)
        { // Assign values to description, cost, and units.
            description = desc;
            cost = c;
            units = u; }
    // Mutator functions
    void setDescription(string d)
        { description = d; }
        void setCost(double c)
        { cost = c; }
        void setUnits(int u)
            { units = u; }
    // Accessor functions
    string getDescription() const
        { return description; }
    doub1e getCost() const
        { return cost; }
    int getUnits() const
        { return units; }
};
#endif
```

The first constructor appears in lines 15 through 19. It takes no arguments, so it is the default constructor. It initializes the description variable to an empty string. The cost and units variables are initialized to 0 .

The second constructor appears in lines 22 through 28 . This constructor accepts only one argument, the item description. The cost and units variables are initialized to 0 .

The third constructor appears in lines 31 through 35 . This constructor accepts arguments for the description, cost, and units.

The mutator functions set values for description, cost, and units. Program 13-13 demonstrates the class. (This file can be found in the Student Source Code Folder Chapter 13\ InventoryItem.)

## Program 13-13

```
// This program demonstrates a class with overloaded constructors.
#include <iostream>
#include <iomanip>
#include "InventoryItem.h"
int main()
{
    // Create an InventoryItem object with constructor #1.
    InventoryItem item1;
    item1.setDescription("Hammer"); // Set the description
    item1.setCost(6.95); // Set the cost
    item1.setUnits(12); // Set the units
    // Create an InventoryItem object with constructor #2.
    InventoryItem item2("Pliers");
    // Create an InventoryItem object with constructor #3.
    InventoryItem item3("Wrench", 8.75, 20);
    cout << "The following items are in inventory:\n";
    cout << setprecision(2) << fixed << showpoint;
    // Display the data for item 1.
    cout << "Description: " << item1.getDescription() << endl;
    cout << "Cost: $" << item1.getCost() << endl;
    cout << "Units on Hand: " << item1.getUnits() << endl << endl;
    // Display the data for item 2.
    cout << "Description: " << item2.getDescription() << endl;
    cout << "Cost: $" << item2.getCost() << endl;
    cout << "Units on Hand: " << item2.getUnits() << endl << endl;
    // Display the data for item 3.
    cout << "Description: " << item3.getDescription() << endl;
    cout << "Cost: $" << item3.getCost() << endl;
    cout << "Units on Hand: " << item3.getUnits() << end1;
    return 0;
}
```

## Program Output

The following items are in inventory:
Description: Hammer
Cost: \$6.95
Units on Hand: 12
Description: Pliers
Cost: \$0.00
Units on Hand: 0
Description: Wrench
Cost: \$8.75
Units on Hand: 20

## 11

## Constructor Delegation

Often, a class will have multiple constructors that perform a similar set of steps, or some of the same steps. For example, look at the following Contact class:

```
class Contact
{
private:
    string name;
    string email;
    string phone;
public:
    // Constructor #1 (defau7t)
    Contact()
    { name = "";
        emai1 = "";
        phone = "";
    }
    // Constructor #2
    Contact(string n, string e, string p)
    { name = n;
        email = e;
        phone = p;
    }
    Other member functions follow...
};
```

In this class, both constructors perform a similar operation: They assign values to the name, emai1, and phone member variables. The default constructor assigns empty strings to the members, and the parameterized constructor assigns specified values to the members.
In C++ 11, it is possible for one constructor to call another constructor in the same class. This is known as constructor delegation. The following code shows how we can use constructor delegation in the Contact class:

```
class Contact
{
private:
    string name;
    string email;
    string phone;
public:
    // Constructor #1 (defau7t)
    Contact() : Contact("", "", "")
    { }
    // Constructor #2
    Contact(string n, string e, string p)
    { name = n;
        email = e;
        phone = p;
    }
```

    Other member functions follow...
    \};

In this version of the class, the default constructor calls constructor \#2. Notice that a colon appears at the end of the default constructor's header, followed by a call to constructor \#2 with three empty strings listed inside the parentheses. Any time the Contact class's default constructor is called, it calls constructor \#2, passing the empty strings as arguments. As a result, the empty strings are assigned to the object's name, emai1, and phone member variables.

## Only One Default Constructor and One Destructor

When an object is defined without an argument list for its constructor, the compiler automatically calls the default constructor. For this reason, a class may have only one default constructor. If there were more than one constructor that could be called without an argument, the compiler would not know which one to call by default.
Remember, a constructor whose parameters all have a default argument is considered a default constructor. It would be an error to create a constructor that accepts no parameters along with another constructor that has default arguments for all its parameters. In such a case, the compiler would not be able to resolve which constructor to execute.

Classes may also only have one destructor. Because destructors take no arguments, the compiler has no way to distinguish different destructors.

## Other Overloaded Member Functions

Member functions other than constructors can also be overloaded. This can be useful because sometimes you need several different ways to perform the same operation. For example, in the InventoryItem class we could have overloaded the setCost function as shown here:

```
void setCost(double c)
    { cost = c; }
void setCost(string c)
    { cost = stod(c); }
```

The first version of the function accepts a double argument and assigns it to cost. The second version of the function accepts a string object. This could be used where you have the cost of the item stored in a string object. The function calls the stod function to convert the string to a double and assigns its value to cost.

### 13.11 Private Member Functions

CONCEPT: A private member function may only be called from a function that is a member of the same class.

Sometimes a class will contain one or more member functions that are necessary for internal processing, but should not be called by code outside the class. For example, a class might have a member function that performs a calculation only when a value is stored in a particular member variable and should not be performed at any other time. That function should not be directly accessible by code outside the class because it might get called at the wrong time. In this case, the member function should be declared private. When a member function is declared private, it may only be called internally.

For example, consider the following version of the Contact Info class. (This file can be found in the Student Source Code Folder Chapter 13\ContactInfo Version 2.)

## Contents of ContactInfo.h (Version 2)

```
// Contact class specification file (version 2)
#ifndef CONTACTINFO_H
#define CONTACTINFO_H
#include <cstring> // Needed for strlen and strcpy
// ContactInfo class declaration.
class ContactInfo
{
private:
    char *name; // The contact's name
    char *phone; // The contact's phone number
    // Private member function: initName
    // This function initializes the name attribute.
    void initName(char *n)
    { name = new char[strlen(n) + 1];
        strcpy(name, n); }
    // Private member function: initPhone
    // This function initializes the phone attribute.
    void initPhone(char *p)
    { phone = new char[strlen(p) + 1];
        strcpy(phone, p); }
public:
    // Constructor
    ContactInfo(char *n, char *p)
    { // Initialize the name attribute.
        initName(n);
        // Initialize the phone attribute.
        initPhone(n); }
    // Destructor
    ~ContactInfo()
    { delete [] name;
        delete [] phone; }
    const char *getName() const
    { return name; }
    const char *getPhoneNumber() const
    { return phone; }
};
#endif
```

In this version of the class, the logic in the constructor is modularized. It calls two private member functions: initName and initPhone. The initName function allocates memory for the name attribute and initializes it with the value pointed to by the n parameter. The
initPhone function allocates memory for the phone attribute and initializes it with the value pointed to by the p parameter. These functions are private because they should be called only from the constructor. If they were ever called by code outside the class, they would change the values of the name and phone pointers without deallocating the memory that they currently point to.

### 13.12 Arrays of Objects

CONCEPT: You may define and work with arrays of class objects.
As with any other data type in C++, you can define arrays of class objects. An array of InventoryItem objects could be created to represent a business's inventory records. Here is an example of such a definition:

```
const int ARRAY_SIZE = 40;
InventoryItem inventory[ARRAY_SIZE];
```

This statement defines an array of 40 InventoryItem objects. The name of the array is inventory, and the default constructor is called for each object in the array.

If you wish to define an array of objects and call a constructor that requires arguments, you must specify the arguments for each object individually in an initializer list. Here is an example:

```
InventoryItem inventory[] = {"Hammer", "Wrench", "P1iers"};
```

The compiler treats each item in the initializer list as an argument for an array element's constructor. Recall that the second constructor in the InventoryItem class declaration takes the item description as an argument. So, this statement defines an array of three objects and calls that constructor for each object. The constructor for inventory [0] is called with "Hammer" as its argument, the constructor for inventory [1] is called with "Wrench" as its argument, and the constructor for inventory [2] is called with "Pliers" as its argument.

WARNING! If the class does not have a default constructor you must provide an initializer for each object in the array.

If a constructor requires more than one argument, the initializer must take the form of a function call. For example, look at the following definition statement:

```
InventoryItem inventory[] = { InventoryItem("Hammer", 6.95, 12),
    InventoryItem("Wrench", 8.75, 20),
    InventoryItem("Pliers", 3.75, 10) };
```

This statement calls the third constructor in the InventoryItem class declaration for each object in the inventory array.

It isn't necessary to call the same constructor for each object in an array. For example, look at the following statement:

```
InventoryItem inventory[] = { "Hammer",
    InventoryItem("Wrench", 8.75, 20),
    "Pliers" };
```

This statement calls the second constructor for inventory[0] and inventory[2], and calls the third constructor for inventory [1].

If you do not provide an initializer for all of the objects in an array, the default constructor will be called for each object that does not have an initializer. For example, the following statement defines an array of three objects, but only provides initializers for the first two. The default constructor is called for the third object.

```
const int SIZE = 3;
InventoryItem inventory [SIZE] = { "Hammer",
    InventoryItem("Wrench", 8.75, 20) };
```

In summary, if you use an initializer list for class object arrays, there are three things to remember:

- If there is no default constructor you must furnish an initializer for each object in the array.
- If there are fewer initializers in the list than objects in the array, the default constructor will be called for all the remaining objects.
- If a constructor requires more than one argument, the initializer takes the form of a constructor function call.

## Accessing Members of Objects in an Array

Objects in an array are accessed with subscripts, just like any other data type in an array. For example, to call the setUnits member function of inventory[2], the following statement could be used:

```
inventory[2].setUnits(30);
```

This statement sets the units variable of inventory[2] to the value 30. Program 13-14 shows an array of InventoryItem objects being used in a complete program. (This file is stored in the Student Source Code Folder Chapter 13\InventoryItem.)

## Program 13-14

```
// This program demonstrates an array of class objects.
#include <iostream>
#include <iomanip>
#include "InventoryItem.h"
using namespace std;
int main()
{
    const int NUM_ITEMS = 5;
    InventoryItem inventory[NUM_ITEMS] = {
                InventoryItem("Hammer", 6.95, 12),
                                InventoryItem("Wrench", 8.75, 20),
                                InventoryItem("Pliers", 3.75, 10),
                                InventoryItem("Ratchet", 7.95, 14),
                                InventoryItem("Screwdriver", 2.50, 22) };
```

```
    cout << setw(14) <<"Inventory Item"
        << setw(8) << "Cost" << setw(8)
        << setw(16) << "Units on Hand\n";
    cout << "-------------------------------------\n";
    for (int i = 0; i < NUM_ITEMS; j++)
    {
        cout << setw(14) << inventory[i].getDescription();
        cout << setw(8) << inventory[i].getCost();
        cout << setw(7) << inventory[i].getUnits() << endl;
    }
    return 0;
}
```

## Program Output

## Inventory Item Cost Units on Hand

| Hammer | 6.95 | 12 |
| :---: | :---: | :---: |
| Wrench | 8.75 | 20 |
| Pliers | 3.75 | 10 |
| Ratchet | 7.95 | 14 |
| Screwdriver | 2.5 | 22 |

## Checkpoint

13.21 What will the following program display on the screen?

```
#include <iostream>
using namespace std;
class Tank
{
private:
    int gallons;
public:
    Tank()
        { gallons = 50; }
    Tank(int gal)
        { gallons = gal; }
    int getGallons()
        { return gallons; }
    };
int main()
{
    Tank storage[3] = { 10, 20 };
    for (int index = 0; index < 3; index++)
        cout << storage[index].getGallons() << endl;
        return 0;
}
```

13.22 What will the following program display on the screen?

```
#include <iostream>
using namespace std;
class Package
{
private:
    int value;
public:
    Package()
        { value = 7; cout << value << endl; }
        Package(int v)
            { value = v; cout << value << endl; }
    ~Package()
            { cout << value << endl; }
};
int main()
{
    Package obj1(4);
    Package obj2;
    Package obj3(2);
        return 0;
}
```

13.23 In your answer for Checkpoint 13.22, indicate for each line of output whether the line is displayed by constructor \#1, constructor \#2, or the destructor.
13.24 Why would a member function be declared private?
13.25 Define an array of three InventoryItem objects.
13.26 Complete the following program so it defines an array of Yard objects. The program should use a loop to ask the user for the length and width of each Yard.

```
#include <iostream>
using namespace std;
class Yard
{
private:
    int length, width;
public:
    Yard()
            { length = 0; width = 0; }
        setLength(int len)
            { length = len; }
        setWidth(int w)
            { width = w; }
};
int main()
{
    // Finish this program
}
```

### 13.13 Focus on Problem Solving and Program Design: An OOP Case Study

You are a programmer for the Home Software Company. You have been assigned to develop a class that models the basic workings of a bank account. The class should perform the following tasks:

- Save the account balance.
- Save the number of transactions performed on the account.
- Allow deposits to be made to the account.
- Allow withdrawals to be taken from the account.
- Calculate interest for the period.
- Report the current account balance at any time.
- Report the current number of transactions at any time.

## Private Member Variables

Table 13-4 lists the private member variables needed by the class.

Table 13-4 Private Member Variables

| Variable | Description |
| :--- | :--- |
| balance | A double that holds the current account balance. |
| interestRate | A double that holds the interest rate for the period. |
| interest | A double that holds the interest earned for the current period. |
| transactions | An integer that holds the current number of transactions. |

## Public Member Functions

Table 13-5 lists the public member functions needed by the class.

Table 13-5 Public Member Functions

| Function | Description |
| :--- | :--- |
| Constructor | Takes arguments to be initially stored in the balance and interestRate <br> members. The default value for the balance is zero, and the default value <br> for the interest rate is 0.045. |
| setInterestRate | Takes a double argument, which is stored in the interestRate member. <br> makeDeposit |
| Takes a double argument, which is the amount of the deposit. This argu- <br> ment is added to balance. |  |
| withdraw | Takes a double argument, which is the amount of the withdrawal. This <br> value is subtracted from the balance, unless the withdrawal amount is <br> greater than the balance. If this happens, the function reports an error. |

Table 13-5 (continued)

| Function | Description |
| :--- | :--- |
| calcInterest | Takes no arguments. This function calculates the amount of interest for <br> the current period, stores this value in the interest member, then adds <br> it to the balance member. |
| getInterestRate | Returns the current interest rate (stored in the interestRate member). <br> getBalance <br> getInterest |
| Returns the current balance (stored in the balance member). <br> Returns the interest earned for the current period (stored in the <br> interest member). |  |
| getTransactions | Returns the number of transactions for the current period (stored in the <br> transactions member). |

## The Class Declaration

The following listing shows the class declaration:

## Contents of Account.h

```
// Specification file for the Account class.
#ifndef ACCOUNT_H
#define ACCOUNT_H
class Account
{
private:
    double balance; // Account balance
    double interestRate; // Interest rate for the period
    double interest; // Interest earned for the period
    int transactions; // Number of transactions
public:
    Account(double iRate = 0.045, double bal = 0)
        { balance = bal;
            interestRate = iRate;
            interest = 0;
            transactions = 0; }
    void setInterestRate(double iRate)
        { interestRate = iRate; }
    void makeDeposit(double amount)
        { balance += amount; transactions++; }
    void withdraw(double amount); // Defined in Account.cpp
    void calcInterest()
        { interest = balance * interestRate; balance += interest; }
    double getInterestRate() const
        { return interestRate; }
```

```
    double getBalance() const
    { return balance; }
        double getInterest() const
        { return interest; }
        int getTransactions() const
        { return transactions; }
};
#endif
```

## The withdraw Member Function

The only member function not written inline in the class declaration is withdraw. The purpose of that function is to subtract the amount of a withdrawal from the balance member. If the amount to be withdrawn is greater than the current balance, however, no withdrawal is made. The function returns true if the withdrawal is made, or false if there is not enough in the account.

## Contents of Account.cpp

```
// Implementation file for the Account class.
#include "Account.h"
bool Account::withdraw(double amount)
{
    if (balance < amount)
        return false; // Not enough in the account
    else
    {
        balance -= amount;
        transactions++;
        return true;
    }
}
```

## The Class's Interface

The balance, interestRate, interest, and transactions member variables are private, so they are hidden from the world outside the class. The reason is that a programmer with direct access to these variables might unknowingly commit any of the following errors:

- A deposit or withdrawal might be made without the transactions member being incremented.
- A withdrawal might be made for more than is in the account. This will cause the balance member to have a negative value.
- The interest rate might be calculated and the balance member adjusted, but the amount of interest might not get recorded in the interest member.
- The wrong interest rate might be used.

Because of the potential for these errors, the class contains public member functions that ensure the proper steps are taken when the account is manipulated.

## Implementing the Class

Program 13-15 shows an implementation of the Account class. It presents a menu for displaying a savings account's balance, number of transactions, and interest earned. It also allows the user to deposit an amount into the account, make a withdrawal from the account, and calculate the interest earned for the current period.

## Program 13-15

```
    // This program demonstrates the Account class.
    #include <iostream>
    #include <cctype>
    #include <iomanip>
    #include "Account.h"
    using namespace std;
    // Function prototypes
void displayMenu();
void makeDeposit(Account &);
void withdraw(Account &);
    int main()
{
            Account savings; // Savings account object
            char choice; // Menu selection
            // Set numeric output formatting.
            cout << fixed << showpoint << setprecision(2);
            do
            {
                // Display the menu and get a valid selection.
                    displayMenu();
                cin >> choice;
                while (toupper(choice) < 'A' || toupper(choice) > 'G')
                {
                    cout << "Please make a choice in the range "
                    << "of A through G:";
                    cin >> choice;
                }
                    // Process the user's menu selection.
                switch(choice)
                {
                case 'a':
                    case 'A': cout << "The current balance is $";
                    cout << savings.getBalance() << endl;
                break;
            case 'b':
            case 'B': cout << "There have been ";
                    cout << savings.getTransactions()
                    << " transactions.\n";
```

```
                    break;
            case 'c':
            case 'C': cout << "Interest earned for this period: $";
                    cout << savings.getInterest() << endl;
                    break;
            case 'd':
            case 'D': makeDeposit(savings);
                    break;
            case 'e':
            case 'E': withdraw(savings);
                break;
            case 'f':
            case 'F': savings.calcInterest();
            cout << "Interest added.\n";
        }
    } while (toupper(choice) != 'G');
    return 0;
}
|/**********************************************************

### 13.14 Focus on Object-Oriented Programming: Simulating Dice with Objects

Dice traditionally have six sides, representing the values 1 to 6 . Some games, however, use specialized dice that have a different number of sides. For example, the fantasy role-playing game Dungeons and Dragons ${ }^{\circledR}$ uses dice with four, six, eight, ten, twelve, and twenty sides.
Suppose you are writing a program that needs to roll simulated dice with various numbers of sides. A simple approach would be to write a Die class with a constructor that accepts the number of sides as an argument. The class would also have appropriate methods for rolling the die and getting the die's value. An example of such a class follows. (These files can be found in the Student Source Code Folder Chapter 13\Dice.)

## Contents of Die.h

```
// Specification file for the Die class
#ifndef DIE_H
#define DIE_H
class Die
{
private:
    int sides; /l Number of sides
    int value; // The die's value
pub1ic:
            Die(int = 6); // Constructor
    void roll(); // Rolls the die
    int getSides(); /l Returns the number of sides
    int getValue(); // Returns the die's value
};
#endif
```

## Contents of Die.cpp

```
// Implememtation file for the Die class
#include <cstdlib> // For rand and srand
#include <ctime> // For the time function
```

```
#include "Die.h"
using namespace std;
/|********************************************************
// The constructor accepts an argument for the number
// of sides for the die, and performs a roll.
//*********************
{
    // Get the system time.
    unsigned seed = time(0);
    // Seed the random number generator.
    srand(seed);
    // Set the number of sides.
    sides = numSides;
    // Perform an initial roll.
    rol1();
}
/|********************************************************
// The roll member function simulates the rolling of *
// the die.
//*********************************************************
void Die::roll()
{
    // Constant for the minimum die value
    const int MIN_VALUE = 1; // Minimum die value
    // Get a random value for the die.
    value = (rand() % (sides - MIN_VALUE + 1)) + MIN_VALUE;
}
//********************************************************
// The getSides member function returns the number of *
// for this die.
//********************************************************
int Die::getSides()
{
    return sides;
}
/|*********************************************************
// The getValue member function returns the die's value.*
//***********************************************************
int Die::getValue()
{
    return value;
}
```

Here is a synopsis of the class members:

#### Abstract

sides Declared in line 8 of Die.h. This is an int member variable that will hold the number of sides for the die. value Declared in line 9 of Die.h. This is an int member variable that will hold the die's value once it has been rolled. Constructor The constructor (lines 11 through 24 in Die.cpp) has a parameter for the number of sides. Notice in the constructor's prototype (line 12 in Die.h) that the parameter's default value is 6 . When the constructor executes, line 14 gets the system time and line 17 uses that value to seed the random number generator. Line 20 assigns the constructor's parameter to the sides member variable, and line 23 calls the roll member function, which simulates the rolling of the die. roll The roll member function (lines 30 through 37 in Die.cpp) simulates the rolling of the die. The MIn_VALUE constant, defined in line 33, is the minimum value for the die. Line 36 generates a random number within the appropriate range for this particular die and assigns it to the value member variable. getSides The getSides member function (lines 43 through 46) returns the sides member variable. getValue The getValue member function (lines 51 through 54 ) returns the value member variable.

The code in Program 13-16 demonstrates the class. It creates two instances of the Die class: one with six sides, and the other with twelve sides. It then simulates five rolls of the dice.

## Program 13-16

```
// This program simulates the rolling of dice.
#include <iostream>
#include "Die.h"
using namespace std;
int main()
{
    const int DIE1_SIDES = 6; // Number of sides for die #1
    const int DIE2_SIDES = 12; // Number of sides for die #2
    const int MAX_ROLLS = 5; // Number of times to roll
    // Create two instances of the Die class.
    Die die1(DIE1_SIDES);
    Die die2(DIE2_SIDES);
    // Display the initial state of the dice.
    cout << "This simulates the rolling of a "
        << die1.getSides() << " sided die and a "
        << die2.getSides() << " sided die.\n";
```

```
21
22
23
24
25
26
27
28
29
30
31
32
33
34
35
36
37
38
39 }
```

## Program Output

This simulates the rolling of a 6 sided die and a 12 sided die. Initial value of the dice:

17
Rolling the dice 5 times.
62
35
42
511
47

Let's take a closer look at the program:

Lines 8 to 10: | These statements declare three constants. DIE1_SIDES is the |
| :--- |
| number of sides for the first die (6), DIE2_SIDES is the number |
| of sides for the second die (12), and MAX_ROLLS is the number |
| of times to roll the die (5). |

Lines 13 to 14: | These statements create two instances of the Die class. Notice |
| :--- |
| DIE1_SIDES, which is 6 , is passed to the constructor in line 13, |
| and DIE2_SIDES, which is 12, is passed to the constructor in line |
| 14. As a result, die1 will reference a Die object with six sides, and |
| die2 will reference a Die object with twelve sides. |

Lines 22 to 23: $\quad$| This statement displays the initial value of both Die objects. |
| :--- |
| (Recall that the Die class constructor performs an initial roll of |
| the die.) |

Lines 28 to 37: | This for loop iterates five times. Each time the loop iterates, |
| :--- |
| line 31 calls the die1 object's roll method, and line 32 calls the |
| die2 object's roll method. Lines 35 and 36 display the values |
| of both dice. |

### 13.15 Focus on Object-Oriented Design: The Unified Modeling Language (UML)

CONCEPT: The Unified Modeling Language provides a standard method for graphically depicting an object-oriented system.

When designing a class, it is often helpful to draw a UML diagram. UML stands for Unified Modeling Language. The UML provides a set of standard diagrams for graphically depicting object-oriented systems. Figure 13-18 shows the general layout of a UML diagram for a class. Notice the diagram is a box that is divided into three sections. The top section is where you write the name of the class. The middle section holds a list of the class's member variables. The bottom section holds a list of the class's member functions.

Figure 13-18 General layout of a UML diagram

Earlier in this chapter, you studied a Rectangle class that could be used in a program that works with rectangles. The first version of the Rectangle class that you studied had the following member variables:

- width
- length

The class also had the following member functions:

- setWidth
- setLength
- getWidth
- getLength
- getArea

From this information alone we can construct a simple UML diagram for the class, as shown in Figure 13-19.

Figure 13-19 Rectangle class

| Rectangle |
| :--- |
| width |
| length |
| setWidth() |
| setLength() |
| getWidth() |
| getLength() |
| getArea() |

The UML diagram in Figure 13-19 tells us the name of the class, the names of the member variables, and the names of the member functions. The UML diagram in Figure 13-19 does not convey many of the class details, however, such as access specification, member variable data types, parameter data types, and function return types. The UML provides optional notation for these types of details.

## Showing Access Specification in UML Diagrams

The UML diagram in Figure 13-19 lists all of the members of the Rectangle class, but does not indicate which members are private and which are public. In a UML diagram you may optionally place a - character before a member name to indicate that it is private, or a + character to indicate that it is public. Figure 13-20 shows the UML diagram modified to include this notation.

## Figure 13-20 Rectangle class with access specification

| Rectangle |
| :---: |
| - width <br> - length |
| + setWidth() <br> + setLength() <br> + getWidth() <br> + getLength() <br> + getArea() |

## Data Type and Parameter Notation in UML Diagrams

The Unified Modeling Language also provides notation that you may use to indicate the data types of member variables, member functions, and parameters. To indicate the data type of a member variable, place a colon followed by the name of the data type after the name of the variable. For example, the width variable in the Rectangle class is a double. It could be listed as follows in the UML diagram:

- width : double

NOTE: In UML notation the variable name is listed first, then the data type. This is the opposite of C++ syntax, which requires the data type to appear first.

The return type of a member function can be listed in the same manner: After the function's name, place a colon followed by the return type. The Rectangle class's getLength function returns a double, so it could be listed as follows in the UML diagram:

```
+ getLength() : double
```

Parameter variables and their data types may be listed inside a member function's parentheses. For example, the Rectangle class's setLength function has a double parameter named len, so it could be listed as follows in the UML diagram:

```
+ setLength(len : double) : void
```

Figure 13-21 shows a UML diagram for the Rectang1e class with parameter and data type notation.

Figure 13-21 Rectangle class with access specification and return types

| Rectangle |
| :--- |
| - width : double |
| - length : double |
| + setWidth(w : double) : void |
| + setLength(1en : double) : void |
| + getWidth() : double |
| + getLength() : double |
| + getArea() $:$ double |

## Showing Constructors and Destructors in a UML Diagram

There is more than one accepted way of showing a class constructor in a UML diagram. In this book, we will show a constructor just as any other function, except we will list no return type. For example, Figure 13-22 shows a UML diagram for the InventoryItem class we looked at previously in this chapter.

Figure 13-22 InventoryItem class

|  | InventoryItem |
| :--- | :--- |
| - description : string |  |
| - cost : double |  |
| - units : int |  |
| + InventoryItem() : |  |
| + InventoryItem(desc : string) : |  |
| + InventoryItem(desc : string, |  |
| c : double, u : int) |  |
| + setDescription(d : string) : void |  |
| + setCost(c : double) : void |  |
| + setUnits(u: int) : void |  |
| + getDescription() : string |  |
| + getCost() : double |  |
| + getUnits() : int |  |

13.16 Focus on Object-Oriented Design: Finding the Classes and Their Responsibilities

CONCEPT: One of the first steps in creating an object-oriented application is determining the classes that are necessary and their responsibilities within the application.

So far, you have learned the basics of writing a class, creating an object from the class, and using the object to perform operations. This knowledge is necessary to create an
object-oriented application, but it is not the first step in designing the application. The first step is to analyze the problem you are trying to solve and determine the classes you will need. In this section, we will discuss a simple technique for finding the classes in a problem and determining their responsibilities.

## Finding the Classes

When developing an object-oriented application, one of your first tasks is to identify the classes you will need to create. Typically, your goal is to identify the different types of realworld objects that are present in the problem, then create classes for those types of objects within your application.

Over the years, software professionals have developed numerous techniques for finding the classes in a given problem. One simple and popular technique involves the following steps:

1. Get a written description of the problem domain.
2. Identify all the nouns (including pronouns and noun phrases) in the description. Each of these is a potential class.
3. Refine the list to include only the classes that are relevant to the problem.

Let's take a closer look at each of these steps.

## Write a Description of the Problem Domain

The problem domain is the set of real-world objects, parties, and major events related to the problem. If you adequately understand the nature of the problem you are trying to solve, you can write a description of the problem domain yourself. If you do not thoroughly understand the nature of the problem, you should have an expert write the description for you.

For example, suppose we are programming an application that the manager of Joe's Automotive Shop will use to print service quotes for customers. Here is a description that an expert, perhaps Joe himself, might have written:

Joe's Automotive Shop services foreign cars, and specializes in servicing cars made by Mercedes, Porsche, and BMW. When a customer brings a car to the shop, the manager gets the customer's name, address, and telephone number. The manager then determines the make, model, and year of the car and gives the customer a service quote. The service quote shows the estimated parts charges, estimated labor charges, sales tax, and total estimated charges.
The problem domain description should include any of the following:

- Physical objects such as vehicles, machines, or products
- Any role played by a person, such as manager, employee, customer, teacher, student, and so on.
- The results of a business event, such as a customer order, or in this case, a service quote
- Recordkeeping items, such as customer histories and payroll records

## Identify All of the Nouns

The next step is to identify all of the nouns and noun phrases. (If the description contains pronouns, include them as well.) Here's another look at the previous problem domain description. This time, the nouns and noun phrases appear in bold.

Joe's Automotive Shop services foreign cars, and specializes in servicing cars made by Mercedes, Porsche, and BMW. When a customer brings a car to the shop, the manager gets the customer's name, address, and telephone number. The manager then determines the make, model, and year of the car, and gives the customer a service quote. The service quote shows the estimated parts charges, estimated labor charges, sales tax, and total estimated charges.

Notice some of the nouns are repeated. The following list shows all of the nouns without duplicating any of them:

```
address
BMW
car
cars
customer
estimated labor charges
estimated parts charges
foreign cars
Joe's Automotive Shop
make
manager
Mercedes
model
name
Porsche
sales tax
service quote
shop
telephone number
total estimated charges
year
```

## Refine the List of Nouns

The nouns that appear in the problem description are merely candidates to become classes. It might not be necessary to make classes for them all. The next step is to refine the list to include only the classes that are necessary to solve the particular problem at hand. We will look at the common reasons that a noun can be eliminated from the list of potential classes.

1. Some of the nouns really mean the same thing.

In this example, the following sets of nouns refer to the same thing:

- cars and foreign cars

These both refer to the general concept of a car.

- Joe's Automotive Shop and shop

Both of these refer to the company "Joe's Automotive Shop."

We can settle on a single class for each of these. In this example we will arbitrarily eliminate foreign cars from the list, and use the word cars. Likewise, we will eliminate Joe's Automotive Shop from the list and use the word shop. The updated list of potential classes is:

```
address
BMW
car
cars
customer
estimated labor charges
estimated parts charges
foreign ears
Joe's Automotive Shop
make
manager
```

Because cars and foreign cars mean the same thing in this problem, we have eliminated foreign cars. Also, because Joe's Automotive Shop and shop mean the same thing, we have eliminated Joe's Automotive Shop.

```
Mercedes
model
name
Porsche
sales tax
service quote
shop
telephone number
total estimated charges
year
```

2. Some nouns might represent items we do not need to be concerned with in order to solve the problem.

A quick review of the problem description reminds us of what our application should do: print a service quote. In this example, we can eliminate two unnecessary classes from the list:

- We can cross shop off the list because our application only needs to be concerned with individual service quotes. It doesn't need to work with or determine any companywide information. If the problem description asked us to keep a total of all the service quotes, then it would make sense to have a class for the shop.
- We will not need a class for the manager because the problem statement does not direct us to process any information about the manager. If there were multiple shop managers, and the problem description had asked us to record which manager generated each service quote, then it would make sense to have a class for the manager.

The updated list of potential classes at this point is:

```
address
BMW
car
cars
customer
estimated labor charges
estimated parts charges
foreign ears
Joe's Automotive Shop
make
manager
Mercedes
model
name
Porsche
sales tax
service quote
shop
telephone number
total estimated charges
year
```

Our problem description does not direct us to process any information about the shop, or any information about the manager, so we have eliminated those from the list.

## 3. Some of the nouns might represent objects, not classes.

We can eliminate Mercedes, Porsche, and BMW as classes because, in this example, they all represent specific cars and can be considered instances of a cars class. Also, we can eliminate the word car from the list. In the description, it refers to a specific car brought to the shop by a customer. Therefore, it would also represent an instance of a cars class. At this point the updated list of potential classes is:

```
address
BMW
ear
cars
customer
estimated labor charges
estimated parts charges
foreign cars
Joe's Automotive Shop
manager
make
Mereedes
model
name
Porsehe
sales tax
service quote
shop
telephone number
total estimated charges
year
```

We have eliminated Mercedes, Porsche, BMW, and car because they are all instances of a cars class. That means these nouns identify objects, not classes.

NOTE: Some object-oriented designers take note of whether a noun is plural or singular. Sometimes a plural noun will indicate a class, and a singular noun will indicate an object.
4. Some of the nouns might represent simple values that can be stored in a variable, and do not require a class.
Remember, a class contains attributes and member functions. Attributes are related items that are stored within an object of the class, and define the object's state. Member functions are actions or behaviors that may be performed by an object of the class. If a noun represents a type of item that would not have any identifiable attributes or member functions, then it can probably be eliminated from the list. To help determine whether a noun represents an item that would have attributes and member functions, ask the following questions about it:

- Would you use a group of related values to represent the item's state?
- Are there any obvious actions to be performed by the item?

If the answers to both of these questions are no, then the noun probably represents a value that can be stored in a simple variable. If we apply this test to each of the nouns that remain in our list, we can conclude that the following are probably not classes: address, estimated labor charges, estimated parts charges, make, model, name, sales tax, telephone number, total estimated charges, and year. These are all simple string or numeric values that can be stored in variables. Here is the updated list of potential classes:

```
address
BMW
ear
cars
customer
estimated labor charges
estimated parts charges
foreign cars
Joe's Automotive Shop
make
manager
Mercedes
model
name
Porsche
sales tax
service quote
shop
telephone number
total estimated charges
year
service quote
```

As you can see from the list, we have eliminated everything except cars, customer, and service quote. This means that in our application, we will need classes to represent cars, customers, and service quotes. Ultimately, we will write a Car class, a Customer class, and a ServiceQuote class.

## Identifying a Class's Responsibilities

Once the classes have been identified, the next task is to identify each class's responsibilities. A class's responsibilities are

- the things that the class is responsible for knowing.
- the actions that the class is responsible for doing.

When you have identified the things that a class is responsible for knowing, then you have identified the class's attributes. Likewise, when you have identified the actions that a class is responsible for doing, you have identified its member functions.

It is often helpful to ask the questions "In the context of this problem, what must the class know? What must the class do?" The first place to look for the answers is in the description of the problem domain. Many of the things a class must know and do will be mentioned. Some class responsibilities, however, might not be directly mentioned in the problem domain, so brainstorming is often required. Let's apply this methodology to the classes we previously identified from our problem domain.

## The Customer class

In the context of our problem domain, what must the Customer class know? The description directly mentions the following items, which are all attributes of a customer:

- the customer's name
- the customer's address
- the customer's telephone number

These are all values that can be represented as strings and stored in the class's member variables. The Customer class can potentially know many other things. One mistake that can be made at this point is to identify too many things that an object is responsible for knowing. In some applications, a Customer class might know the customer's e-mail address. This particular problem domain does not mention that the customer's e-mail address is used for any purpose, so we should not include it as a responsibility.

Now let's identify the class's member functions. In the context of our problem domain, what must the Customer class do? The only obvious actions are to

- create an object of the Customer class.
- set and get the customer's name.
- set and get the customer's address.
- set and get the customer's telephone number.

From this list, we can see that the Customer class will have a constructor, as well as accessor and mutator functions for each of its attributes. Figure 13-23 shows a UML diagram for the Customer class.

## The Car Class

In the context of our problem domain, what must an object of the Car class know? The following items are all attributes of a car and are mentioned in the problem domain:

- the car's make
- the car's model
- the car's year

Figure 13-23 UML diagram for the Customer class

| Customer |
| :--- |
| - name : String |
| - address : String |
| - phone : String |
| + Customer() : |
| + setName(n : String) : void |
| + setAddress(a : String) : void |
| + setPhone(p : String) : void |
| + getName() : String |
| + getAddress() : String |
| $+\operatorname{getPhone():~String~}$ |

Now let's identify the class's member functions. In the context of our problem domain, what must the Car class do? Once again, the only obvious actions are the standard set of member functions that we will find in most classes (constructors, accessors, and mutators). Specifically, the actions are:

- create an object of the Car class
- set and get the car's make
- set and get the car's model
- set and get the car's year

Figure 13-24 shows a UML diagram for the Car class at this point.
Figure 13-24 UML diagram for the Car class

| Car |
| :---: |
| - make : string <br> - model : string <br> - year : int |
| + Car () : <br> + setMake(m : string) : void <br> + setMode1 (m : string) : void <br> + setYear (y : int) : void <br> + getMake() : string <br> + getModel() : string <br> + getYear() : int |

## The ServiceQuote Class

In the context of our problem domain, what must an object of the ServiceQuote class know? The problem domain mentions the following items:

- the estimated parts charges
- the estimated labor charges
- the sales tax
- the total estimated charges

Careful thought and a little brainstorming will reveal that two of these items are the results of calculations: sales tax, and total estimated charges. These items are dependent on the values of the estimated parts and labor charges. In order to avoid the risk of holding stale data, we will not store these values in member variables. Rather, we will provide member functions that calculate these values and return them. The other member functions we will need for this class are a constructor and the accessors and mutators for the estimated parts charges and estimated labor charges attributes. Figure 13-25 shows a UML diagram for the ServiceQuote class.

Figure 13-25 UML diagram for the ServiceQuote class

## This Is Only the Beginning

You should look at the process that we have discussed in this section as merely a starting point. It's important to realize that designing an object-oriented application is an iterative process. It may take you several attempts to identify all of the classes that you will need and determine all of their responsibilities. As the design process unfolds, you will gain a deeper understanding of the problem, and consequently you will see ways to improve the design.

## Checkpoint

13.27 What is a problem domain?
13.28 When designing an object-oriented application, who should write a description of the problem domain?
13.29 How do you identify the potential classes in a problem domain description?
13.30 What are a class's responsibilities?
13.31 What two questions should you ask to determine a class's responsibilities?
13.32 Will all of a class's actions always be directly mentioned in the problem domain description?
13.33 Look at the following description of a problem domain:

A doctor sees patients in her practice. When a patient comes to the practice, the doctor performs one or more procedures on the patient. Each procedure that the doctor performs has a description and a standard fee. As the patient leaves the practice, he or she receives a statement from the office manager. The statement
shows the patient's name and address, as well as the procedures that were performed, and the total charge for the procedures.
Assume you are writing an application to generate a statement that can be printed and given to the patient.
A) Identify all of the potential classes in this problem domain.
B) Refine the list to include only the necessary class or classes for this problem.
C) Identify the responsibilities of the class or classes that you identified in step B.

## Review Questions and Exercises

## Short Answer

1. What is the difference between a class and an instance of the class?
2. What is the difference between the following Person structure and Person class?
```
struct Person
{
    string name;
    int age;
};
class Person
{
    string name;
    int age;
};
```

3. What are the attributes and methods of an object?
4. Look at the following constructor definition:
```
Date :: Date ( int dd = 1, int mm = 1, int yy = 0 );
```

What is the name of the class?
What type of a constructor is this?
5. A contractor uses a blueprint to build a set of identical houses. Are classes analogous to the blueprint or the houses?
6. What is a mutator function? What is an accessor function?
7. Is it a good idea to make member variables private? Why or why not?
8. Can you think of a good reason to avoid writing statements in a class member function that use cout or cin?
9. Under what circumstances should a member function be private?
10. What is a constructor? What is a destructor?
11. What is a default constructor? Is it possible to have more than one default constructor?
12. Is it possible to have more than one constructor? Is it possible to have more than one destructor?
13. If a class object is dynamically allocated in memory, does its constructor execute? If so, when?
14. What does the following statement in an UML class diagram mean?

```
+ getVal(num : int) : void
```

15. What are a class's responsibilities?
16. How do you identify the classes in a problem domain description?

## Fill-in-the-Blank

17. The two common programming methods in practice today are $\qquad$ and
$\qquad$ .
18. Combining data and methods into a single object is called $\qquad$ .
19. $\qquad$ is an object's ability to hide its data from code that is outside the object.
20. $\qquad$ is an object's ability to contain and manipulate its own data.
21. In C++, the $\qquad$ is the construct primarily used to create objects.
22. $\qquad$ specify how class members may be accessed.
23. An object's $\qquad$ defines the values that are stored in the object's attributes at any given moment.
24. The default access specification of class members is $\qquad$ .
25. Classes and $\qquad$ have the same relationship as data types and variables.
26. Defining a class object is often called the $\qquad$ of a class.
27. In the statement double Rectangle::getArea(), Rectangle is the name of the
$\qquad$ and ' $:$ :' is called the $\qquad$ .
28. If you were writing the declaration of a class named Canine, what would you name the file it was stored in? $\qquad$
29. If you were writing the external definitions of the Canine class's member functions, you would save them in a file named $\qquad$ .
30. When a member function's body is written inside a class declaration, the function is
$\qquad$ .
31. A(n) $\qquad$ is automatically called when an object is created.
32. A(n) $\qquad$ is a member function with the same name as the class.
33. $\qquad$ are useful for performing initialization or setup routines in a class object.
34. Constructors cannot have $\mathrm{a}(\mathrm{n})$ $\qquad$ type.
35. In a class without constructors, a $\qquad$ is written during compilation.
36. A(n) $\qquad$ is a member function that is automatically called when an object is destroyed.
37. A destructor has the same name as the class, but is preceded by $a(n)$ $\qquad$ character.
38. Like constructors, destructors cannot have a(n) $\qquad$ type.
39. A constructor whose arguments all have default values is $\mathrm{a}(\mathrm{n})$ $\qquad$ constructor.
40. Defining more than one constructor in a class is called $\qquad$ .
41. A class may only have one default $\qquad$ and one $\qquad$ .
42. $\qquad$ provides a set of standard diagrams for graphically representing objectoriented systems.

## Algorithm Workbench

43. Write a class declaration named Circle with a private member variable named radius. Write set and get functions to access the radius variable, and a function named getArea that returns the area of the circle. The area is calculated as
```
3.14159 * radius * radius
```

44. Add a default constructor to the Circle class in Question 43. The constructor should initialize the radius member to 0 .
45. Add an overloaded constructor to the Circle class in Question 44. The constructor should accept an argument and assign its value to the radius member variable.
46. Write a statement that defines an array of five objects of the Circle class in Question 45. Let the default constructor execute for each element of the array.
47. Write a statement that defines an array of five objects of the Circle class in Question 45. Pass the following arguments to the elements' constructor: $12,7,9,14$, and 8.
48. Write a for loop that displays the radius and area of the circles represented by the array you defined in Question 47.
49. If the items on the following list appeared in a problem domain description, which would be potential classes?

| Animal | Medication | Nurse |
| :--- | :--- | :--- |
| Inoculate | Operate | Advertise |
| Doctor | Invoice | Measure |
| Patient | Client | Customer |

50. Look at the following description of a problem domain:

The bank offers the following types of accounts to its customers: savings accounts, checking accounts, and money market accounts. Customers are allowed to deposit money into an account (thereby increasing its balance), withdraw money from an account (thereby decreasing its balance), and earn interest on the account. Each account has an interest rate.
Assume you are writing an application that will calculate the amount of interest earned for a bank account.
A) Identify the potential classes in this problem domain.
B) Refine the list to include only the necessary class or classes for this problem.
C) Identify the responsibilities of the class or classes.

## True or False

51. T F Private members must be declared before public members.
52. T F Class members are private by default.
53. T F Members of a struct are private by default.
54. T F Classes and structures in C++ are very similar.
55. T F It is mandatory to declare all data members in a class to be private.
56. T F All public members of a class must be declared together.
57. T F It is legal to define a pointer to a class object.
58. T F A const member function cannot modify any data members.
59. T F Private data members cannot be accessed from outside a class unless one knows the password to access it.
60. T F Constructors do not have to have the same name as the class.
61. T F Constructors are automatically executed when an object is created.
62. T F The compiler will report an error if a cin statement is in its body.
63. T F Destructors cannot take arguments.
64. T F Constructors and destructors are executed inline.
65. T F Constructors may have default arguments.
66. T F Member functions may be overloaded.
67. T F Constructors may not be overloaded.
68. T F Constructors and destructors have the same syntax and can only be differentiated from each other through the code that is written in its body.
69. T F A class may only have one destructor.
70. T F When an array of objects is defined, the constructor is only called for the first element.
71. T F If an inline function is called, and the compiler finds that inline expansion is not possible, the compiler ignores the request.
72. T F In an UML diagram, public data members are indicated by a - ' and private data members are indicated by a ' + '.

## Find the Errors

Each of the following class declarations or programs contain errors. Find as many as possible.

```
73. class Triang1e()
    {
    private
        double side1, side2, side3;
    public
        getsides();
        setsides(s1, s2, s2);
        double findarea();
        void display();
    }
74. #include <iostream>
    using namespace std;
    Class Moon;
    {
    Private;
    double earthWeight;
    double moonWeight;
    Public;
    moonWeight(double ew);
        { earthWeight = ew; moonWeight = earthWeight / 6; }
    double getMoonWeight();
        { return moonWeight; }
    }
```

```
    int main()
    {
    double earth;
    cout >> "What is your weight? ";
    cin << earth;
    Moon lunar(earth);
    cout << "On the moon you would weigh "
        <<lunar.getMoonWeight() << endl;
    return 0;
}
75. #include <iostream>
    using namespace std;
    class DumbBe11;
    {
    int weight;
    public:
    void setWeight(int);
};
void setWeight(int w)
{
    weight = w;
}
int main()
{
    DumbBel1 bar;
    DumbBe11(200);
    cout << "The weight is " << bar.weight << endl;
    return 0;
}
76. class List
    {
    int number[20];
    int loop;
    Date()
    { loop = 0; }
    List(int n) ;
};
List :: List (int n)
    {
        1oop = n;
        cout << "Initialize numbers in list ---" << endl;
        for ( int i = 0; i<loop ; i++)
        {
                cout << "Enter number : ";
                cin >> number[i];
        }
    }
```

## Programming Challenges

## 1. Date

Design a class called Date. The class should store a date in three integers: month, day, and year. There should be member functions to print the date in the following forms:

## 12/25/2018

December 25, 2018
25 December 2018
Demonstrate the class by writing a complete program implementing it.
Input Validation: Do not accept values for the day greater than 31 or less than 1. Do not accept values for the month greater than 12 or less than 1.

## 2. Employee Class

Write a class named Employee that has the following member variables:

- name-a string that holds the employee's name
- idNumber-a $n$ int variable that holds the employee's ID number
- department-a string that holds the name of the department where the employee works
- position-a string that holds the employee's job title

The class should have the following constructors:

- A constructor that accepts the following values as arguments and assigns them to the appropriate member variables: employee's name, employee's ID number, department, and position.
- A constructor that accepts the following values as arguments and assigns them to the appropriate member variables: employee's name and ID number. The department and position fields should be assigned an empty string (" ").
- A default constructor that assigns empty strings (" ") to the name, department, and position member variables, and 0 to the idNumber member variable.

Write appropriate mutator functions that store values in these member variables and accessor functions that return the values in these member variables. Once you have written the class, write a separate program that creates three Employee objects to hold the following data:

| Name | ID Number | Department | Position |
| :--- | :--- | :--- | :--- |
| Susan Meyers | 47899 | Accounting | Vice President |
| Mark Jones | 39119 | IT | Programmer |
| Joy Rogers | 81774 | Manufacturing | Engineer |

The program should store this data in the three objects and then display the data for each employee on the screen.

## 3. Car Class

Write a class named Car that has the following member variables:

- yearMode1-an int that holds the car's year model
- make-a string that holds the make of the car
- speed-an int that holds the car's current speed

In addition, the class should have the following constructor and other member functions:

- Constructor-The constructor should accept the car's year model and make as arguments. These values should be assigned to the object's yearModel and make member variables. The constructor should also assign 0 to the speed member variables.
- Accessor-appropriate accessor functions to get the values stored in an object's yearMode1, make, and speed member variables
- accelerate-The accelerate function should add 5 to the speed member variable each time it is called.
- brake-The brake function should subtract 5 from the speed member variable each time it is called.
Demonstrate the class in a program that creates a Car object, then calls the accelerate function five times. After each call to the accelerate function, get the current speed of the car and display it. Then, call the brake function five times. After each call to the brake function, get the current speed of the car and display it.

## 4. Radio Stations

Write a class named BroadcastStation that has member variables for the following data:

- Name of the station
- Frequency
- Type of band (FM or AM)
- The genre of the station (country, sports, rock, classic, etc.)

The BroadcastStation class should have a constructor that accepts an argument for each member variable. The BroadcastStation class should also have accessor and mutator functions for each member variable.
Next, write a class RadioReceiver that represents a basic radio that can store two preset channels. The RadioReceiver class should have member variables for:

- The current volume of the radio
- The name, frequency, and type of the current radio channel
- Two instances of the BroadcastStation class for the two preset channels

The RadioReceiver class should have a constructor with no arguments: all member variables should be initialized to factory default settings. The RadioReceiver class should have accessor and mutator functions for each member variable.
Because in a typical radio the volume and frequency are changed by turning a knob, also supply mutator functions for the volume and frequency that increase and decrease the current value by 1 unit. It should also be possible to store the current radio channel in one of the preset channels, and to change the current radio channel by selecting one of the preset channels.
Also write a function that displays the current state of the RadioReceiver, including the preset channels.
Next, demonstrate the correct working of your classes in a program that creates an instance of the RadioReceiver and then performs actions with the RadioReceiver. Make sure that all information of the RadioReceiver is displayed after each interaction.

## 5. RetailItem Class

Write a class named Retailltem that holds data about an item in a retail store. The class should have the following member variables:

- description-a string that holds a brief description of the item
- unitsOnHand-an int that holds the number of units currently in inventory
- price-a double that holds the item's retail price

Write a constructor that accepts arguments for each member variable, appropriate mutator functions that store values in these member variables, and accessor functions that return the values in these member variables. Once you have written the class, write a separate program that creates three Retailitem objects and stores the following data in them:

|  | Description | Units On Hand | Price |
| :--- | :--- | :--- | :--- |
| Item \#1 | Jacket | 12 | 59.95 |
| Item \#2 | Designer Jeans | 40 | 34.95 |
| Item \#3 | Shirt | 20 | 24.95 |

## 6. Inventory Class

Design an Inventory class that can hold information and calculate data for items in a retail store's inventory. The class should have the following private member variables:

| Variable Name | Description |
| :--- | :--- |
| itemNumber | An int that holds the item's item number. |
| quantity | An int for holding the quantity of the items on hand. |
| cost | A double for holding the wholesale per-unit cost of the item |
| totalcost | A double for holding the total inventory cost of the item <br> (calculated as quantity times cost). |

The class should have the following public member functions:

| Member Function | Description |
| :--- | :--- |
| Default Constructor | Sets all the member variables to 0. <br> Constructor \#2 |
| Accepts an item's number, cost, and quantity as arguments. <br> The function should copy these values to the appropriate <br> member variables and then call the setTotalCost function. |  |
| setItemNumber | Accepts an integer argument that is copied to the <br> itemNumber member variable. |
| setQuantity | Accepts an integer argument that is copied to the <br> quantity member variable. |
| setCost | Accepts a double argument that is copied to the cost <br> member variable. |
| setTotalCost | Calculates the total inventory cost for the item (quantity <br> times cost) and stores the result in totalCost. |
| getItemNumber | Returns the value in itemNumber. |
| getQuantity | Returns the value in quantity. <br> RetCost |
| RetTotalCost the value in cost. |  |$\quad$| Returns the value in totalCost. |
| :--- |

Demonstrate the class in a driver program.
Input Validation: Do not accept negative values for item number, quantity, or cost.

## 7. Length Class

Design a Length class that has two member variables: meters and centimeters. The class should have a constructor, an accessor, and mutator functions for the member variables and a member function getLength() that returns the length in centimeters. Demonstrate the class by writing a separate program that creates two instances of the class. The program should ask the user to enter the lengths in meters and centimeters, which are stored in the Length objects. The program should then compare the lengths of the two objects with the help of the getLength member function.

## 8. Circle Class

Write a Circle class that has the following member variables:

- radius-a double
- pi-a double initialized with the value 3.14159

The class should have the following member functions:

- Default Constructor-a default constructor that sets radius to 0.0
- Constructor-accepts the radius of the circle as an argument
- setRadius-a mutator function for the radius variable
- getRadius-an accessor function for the radius variable
- getArea-returns the area of the circle, which is calculated as

```
area = pi * radius * radius
```

- getDiameter-returns the diameter of the circle, which is calculated as diameter $=$ radius * 2
- getCircumference-returns the circumference of the circle, which is calculated as circumference $=2$ * pi * radius
Write a program that demonstrates the Circle class by asking the user for the circle's radius, creating a Circle object, then reporting the circle's area, diameter, and circumference.

## 9. Number of Visitors

All events have a certain number of visitors permitted. When the maximum number of visitors is reached, nobody can enter unless somebody leaves the premises.
For this purpose, most events implement counter systems that increment the number of people every time somebody enters the event, and decrement the number of people when somebody leaves the event. Typically, the entrance is blocked when the event is fully occupied.
Design a VisitorCounter class that stores both the current and the maximum capacity of the event. The constructor for the class should have one argument: the maximum capacity of the function. For both fields, a member accessor function should be implemented. For the mutator, only functions to add a visitor and to remove a visitor should be implemented. The mutator to add a visitor should return true as long as the maximum capacity is not reached. It should return false when the visitor is not allowed to enter because the maximum capacity has been reached.
Write a program that demonstrates your VisitorCounter class.

## 10. Number Array Class

Design a class that has an array of floating-point numbers. The constructor should accept an integer argument and dynamically allocate the array to hold that many numbers. The destructor should free the memory held by the array. In addition, there should be member functions to perform the following operations:

- Store a number in any element of the array
- Retrieve a number from any element of the array
- Return the highest value stored in the array
- Return the lowest value stored in the array
- Return the average of all the numbers stored in the array

Demonstrate the class in a program.

## 11. Array of Ball Objects

Design a Ball class that has member variables for the radius and color of a ball. The class should have a member function getVolume that returns the volume of the ball. The volume of a sphere with radius $r$ can be calculated using the following formula:
Volume $=\frac{4}{3} \pi r^{3}$
Create an array of five Ball objects. The program should ask the user for the radius and color of each ball object and then display the ball with the maximum volume.

## 12. Draw a Card Simulator

Write a CardDeck class that should have the following member variables:

- allCards : a vector of strings containing all the cards that can be drawn from the deck
- remainingCards : a vector of strings containing all the cards that have not yet been drawn from the deck
The CardDeck class should have the following member functions:
- A default constructor that accepts a vector of strings representing all the cards in the deck. initializes both vectors to have that contents.
- A member function named drawCard() that returns a card from the deck. It generates a random index in the remainingCards vector and that returns the card at that index. It should also remove the drawn card from the remainingCards vector. If the vector becomes empty, the deck must be restarted.
- A void member function named deal () that restarts the deck and initializes the remainingCards vector.
- A member function named get RemainingCards() that returns the number of remaining cards in the deck.
Write a program that demonstrates the CardDeck class. The program should create an instance of the class and draw all cards in the deck. Check if all cards are drawn and whether they appear in a random order.

## 13. Guess the Sequence

For this assignment, you will create a game using the CardDeck class from Programming Challenge 12 (Draw a Card Simulator). The program should have an instance of the CardDeck class where the cards can be alphabetically sorted.
When the game begins, the class draws seven random cards from the deck and displays the first one. The user must then guess whether the next card is lower or higher than
the current card by entering "Lower" or "Higher". When the user guesses correctly, the next card is shown and the game continues.
The player wins when he guesses correctly for all cards. When he makes a wrong estimate, the player should be given the option to restart the current game, start a new game, or to quit.

## 14. Fishing Game Simulation

For this assignment, you will write a program that simulates a fishing game. In this game, a six-sided die is rolled to determine what the user has caught. Each possible item is worth a certain number of fishing points. The points will not be displayed until the user has finished fishing, then a message is displayed congratulating the user depending on the number of fishing points gained.
Here are some suggestions for the game's design:

- Each round of the game is performed as an iteration of a loop that repeats as long as the player wants to fish for more items.
- At the beginning of each round, the program will ask the user whether he or she wants to continue fishing.
- The program simulates the rolling of a six-sided die (use the Die class that was demonstrated in this chapter).
- Each item that can be caught is represented by a number generated from the die. For example, 1 for "a huge fish," 2 for "an old shoe," 3 for "a little fish," and so on.
- Each item the user catches is worth a different amount of points.
- The loop keeps a running total of the user's fishing points.
- After the loop has finished, the total number of fishing points is displayed, along with a message that varies depending on the number of points earned.

## 15. Mortgage Payment

Design a class that will determine the monthly payment on a home mortgage. The monthly payment with interest compounded monthly can be calculated as follows:
Payment $=\frac{\text { Loan } \times \frac{\text { Rate }}{12} \times \text { Term }}{\text { Term }-1}$
where
Term $=\left(1+\frac{\text { Rate }}{12}\right)^{12 \times \text { Years }}$
Payment = the monthly payment
Loan $=$ the dollar amount of the loan
Rate $=$ the annual interest rate
Years $=$ the number of years of the loan
The class should have member functions for setting the loan amount, interest rate, and number of years of the loan. It should also have member functions for returning the monthly payment amount and the total amount paid to the bank at the end of the loan period. Implement the class in a complete program.
Input Validation: Do not accept negative numbers for any of the loan values.
16. Freezing and Boiling Points

The following table lists the freezing and boiling points of several substances.

| Substance | Freezing Point | Boiling Point |
| :--- | :--- | :---: |
| Ethyl alcohol | -173 | 172 |
| Oxygen | -362 | -306 |
| Water | 32 | 212 |

Design a class that stores a temperature in a temperature member variable and has the appropriate accessor and mutator functions. In addition to appropriate constructors, the class should have the following member functions:

- isEthy1Freezing-This function should return the bool value true if the temperature stored in the temperature field is at or below the freezing point of ethyl alcohol. Otherwise, the function should return false.
- isEthy1Boiling-This function should return the bool value true if the temperature stored in the temperature field is at or above the boiling point of ethyl alcohol. Otherwise, the function should return false.
- isOxygenFreezing-This function should return the bool value true if the temperature stored in the temperature field is at or below the freezing point of oxygen. Otherwise, the function should return false.
- isOxygenBoiling-This function should return the bool value true if the temperature stored in the temperature field is at or above the boiling point of oxygen. Otherwise, the function should return false.
- isWaterFreezing-This function should return the bool value true if the temperature stored in the temperature field is at or below the freezing point of water. Otherwise, the function should return false.
- isWaterBoiling-This function should return the bool value true if the temperature stored in the temperature field is at or above the boiling point of water. Otherwise, the function should return false.
Write a program that demonstrates the class. The program should ask the user to enter a temperature, then display a list of the substances that will freeze at that temperature, and those that will boil at that temperature. For example, if the temperature is -20 the class should report that water will freeze and oxygen will boil at that temperature.

## 17. Time Class

Design a class Time that represents time in 12-hour format. The class should store time in four variables:

- hours
- minutes
- seconds
- am_pm that determines whether it is am or pm

The class should have member variables to input time in 12 -hour format. It should display time in the following two formats:

1. 12-hour format (e.g., 8:15:33 pm)
2. 24-hour format (e.g., 20:15:33)

Demonstrate the class in a complete program.

Input Validation: Accept hours only within the range of 0 to 12. Accept minutes and seconds only within the range of 0 to 59. Accept only the values "am" or "pm" for am_pm. If the hour is 12, the user should not be asked to input the value of am_pm; instead am_pm should be automatically assigned " $p m$ ".

## 18. A Game of 21

For this assignment, you will write a program that lets the user play against the computer in a variation of the popular blackjack card game. In this variation of the game, two six-sided dice are used instead of cards. The dice are rolled, and the player tries to beat the computer's hidden total without going over 21.
Here are some suggestions for the game's design:

- Each round of the game is performed as an iteration of a loop that repeats as long as the player agrees to roll the dice, and the player's total does not exceed 21.
- At the beginning of each round, the program will ask the users whether they want to roll the dice to accumulate points.
- During each round, the program simulates the rolling of two six-sided dice. It rolls the dice first for the computer, then it asks the user if he or she wants to roll. (Use the Die class demonstrated in this chapter to simulate the dice).
- The loop keeps a running total of both the computer and the user's points.
- The computer's total should remain hidden until the loop has finished.
- After the loop has finished, the computer's total is revealed, and the player with the most points without going over 21 wins.

## 19. Trivia Game

In this programming challenge, you will create a simple trivia game for two players. The program will work like this:

- Starting with player 1 , each player gets a turn at answering five trivia questions. (There are a total of 10 questions.) When a question is displayed, four possible answers are also displayed. Only one of the answers is correct, and if the player selects the correct answer, he or she earns a point.
- After answers have been selected for all of the questions, the program displays the number of points earned by each player and declares the player with the highest number of points the winner.
In this program, you will design a Question class to hold the data for a trivia question. The Question class should have member variables for the following data:
- A trivia question
- Possible answer \#1
- Possible answer \#2
- Possible answer \#3
- Possible answer \#4
- The number of the correct answer ( $1,2,3$, or 4 )

The Question class should have appropriate constructor(s), accessor, and mutator functions.
The program should create an array of 10 Question objects, one for each trivia question. Make up your own trivia questions on the subject or subjects of your choice for the objects.

## Group Project

## 20. Patient Fees

1. This program should be designed and written by a team of students. Here are some suggestions:

- One or more students may work on a single class.
- The requirements of the program should be analyzed so that each student is given about the same workload.
- The parameters and return types of each function and class member function should be decided in advance.
- The program will be best implemented as a multi-file program.

2. You are to write a program that computes a patient's bill for a hospital stay. The different components of the program are
The PatientAccount class
The Surgery class
The Pharmacy class
The main program

- The PatientAccount class will keep a total of the patient's charges. It will also keep track of the number of days spent in the hospital. The group must decide on the hospital's daily rate.
- The Surgery class will have stored within it the charges for at least five types of surgery. It can update the charges variable of the PatientAccount class.
- The Pharmacy class will have stored within it the price of at least five types of medication. It can update the charges variable of the PatientAccount class.
- The student who designs the main program will design a menu that allows the user to enter a type of surgery and a type of medication, and check the patient out of the hospital. When the patient checks out, the total charges should be displayed.

### 14.1 Instance and Static Members

CONCEPT: Each instance of a class has its own copies of the class's instance variables. If a member variable is declared static, however, all instances of that class have access to that variable. If a member function is declared static, it may be called without any instances of the class being defined.

## Instance Variables

Each class object (an instance of a class) has its own copy of the class's member variables. An object's member variables are separate and distinct from the member variables of other objects of the same class. For example, recall that the Rectangle class discussed in Chapter 13 has two member variables: width and length. Suppose we define two objects of the Rectangle class and set their width and length member variables as shown in the following code.

```
Rectangle box1, box2;
// Set the width and length for box1.
box1.setWidth(5);
box1.setLength(10);
// Set the width and length for box2.
box2.setWidth(500);
box2.setLength(1000);
```

This code creates box1 and box2, which are two distinct objects. Each has its own width and length member variables, as illustrated in Figure 14-1.
Figure 14-1 Two objects

When the getWidth member function is called, it returns the value stored in the calling object's width member variable. For example, the following statement displays 5500.

```
cout << box1.getWidth() << " " << box2.getWidth() << endl;
```

In object-oriented programming, member variables such as the Rectangle class's width and length members are known as instance variables. They are called instance variables because each instance of the class has its own copies of the variables.

## Static Members

It is possible to create a member variable or member function that does not belong to any instance of a class. Such members are known as static member variables and static member functions. When a value is stored in a static member variable, it is not stored in an instance of the class. In fact, an instance of the class doesn't even have to exist in order for values to be stored in the class's static member variables. Likewise, static member functions do not operate on instance variables. Instead, they can operate only on static member variables. You can think of static member variables and static member functions as belonging to the class instead of to an instance of the class. In this section, we will take a closer look at static members. First, we will examine static member variables.

## Static Member Variables

When a member variable is declared with the key word static, there will be only one copy of the member variable in memory, regardless of the number of instances of the class that might exist. A single copy of a class's static member variable is shared by all instances of the class. For example, the following Tree class uses a static member variable to keep count of the number of instances of the class that are created.

## Contents of Tree.h

```
// Tree class
class Tree
{
private:
    static int objectCount; // Static member variable.
public:
    // Constructor
    Tree()
            { objectCount++; }
```

10

```
    // Accessor function for objectCount
    int getObjectCount() const
        { return objectCount; }
};
// Definition of the static member variable, written
// outside the class.
int Tree::objectCount = 0;
```

First, notice in line 5 the declaration of the static member variable named objectCount: A static member variable is created by placing the key word static before the variable's data type. Also notice in line 18 , we have written a definition statement for the objectCount variable, and that the statement is outside the class declaration. This external definition statement causes the variable to be created in memory, and is required. In line 18, we have explicitly initialized the objectCount variable with the value 0 . We could have left out the initialization because C++ automatically stores 0 in all uninitialized static member variables. It is a good practice to initialize the variable anyway, so it is clear to anyone reading the code that the variable starts out with the value 0 .

Next, look at the constructor in lines 8 and 9 . In line 9 , the ++ operator is used to increment objectCount. Each time an instance of the Tree class is created, the constructor will be called, and the objectCount member variable will be incremented. As a result, the objectCount member variable will contain the number of instances of the Tree class that have been created. The getObjectCount function, in lines 12 and 13 , returns the value in objectCount. Program 14-1 demonstrates this class.

## Program 14-1

// This program demonstrates a static member variable.
\#include <iostream>
\#include "Tree.h"
using namespace std;

```
int main()
```

\{
// Define three Tree objects.
Tree oak;
Tree elm;
Tree pine;
// Display the number of Tree objects we have.
cout << "We have " << pine.getObjectCount()
<< " trees in our program!\n";
return 0 ;
\}

## Program Output

We have 3 trees in our program!
The program creates three instances of the Tree class, stored in the variables oak, elm, and pine. Although there are three instances of the class, there is only one copy of the static objectCount variable. This is illustrated in Figure 14-2.

Figure 14-2 A static variable

In line 14, the program calls the getObjectCount member function to retrieve the number of instances that have been created. Although the program uses the pine object to call the member function, the same value would be returned if any of the objects had been used. For example, all three of the following cout statements would display the same thing:

```
cout << "We have " << oak.getObjectCount() << " trees\n";
cout << "We have " << elm.getObjectCount() << " trees\n";
cout << "We have " << pine.getObjectCount() << " trees\n";
```

A more practical use of a static member variable is demonstrated in Program 14-2. The Budget class is used to gather the budget requests for all the divisions of a company. The class uses a static member, corpBudget, to hold the amount of the overall corporate budget. When the member function addBudget is called, its argument is added to the current contents of corpBudget. By the time the program is finished, corpBudget will contain the total of all the values placed there by all the Budget class objects. (These files can be found in the Student Source Code Folder Chapter 14\Budget Version 1.)

## Contents of Budget.h (Version 1)

```
#ifndef BUDGET_H
#define BUDGET_H
// Budget class declaration
class Budget
{
private:
    static double corpBudget; // Static member
    double divisionBudget; // Instance member
public:
    Budget()
        { divisionBudget = 0; }
    void addBudget(double b)
            { divisionBudget += b;
                corpBudget += b; }
            double getDivisionBudget() const
            { return divisionBudget; }
```

```
            double getCorpBudget() const
            { return corpBudget; }
};
// Definition of static member variable corpBudget
double Budget::corpBudget = 0;
#endif
```

## Program 14-2

```
// This program demonstrates a static class member variable.
#include <iostream>
#include <iomanip>
#include "Budget.h"
using namespace std;
int main()
{
    int count; // Loop counter
    const int NUM_DIVISIONS = 4; // Number of divisions
    Budget divisions[NUM_DIVISIONS]; // Array of Budget objects
    // Get the budget requests for each division.
    for (count = 0; count < NUM_DIVISIONS; count++)
    {
        double budgetAmount;
        cout << "Enter the budget request for division ";
        cout << (count + 1) << ": ";
        cin >> budgetAmount;
        divisions[count].addBudget(budgetAmount);
    }
    // Display the budget requests and the corporate budget.
    cout << fixed << showpoint << setprecision(2);
    cout << "\nHere are the division budget requests:\n";
    for (count = 0; count < NUM_DIVISIONS; count++)
    {
        cout << "\tDivision " << (count + 1) << "\t$ ";
        cout << divisions[count].getDivisionBudget() << endl;
    }
    cout << "\tTotal Budget Requests:\t$ ";
    cout << divisions[0].getCorpBudget() << endl;
    return 0;
}
```

Program Output with Example Input Shown in Bold
Enter the budget request for division 1: $\mathbf{1 0 0 0 0 0}$ Enter
Enter the budget request for division 2: 200000 Enter
Enter the budget request for division 3: $\mathbf{3 0 0 0 0 0}$ Enter
Enter the budget request for division 4: $\mathbf{4 0 0 0 0 0}$ Enter

## Program 14-2 <br> (continued)

```
Here are the division budget requests:
    Division 1 $ 100000.00
    Division 2 $ 200000.00
    Division 3 $ 300000.00
    Division 4 $ 400000.00
    Tota1 Budget Requests: $ 1000000.00
```

## Static Member Functions

You declare a static member function by placing the static keyword in the function's prototype. Here is the general form:

```
static ReturnType FunctionName (ParameterTypeList);
```

A function that is a static member of a class cannot access any nonstatic member data in its class. With this limitation in mind, you might wonder what purpose static member functions serve. The following two points are important for understanding their usefulness:

1. Even though static member variables are declared in a class, they are actually defined outside the class declaration. The lifetime of a class's static member variable is the lifetime of the program. This means that a class's static member variables come into existence before any instances of the class are created.
2. A class's static member functions can be called before any instances of the class are created. This means that a class's static member functions can access the class's static member variables before any instances of the class are defined in memory. This gives you the ability to create very specialized setup routines for class objects.

Program 14-3, a modification of Program 14-2, demonstrates this feature. It asks the user to enter the main office's budget request before any division requests are entered. The Budget class has been modified to include a static member function named mainOffice. This function adds its argument to the static corpBudget variable, and is called before any instances of the Budget class are defined. (These files can be found in the Student Source Code Folder Chapter 14\Budget Version 2.)

## Contents of Budget.h (Version 2)

```
#ifndef BUDGET_H
#define BUDGET_H
// Budget class declaration
class Budget
{
private:
    static double corpBudget; // Static member variable
    double divisionBudget; // Instance member variable
public:
    Budget()
                { divisionBudget = 0; }
```

```
    void addBudget(double b)
        { divisionBudget += b;
            corpBudget += b; }
    double getDivisionBudget() const
    { return divisionBudget; }
    double getCorpBudget() const
        { return corpBudget; }
    static void mainOffice(double); // Static member function
};
#endif
```

## Contents of Budget.cpp

```
#include "Budget.h"
// Definition of corpBudget static member variable
double Budget::corpBudget = 0;
/l**************************************************************
// Definition of static member function mainOffice. *
// This function adds the main office's budget request to *
// the corpBudget variable.
//*************************************************************
void Budget::mainOffice(double moffice)
{
        corpBudget += moffice;
}
```

## Program 14-3

```
// This program demonstrates a static member function.
#include <iostream>
#include <iomanip>
#include "Budget.h"
using namespace std;
int main()
{
    int count; // Loop counter
    double mainOfficeRequest; // Main office budget request
    const int NUM_DIVISIONS = 4; // Number of divisions
    // Get the main office's budget request.
    // Note that no instances of the Budget class have been defined.
    cout << "Enter the main office's budget request: ";
    cin >> mainOfficeRequest;
    Budget::mainOffice(mainOfficeRequest);
```

```
Program 14-3 (continued)
19 Budget divisions[NUM_DIVISIONS]; // An array of Budget objects.
```

```
    // Get the budget requests for each division.
    for (count = 0; count < NUM_DIVISIONS; count++)
    {
    double budgetAmount;
    cout << "Enter the budget request for division ";
    cout << (count + 1) << ": ";
    cin >> budgetAmount;
    divisions[count].addBudget(budgetAmount);
}
    // Display the budget requests and the corporate budget.
    cout << fixed << showpoint << setprecision(2);
    cout << "\nHere are the division budget requests:\n";
    for (count = 0; count < NUM_DIVISIONS; count++)
    {
        cout << "\tDivision " << (count + 1) << "\t$ ";
        cout << divisions[count].getDivisionBudget() << endl;
        }
        cout << "\tTota1 Budget Requests:\t$ ";
        cout << divisions[0].getCorpBudget() << endl;
        return 0;
}
```

## Program Output with Example Input Shown in Bold

Enter the main office's budget request: 100000 Enter
Enter the budget request for division 1: 100000 Enter
Enter the budget request for division 2: 200000 Enter
Enter the budget request for division 3: $\mathbf{3 0 0 0 0 0}$ Enter
Enter the budget request for division 4: 400000 Enter
Here are the division budget requests:
Division 1 \$ 100000.00
Division 2 \$ 200000.00
Division 3 \$ 300000.00
Division 4 \$400000.00
Total Requests (including main office): \$ 1100000.00
Notice in line 17 the statement that calls the static function mainOffice:

```
Budget::mainOffice(amount);
```

Calls to static member functions do not use the regular notation of connecting the function name to an object name with the dot operator. Instead, static member functions are called by connecting the function name to the class name with the scope resolution operator.

NOTE: If an instance of a class with a static member function exists, the static member function can be called with the class object name and the dot operator, just like any other member function.

### 14.2 Friends of Classes

CONCEPT: A friend is a function or class that is not a member of a class, but has access to the private members of the class.

Private members are hidden from all parts of the program outside the class, and accessing them requires a call to a public member function. Sometimes you will want to create an exception to that rule. A friend function is a function that is not part of a class, but that has access to the class's private members. In other words, a friend function is treated as if it were a member of the class. A friend function can be a regular stand-alone function, or it can be a member of another class. (In fact, an entire class can be declared a friend of another class.)

In order for a function or class to become a friend of another class, it must be declared as such by the class granting it access. Classes keep a "list" of their friends, and only the external functions or classes whose names appear in the list are granted access. A function is declared a friend by placing the key word friend in front of a prototype of the function. Here is the general format:

```
friend ReturnType FunctionName (ParameterTypeList)
```

In the following declaration of the Budget class, the addBudget function of another class, AuxiliaryOffice has been declared a friend. (This file can be found in the Student Source Code Folder Chapter 14\Budget Version 3.)

## Contents of Budget.h (Version 3)

```
#ifndef BUDGET_H
#define BUDGET_H
#include "Auxil.h"
// Budget class declaration
class Budget
{
private:
    static double corpBudget; // Static member variable
    double divisionBudget; // Instance member variable
public:
        Budget()
            { divisionBudget = 0; }
    void addBudget(double b)
            { divisionBudget += b;
                corpBudget += b; }
    double getDivisionBudget() const
            { return divisionBudget; }
        double getCorpBudget() const
            { return corpBudget; }
```

```
    // Static member function
    static void mainOffice(double);
    // Friend function
    friend void AuxiliaryOffice::addBudget(double, Budget &);
    };
    #endif
```

Let's assume another class, AuxiliaryOffice, represents a division's auxiliary office, perhaps in another country. The auxiliary office makes a separate budget request, which must be added to the overall corporate budget. The friend declaration of the AuxiliaryOffice: :addBudget function tells the compiler that the function is to be granted access to Budget's private members. Notice the function takes two arguments: a double and a reference object of the Budget class. The Budget class object that is to be modified by the function is passed to it, by reference, as an argument. The following code shows the declaration of the AuxillaryOffice class. (This file can be found in the Student Source Code Folder Chapter 14\Budget Version 3.)

## Contents of Auxil.h

```
#ifndef AUXIL_H
#define AUXIL_H
class Budget; // Forward declaration of Budget class
// Aux class declaration
class AuxiliaryOffice
{
private:
    double auxBudget;
public:
    AuxiliaryOffice()
        { auxBudget = 0; }
    double getDivisionBudget() const
            { return auxBudget; }
        void addBudget(double, Budget &);
};
#endif
```

## Contents of Auxil.cpp

```
#include "Auxil.h"
#include "Budget.h"
|/************************************************************
// Definition of member function mainOffice.
// This function is declared a friend by the Budget class. *
// It adds the value of argument b to the static corpBudget *
// member variable of the Budget class.
|l***************************************************************
```

```
void AuxiliaryOffice::addBudget(double b, Budget &div)
{
    auxBudget += b;
    div.corpBudget += b;
}
```

Notice the Auxil.h file contains the following statement in line 4:

```
class Budget; // Forward declaration of Budget class
```

This is a forward declaration of the Budget class. It simply tells the compiler that a class named Budget will be declared later in the program. This is necessary because the compiler will process the Auxil.h file before it processes the Budget class declaration. When it is processing the Auxil.h file, it will see the following function declaration in line 19:

```
void addBudget(double, Budget &);
```

The addBudget function's second parameter is a Budget reference variable. At this point, the compiler has not processed the Budget class declaration, so, without the forward declaration, it wouldn't know what a Budget reference variable is.
The following code shows the definition of the addBudget function. (This file can be found in the Student Source Code Folder Chapter 14\Budget Version 3.)

## Contents of Auxi 1. cpp

```
#include "Auxil.h"
#include "Budget.h"
//*********************************************
// This function is declared a friend by the Budget class. *
// It adds the value of argument b to the static corpBudget *
// member variable of the Budget class.
|/**************************************************************
void AuxiliaryOffice::addBudget(double b, Budget &div)
{
        auxBudget += b;
        div.corpBudget += b;
}
```

The parameter div, a reference to a Budget class object, is used in line 14. This statement adds the parameter $b$ to div.corpBudget. Program 14-4 demonstrates the classes.

## Program 14-4

// This program demonstrates a static member function.
\#include <iostream>
\#include <iomanip>
\#include "Budget.h"
using namespace std;

## Program 14-4 (continued)

```
int main()
{
    int count; // Loop counter
    double mainOfficeRequest; // Main office budget request
    const int NUM_DIVISIONS = 4; // Number of divisions
    // Get the main office's budget request.
    cout << "Enter the main office's budget request: ";
    cin >> mainOfficeRequest;
    Budget::mainOffice(mainOfficeRequest);
    Budget divisions[NUM_DIVISIONS]; // Array of Budget objects
    AuxiliaryOffice auxOffices[4]; // Array of AuxiliaryOffice
    // Get the budget requests for each division
    // and their auxiliary offices.
    for (count = 0; count < NUM_DIVISIONS; count++)
    {
        double budgetAmount; // To hold input
        // Get the request for the division office.
        cout << "Enter the budget request for division ";
        cout << (count + 1) << ": ";
        cin >> budgetAmount;
        divisions[count].addBudget(budgetAmount);
        // Get the request for the auxiliary office.
        cout << "Enter the budget request for that division's\n";
        cout << "auxiliary office: ";
        cin >> budgetAmount;
        auxOffices[count].addBudget(budgetAmount, divisions[count]);
    }
    // Display the budget requests and the corporate budget.
    cout << fixed << showpoint << setprecision(2);
    cout << "\nHere are the division budget requests:\n";
    for (count = 0; count < NUM_DIVISIONS; count++)
    {
        cout << "\tDivision " << (count + 1) << "\t\t$";
        cout << divisions[count].getDivisionBudget() << endl;
        cout << "\tAuxiliary office:\t$";
        cout << auxOffices[count].getDivisionBudget() << endl << endl;
    }
        cout << "Total Budget Requests:\t$ ";
        cout << divisions[0].getCorpBudget() << endl;
        return 0;
}
```

```
Program Output with Example Input Shown in Bold
Enter the main office's budget request: 100000 Enter
Enter the budget request for division 1: 100000 Enter
Enter the budget request for that division's
auxiliary office: 50000 Enter
Enter the budget request for division 2: 200000 Enter
Enter the budget request for that division's
auxiliary office: 40000 Enter
Enter the budget request for division 3: 300000 Enter
Enter the budget request for that division's
auxiliary office: }70000\mathrm{ Enter
Enter the budget request for division 4: 400000 Enter
Enter the budget request for that division's
auxiliary office: 65000 Enter
Here are the division budget requests:
    Division 1 $100000.00
    Auxiliary office: $50000.00
    Division 2 $200000.00
    Auxiliary office: $40000.00
    Division 3 $300000.00
    Auxiliary office: $70000.00
    Division 4 $400000.00
    Auxiliary office: $65000.00
Tota1 Budget Requests: $ 1325000.00
```

As mentioned before, it is possible to make an entire class a friend of another class. The Budget class could make the AuxiliaryOffice class its friend with the following declaration:

```
friend class AuxiliaryOffice;
```

This may not be a good idea, however. Every member function of AuxiliaryOffice (including ones that may be added later) would have access to the private members of Budget. The best practice is to declare as friends only those functions that must have access to the private members of the class.

## Checkpoint

14.1 What is the difference between an instance member variable and a static member variable?
14.2 Static member variables are declared inside the class declaration. Where do you write the definition statement for a static member variable?
14.3 Does a static member variable come into existence in memory before, at the same time as, or after any instances of its class?
14.4 What limitation does a static member function have?
14.5 What action is possible with a static member function that isn't possible with an instance member function?
14.6 If class $X$ declares function $f$ as a friend, does function $f$ become a member of class $X$ ?
14.7 Class $Y$ is a friend of class $X$, which means the member functions of class $Y$ have access to the private members of class $X$. Does the friend key word appear in class $Y$ 's declaration or in class X's declaration?

### 14.3 Memberwise Assignment

CONCEPT: The = operator may be used to assign one object's data to another object, or to initialize one object with another object's data. By default, each member of one object is copied to its counterpart in the other object.

Like other variables (except arrays), objects may be assigned to one another using the = operator. As an example, consider Program 14-5, which uses the Rectangle class (version 4) we discussed in Chapter 13. Recall that the Rectangle class has two member variables: width and length. The constructor accepts two arguments: one for width, and one for length.

## Program 14-5

```
// This program demonstrates memberwise assignment.
#include <iostream>
#include "Rectangle.h"
using namespace std;
int main()
{
    // Define two Rectangle objects.
    Rectangle box1(10.0, 10.0); // width = 10.0, length = 10.0
    Rectangle box2 (20.0, 20.0); // width = 20.0, length = 20.0
    // Display each object's width and length.
    cout << "box1's width and length: " << box1.getWidth()
        << " " << box1.getLength() << endl;
    cout << "box2's width and length: " << box2.getWidth()
        << " " << box2.getLength() << endl << endl;
    // Assign the members of box1 to box2.
    box2 = box1;
    // Display each object's width and length again.
    cout << "box1's width and length: " << box1.getWidth()
        << " " << box1.getLength() << endl;
    cout << "box2's width and length: " << box2.getWidth()
        << " " << box2.getLength() << endl;
    return 0;
}
```

```
Program Output
box1's width and length: 10 10
box2's width and length: 20 20
box1's width and length: 10 10
box2's width and length: 10 10
```

The following statement, which appears in line 19 , copies the width and 1ength member variables of box1 directly into the width and length member variables of box2:

```
box2 = box1;
```

Memberwise assignment also occurs when one object is initialized with another object's values. Remember the difference between assignment and initialization: assignment occurs between two objects that already exist, and initialization happens to an object being created. Consider the following code:

```
// Define box1.
Rectangle box1(100.0, 50.0);
// Define box2, initialize with box1's values
Rectang1e box2 = box1;
```

The last statement defines a Rectangle object, box2, and initializes it to the values stored in box1. Because memberwise assignment takes place, the box 2 object will contain the exact same values as the box1 object.

### 14.4 Copy Constructors

CONCEPT: A copy constructor is a special constructor that is called whenever a new object is created and initialized with another object's data.

Sometimes the default memberwise assignment behavior in C++ is perfectly acceptable. There are many situations, however, where memberwise assignment cannot be used. For example, consider the following class. (This file can be found in the Student Source Code Folder Chapter 14\StudentTestScores Version 1.)

## Contents of StudentTestScores.h (Version 1)

```
#ifndef STUDENTTESTSCORES_H
#define STUDENTTESTSCORES_H
#include <string>
using namespace std;
const double DEFAULT_SCORE = 0.0;
class StudentTestScores
{
private:
    string studentName; // The student's name
        double *testScores; // Points to array of test scores
        int numTestScores; // Number of test scores
        // Private member function to create an
        // array of test scores.
        void createTestScoresArray(int size)
        { numTestScores = size;
            testScores = new double[size];
            for (int i = 0; i < size; i++)
                    testScores[i] = DEFAULT_SCORE;}
```

```
pub1ic:
    // Constructor
    StudentTestScores(string name, int numScores)
    { studentName = name;
        createTestScoresArray(numScores); }
    // Destructor
    ~StudentTestScores()
    { delete [] testScores; }
    // The setTestScore function sets a specific
    // test score's value.
    void setTestScore(double score, int index)
    { testScores[index] = score; }
    // Set the student's name.
    void setStudentName(string name)
    { studentName = name; }
    // Get the student's name.
    string getStudentName() const
    { return studentName; }
    // Get the number of test scores.
    int getNumTestScores() const
    { return numTestScores; }
    // Get a specific test score.
    double getTestScore(int index) const
    { return testScores[index]; }
};
#endif
```

This class stores a student's name and a set of test scores. Let's take a closer look at the code:

- Lines 11 through 13 declare the class's attributes. The studentName attribute is a string object that holds a student's name. The testScores attribute is an int pointer. Its purpose is to point to a dynamically allocated int array that holds the student's test score. The numTestScore attribute is an int that holds the number of test scores.
- The createTestScoresArray private member function, in lines 17 through 21 , creates an array to hold the student's test scores. It accepts an argument for the number of test scores, assigns this value to the numTestScores attribute (line 18), then dynamically allocates an int array for the testScores attribute (line 19). The for loop in lines 20 and 21 initializes each element of the array to the default value 0.0 .
- The constructor, in lines 25 through 27 , accepts the student's name and the number of test scores as arguments. In line 26 , the name is assigned to the studentName attribute, and in line 27 the number of test scores is passed to the createTestScoresArray member function.
- The destructor, in lines 30 and 31, deallocates the testScores array.
- The setTestScore member function, in lines 35 and 36 , sets a specific score in the testScores attribute. The function accepts arguments for the score and the index where the score should be stored in the testScores array.
- The setStudentName member function, in lines 39 and 40 , accepts an argument that is assigned to the studentName attribute.
- The getStudentName member function, in lines 43 and 44 , returns the value of the studentName attribute.
- The getNumTestScores member function, in lines 47 and 48 , returns the number of test scores stored in the object.
- The getTestScore member function, in lines 51 and 52 , returns a specific score (specified by the index parameter) from the testScores attribute.

A potential problem with this class lies in the fact that one of its members, testScores, is a pointer. The createTestScoresArray member function (called by the constructor) performs a critical operation with the pointer: It dynamically allocates a section of memory for the testScores array and assigns default values to each of its element. For instance, the following statement creates a StudentTestScores object named student1, whose testScores member references dynamically allocated memory holding an array of 5 double's:

```
StudentTestScores("Maria Jones Tucker", 5);
```

This is depicted in Figure 14-3.

Figure 14-3 The testScores member referencing a dynamically allocated array

Consider what happens when another StudentTestScores object is created and initialized with the student1 object, as in the following statement:

```
StudentTestScores student2 = student1;
```

In the statement above, student2's constructor isn't called. Instead, memberwise assignment takes place, copying each of student1's member variables into student2. This means that a separate section of memory is not allocated for student2's testScores member. It simply gets a copy of the address stored in student1's testScores member. Both pointers will point to the same address, as depicted in Figure 14-4.

Figure 14-4 Two pointers pointing to the same array

In this situation, either object can manipulate the values stored in the array, causing the changes to show up in the other object. Likewise, one object can be destroyed, causing its destructor to be called, which frees the allocated memory. The remaining object's testScores pointer would still reference this section of memory, although it should no longer be used.

The solution to this problem is to create a copy constructor for the object. A copy constructor is a special constructor that's called when an object is initialized with another object's data. It has the same form as other constructors, except it has a reference parameter of the same class type as the object itself. For example, here is a copy constructor for the StudentTestScores class:

```
StudentTestScores(StudentTestScores &obj)
{ studentName = obj.studentName;
    numTestScores = obj.numTestScores;
    testScores = new double[numTestScores];
    for (int i = 0; i < length; i++)
        testScores[i] = obj.testScores[i]; }
```

When the = operator is used to initialize a StudentTestScores object with the contents of another StudentTestScores object, the copy constructor is called. The StudentTestScores object that appears on the right side of the $=$ operator is passed as an argument to the copy constructor. For example, look at the following statement:

```
StudentTestScores student1 ("Molly McBride", 8);
StudentTestScores student2 = student1;
```

In this code, the student1 object is passed as an argument to the student2 object's copy constructor.

NOTE: C++ requires that a copy constructor's parameter be a reference object.

As you can see from studying the copy constructor's code, student2's testScores member will properly reference its own dynamically allocated memory. There will be no danger of student1 inadvertently destroying or corrupting student2's data.

## Using const Parameters in Copy Constructors

Because copy constructors are required to use reference parameters, they have access to their argument's data. Since the purpose of a copy constructor is to make a copy of the argument, there is no reason the constructor should modify the argument's data. With this in mind, it's a good idea to make copy constructors' parameters constant by specifying the const key word in the parameter list. Here is an example:

```
StudentTestScores(const StudentTestScores &obj)
{ studentName = obj.studentName;
    numTestScores = obj.numTestScores;
    testScores = new double[numTestScores];
    for (int i = 0; i < numTestScores; i++)
            testScores[i] = obj.testScores[i]; }
```

The const key word ensures that the function cannot change the contents of the parameter. This will prevent you from inadvertently writing code that corrupts data.

The complete listing for the revised StudentTestScores class is shown here. (This file can be found in the Student Source Code Folder Chapter 14\StudentTestScores Version 2.)

## Contents of StudentTestScores.h (Version 2)

```
#ifndef STUDENTTESTSCORES_H
#define STUDENTTESTSCORES_H
#include <string>
using namespace std;
const double DEFAULT_SCORE = 0.0;
class StudentTestScores
{
private:
    string studentName; // The student's name
    double *testScores; // Points to array of test scores
    int numTestScores; // Number of test scores
    // Private member function to create an
    // array of test scores.
    void createTestScoresArray(int size)
    { numTestScores = size;
        testScores = new double[size];
        for (int i = 0; i < size; i++)
            testScores[i] = DEFAULT_SCORE; }
pub1ic:
    // Constructor
    StudentTestScores(string name, int numScores)
    { studentName = name;
        createTestScoresArray(numScores); }
    // Copy constructor
    StudentTestScores(const StudentTestScores &obj)
    { studentName = obj.studentName;
        numTestScores = obj.numTestScores;
        testScores = new double[numTestScores];
        for (int i = 0; i < numTestScores; i++)
            testScores[i] = obj.testScores[i]; }
    // Destructor
    ~StudentTestScores()
    { delete [] testScores; }
    // The setTestScore function sets a specific
    // test score's value.
    void setTestScore(double score, int index)
    { testScores[index] = score; }
```

```
    // Set the student's name.
    void setStudentName(string name)
    { studentName = name; }
    // Get the student's name.
    string getStudentName() const
    { return studentName; }
    // Get the number of test scores.
    int getNumTestScores() const
    { return numTestScores; }
    // Get a specific test score.
    double getTestScore(int index) const
    { return testScores[index]; }
};
#endif
```

## Copy Constructors and Function Parameters

When a class object is passed by value as an argument to a function, it is passed to a parameter that is also a class object, and the copy constructor of the function's parameter is called. Remember that when a nonreference class object is used as a function parameter, it is created when the function is called, and it is initialized with the argument's value.
This is why C++ requires the parameter of a copy constructor to be a reference object. If an object were passed to the copy constructor by value, the copy constructor would create a copy of the argument and store it in the parameter object. When the parameter object is created, its copy constructor will be called, thus causing another parameter object to be created. This process will continue indefinitely (or at least until the available memory fills up, causing the program to halt).
To prevent the copy constructor from calling itself an infinite number of times, C++ requires its parameter to be a reference object.

## The Default Copy Constructor

Although you may not realize it, you have seen the action of a copy constructor before. If a class doesn't have a copy constructor, C++ creates a default copy constructor for it. The default copy constructor performs the memberwise assignment discussed in the previous section.

## Checkpoint

14.8 Briefly describe what is meant by memberwise assignment.
14.9 Describe two instances when memberwise assignment occurs.
14.10 Describe a situation in which memberwise assignment should not be used.
14.11 When is a copy constructor called?
14.12 How does the compiler know that a member function is a copy constructor?
14.13 What action is performed by a class's default copy constructor?

### 14.5 Operator Overlloading <br> CONCEPT: C++ allows you to redefine how standard operators work when used with class objects.

VideoNote Operator Overloading

C++ provides many operators to manipulate data of the primitive data types. However, what if you wish to use an operator to manipulate class objects? For example, assume that a class named Date exists, and objects of the Date class hold the month, day, and year in member variables. Suppose the Date class has a member function named add. The add member function adds a number of days to the date and adjusts the member variables if the date goes to another month or year. For example, the following statement adds 5 days to the date stored in the today object:

```
today.add(5);
```

Although it might be obvious that the statement is adding 5 days to the date stored in today, the use of an operator might be more intuitive. For example, look at the following statement:

```
today += 5;
```

This statement uses the standard += operator to add 5 to today. This behavior does not happen automatically, however. The $+=$ operator must be overloaded for this action to occur. In this section, you will learn to overload many of C++'s operators to perform specialized operations on class objects.

NOTE: You have already experienced the behavior of an overloaded operator. The / operator performs two types of division: floating-point and integer. If one of the / operator's operands is a floating-point type, the result will be a floating-point value. If both of the / operator's operands are integers, however, a different behavior occurs: the result is an integer, and any fractional part is thrown away.

## The this Pointer

Before going any further with our discussion of operator overloading, we need to discuss a special pointer named this. The this pointer is a built-in pointer that every class has. It is passed as a hidden argument to all nonstatic member functions, and it always points to the instance of the class making the function call. For example, if student1 and student2 are both StudentTestScores objects, the following statement causes the getStudentName member function to operate on student1:

```
cout << student1.getStudentName() << endl;
```

Likewise, the following statement causes getStudentName to operate on student2:

```
cout << student2.getStudentName() << endl;
```

When getStudentName is operating on student1, the this pointer is pointing to student1. When getStudentName is operating on student2, the this pointer is pointing to student2. The this pointer always points to the object that is being used to call the member function.

## Overloading the $=$ Operator

Although copy constructors solve the initialization problems inherent with objects containing pointer members, they do not work with simple assignment statements. Copy constructors are just that-constructors. They are invoked only when an object is created. Statements like the following still perform memberwise assignment:

```
student2 = student1;
```

In order to change the way the assignment operator works, it must be overloaded. Operator overloading permits you to redefine an existing operator's behavior when used with a class object.

C++ allows a class to have special member functions called operator functions. If you wish to redefine the way a particular operator works with an object, you define a function for that operator. The operator function is then executed any time the operator is used with an object of that class. Let's look at how we might overload the = operator in the StudentTestScores class. If you go to this book's Student Source Code Folder named Chapter 14\StudentTestScores version 3 and open the StudentTestScores.h file, you will find that inside the class, in lines 63 through 74 , we have added the following member function:

```
62 // Overloaded = operator
63 const StudentTestScores operator=(const StudentTestScores &right)
64 { if (this != &right)
65 {
66 delete[] testScores;
67 studentName = right.studentName;
68 numTestScores = right.numTestScores;
                testScores = new double[numTestScores];
                for (int i = 0; i < numTestScores; i++)
                    testScores[i] = right.testScores[i];
    }
    return *this;
}
```

Let's examine the operator function to understand how it works. First, let's dissect the function header, in line 63, into the three parts shown in Figure 14-5.

Figure 14-5 Function header for operator=

- Return type: The function's return type is const StudentTestScores. This means that it returns a StudentTestScores object that is const (it cannot be modified). We will discuss this in greater detail in a moment.
- Function name: The function's name is operator=. This specifies that the function overloads the $=$ operator. Because it is a member of the StudentTestScores class,
this function will be called when an assignment statement executes where the object on the left side of the = operator is a StudentTestScores object.
- Parameter declaration: The function has one parameter: a constant reference object named right. This parameter references the object on the right side of the operator. For example, when the following statement is executed, right will reference the student1 object:

```
student2 = student1;
```

We declared the right parameter as a reference variable for efficiency purposes. This prevents the compiler from making a copy of the object that is being passed into the function. We declared it const, so the function will not accidentally change its contents.

NOTE: In the example, the parameter was named right simply to illustrate that it references the object on the right side of the operator. You can name the parameter anything you wish. It will always take the object on the operator's right as its argument.

In learning the mechanics of operator overloading, it is helpful to know that the following two statements do the same thing:

```
student2 = student1; // Cal1 operator= function
student2.operator=(student1); // Call operator= function
```

In the second statement, you can see exactly what is going on in the function call. The student1 object is being passed to the function's parameter, right. Inside the function, the values in right's members are used to initialize student2. Notice the operator= function has access to the right parameter's private members. Because the operator= function is a member of the StudentTestScores class, it has access to the private members of any StudentTestScores object that is passed into it.

## Checking for Self-Assignment

Recall that this is a hidden argument that is passed to all nonstatic member functions. this is a special pointer that points to the object that called the function. Inside our operator= function, this will point to the object that is on the left side of the $=$ sign, and right will reference the object on the right side of the $=$ sign. This is illustrated in Figure 14-6. In the figure, assume that student1 and student2 are both StudentTestScores objects.

Figure 14-6 The this pointer and the right parameter

Look back at the operator $=$ function, and notice the first statement inside the body of the function (line 64) is an if statement that starts like this:

```
if (this != &right)
```

This if statement is making sure the address stored in this is not the same as the address of the right object. In other words, it is checking for self-assignment. Selfassignment occurs when you assign an object to itself. For example, assume student1 is a StudentTestScores object, and it holds a set of test scores. The following statement performs self-assignment:

```
student1 = student1;
```

Obviously, there is no reason to write a statement like this, but, in programs that work with pointers and references to objects, such assignments can happen in a roundabout way. It is important that you write code in your operator= functions to check for self-assignment, especially in classes that dynamically allocate memory. For example, the following code fragment shows how the operator= member function of the StudentTestScores class would look if we did not check for self-assignment:

```
// Overloaded = operator that does not check for self-assignment
const StudentTestScores operator=(const StudentTestScores &right)
{ de1ete[] testScores;
    studentName = right.studentName;
    numTestScores = right.numTestScores;
    testScores = new double[numTestScores];
    for (int i = 0; i < numTestScores; i++)
        testScores[i] = right.testScores[i];
    return *this;
}
```

In this version of the function, the first thing we do is delete the memory for the testScores array. In the event of self-assignment, this will be a problem because we are deleting the memory from which we will be copying! Obviously, the assignment will not work as intended. The corrected version of the function, shown again here, avoids the problem by skipping all of the assignment steps when self-assignment has been detected:

```
// Overloaded = operator
const StudentTestScores operator=(const StudentTestScores &right)
{ if (this != &right)
    {
        delete[] testScores;
        studentName = right.studentName;
        numTestScores = right.numTestScores;
        testScores = new double[numTestScores];
        for (int i = 0; i < numTestScores; i++)
            testScores[i] = right.testScores[i];
        }
        return *this;
    }
```

## The = Operator's Return Value

The last thing we need to discuss about the operator= function is its return value. Recall that C++'s built-in = operator allows multiple assignment statements such as:

$$
a=b=c=d ;
$$

This statement works in the following way:

- The expression $c=d$ assigns $d$ to $c$, then returns the new value of $c$.
- The new value of $c$, which is returned from the previous expression is assigned to $b$, then the new value of $b$ is returned.
- The new value of $b$, which is returned from the previous expression, is assigned to $a$.

If a class object's overloaded $=$ operator is to function this way, it too must return the value of the object that received the assignment. That's why the operator= function in the StudentTestScores class has a return type of const StudentTestScores, and the last statement in the function is:

```
return *this;
```

The expression *this dereferences the this pointer, giving us the actual object that received the assignment. A const copy of that object is then returned.

## Copy Assignment

The overloaded = operator that we just looked at is an example of a copy assignment operator. It is called a copy assignment operator because it copies data from one object to another. Later in this chapter, you will see an example of another type of assignment known as move assignment.
Program 14-6 demonstrates the StudentTestScores class with its overloaded assignment operator. (This file can be found in the Student Source Code Folder Chapter 14\} StudentTestScores Version 3.)

## Program 14-6

```
// This program demonstrates the overloaded = operator
#include <iostream>
#include "StudentTestScores.h"
using namespace std;
// Function prototype
void displayStudent(StudentTestScores);
int main()
{
    // Create a StudentTestScores object and
    // assign test scores.
    StudentTestScores student1("Kel1y Thorton", 3);
    student1.setTestScore(100.0, 0);
    student1.setTestScore(95.0, 1);
    student1.setTestScore(80, 2);
    // Create another StudentTestScore object
    // with default test scores.
    StudentTestScores student2("Jimmy Griffin", 5);
    // Assign the student1 object to student2
    student2 = student1;
```

## Program 14-6 (continued)

```
    // Display both objects. They should
    // contain the same data.
    disp1ayStudent(student1);
    disp1ayStudent(student2);
    return 0;
}
// The displayStudent function accepts a
// StudentTestScores object's data.
void displayStudent(StudentTestScores s)
{
    cout << "Name: " << s.getStudentName() << endl;
    cout << "Test Scores: ";
    for (int i = 0; i < s.getNumTestScores(); i++)
        cout << s.getTestScore(i) << " ";
        cout << endl;
}
```

## Program Output

Name: Kelly Thorton
Test Scores: 1009580
Name: Kelly Thorton
Test Scores: 1009580

The overloaded $=$ operator function is demonstrated again in Program 14-7. The multiple assignment statement in line 22 causes the operator= function to execute. (This file and the revised version of the StudentTestScores class can be found in the Student Source Code Folder Chapter 14\StudentTestScores Version 4.)

## Program 14-7

```
// This program demonstrates the overloaded = operator returning a value.
#include <iostream>
#include "StudentTestScores.h"
using namespace std;
// Function prototype
void displayStudent(StudentTestScores);
int main()
{
    // Create a StudentTestScores object.
    StudentTestScores student1("Kelly Thorton", 3);
    student1.setTestScore(100.0, 0);
    student1.setTestScore(95.0, 1);
    student1.setTestScore(80, 2);
    // Create two more StudentTestScores objects.
    StudentTestScores student2("Jimmy Griffin", 5);
    StudentTestScores student3("Kristen Lee", 10);
```

```
    // Assign student1 to student2 and student3.
    student3 = student2 = student1;
    // Display the objects.
    displayStudent(student1);
    displayStudent(student2);
    displayStudent(student3);
    return 0;
}
// displayStudent function
void displayStudent(StudentTestScores s)
{
    cout << "Name: " << s.getStudentName() << endl;
    cout << "Test Scores: ";
    for (int i = 0; i < s.getNumTestScores(); i++)
        cout << s.getTestScore(i) << " ";
    cout << endl;
}
```

## Program Output

Name: Kelly Thorton
Test Scores: 1009580
Name: Kelly Thorton
Test Scores: 1009580
Name: Kelly Thorton
Test Scores: 1009580

## Some General Issues of Operator Overloading

Now that you have had a taste of operator overloading, let's look at some of the general issues involved in this programming technique.

Although it is not a good programming practice, you can change an operator's entire meaning if that's what you wish to do. There is nothing to prevent you from changing the $=$ symbol from an assignment operator to a "display" operator. For instance, the following class does just that:

```
class Weird
{
private:
    int value;
public:
    Weird(int v)
        { value = v; }
    void operator=(const weird &right) const
        { cout << right.value << endl; }
};
```

Although the operator= function in the Weird class overloads the assignment operator, the function doesn't perform an assignment. Instead, it displays the contents of right.value. Consider the following program segment:

```
Weird a(5), b(10);
a = b;
```

Although the statement $\mathrm{a}=\mathrm{b}$ looks like an assignment statement, it actually causes the contents of b's value member to be displayed on the screen:

10
Another operator overloading issue is you cannot change the number of operands taken by an operator. The = symbol must always be a binary operator. Likewise, ++ and -- must always be unary operators.

The last issue is although you may overload most of the C++ operators, you cannot overload all of them. Table 14-1 shows all of the C++ operators that may be overloaded (some of the operators shown in the table are beyond the scope of this book and are not discussed).

Table 14-1 Operators that May Be Overloaded

| + | - | $*$ | $\mid$ | $\%$ | $\wedge$ | $\&$ | $\mid$ | $\sim$ | $!$ | $=$ | $<$ |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| $>$ | $+=$ | $-=$ | $*=$ | $I=$ | $\%=$ | $\wedge=$ | $\&=$ | $\mid=$ | $\ll$ | $\gg$ | $\gg=$ |
| $\ll=$ | $==$ | $!=$ | $<=$ | $>=$ | $\& \&$ | $\|\mid$ | ++ | -- | $-<*$ | , | $-<$ |
| [] | () | new | delete |  |  |  |  |  |  |  |  |

The only operators that cannot be overloaded are
?: . .* : $\quad$ sizeof

## Overloading Math Operators

Many classes would benefit not only from an overloaded assignment operator, but also from overloaded math operators. To illustrate this, consider the Feet Inches class shown in the following two files. (These files can be found in the Student Source Code Folder Chapter 14\FeetInches Version 1.)

## Contents of Feet Inches.h (Version 1)

```
#ifndef FEETINCHES_H
#define FEETINCHES_H
// The FeetInches class holds distances or measurements
// expressed in feet and inches.
class FeetInches
{
private:
    int feet; // To hold a number of feet
    int inches; // To hold a number of inches
    void simplify(); /l Defined in FeetInches.cpp
public:
    // Constructor
    FeetInches(int f = 0, int i = 0)
            { feet = f;
                inches = i;
                simplify(); }
```

```
    // Mutator functions
    void setFeet(int f)
        { feet = f; }
    void setInches(int i)
        { inches = i;
        simplify(); }
    // Accessor functions
    int getFeet() const
        { return feet; }
    int getInches() const
        { return inches; }
    // Overloaded operator functions
    FeetInches operator + (const FeetInches &); // Overloaded +
    FeetInches operator - (const FeetInches &); // Overloaded -
};
#endif
```

## Contents of Feet Inches. cpp (Version 1)

```
// Implementation file for the FeetInches class
#include <cstdlib> // Needed for abs()
#include "FeetInches.h"
//**************************************************************
// Definition of member function simplify. This function *
// checks for values in the inches member greater than *
// twelve or less than zero. If such a value is found, *
// the numbers in feet and inches are adjusted to conform *
// to a standard feet & inches expression. For example, *
// 3 feet 14 inches would be adjusted to 4 feet 2 inches and *
// 5 feet -2 inches would be adjusted to 4 feet 10 inches.
//*******************************************************************
void FeetInches::simplify()
{
    if (inches >= 12)
    {
        feet += (inches / 12);
        inches = inches % 12;
    }
    else if (inches < O)
    {
        feet -= ((abs(inches) / 12) + 1);
        inches = 12 - (abs(inches) % 12);
    }
}
```

```
//************************************************
// Overloaded binary + operator.
//*************************************************
FeetInches FeetInches::operator + (const FeetInches &right)
{
    FeetInches temp;
        temp.inches = inches + right.inches;
        temp.feet = feet + right.feet;
        temp.simplify();
        return temp;
}
//*************************************************
// Overloaded binary - operator.
//***********************************************
FeetInches FeetInches::operator - (const FeetInches &right)
{
    FeetInches temp;
    temp.inches = inches - right.inches;
    temp.feet = feet - right.feet;
    temp.simp1ify();
    return temp;
}
```

The Feet Inches class is designed to hold distances or measurements expressed in feet and inches. It consists of eight member functions:

- A constructor that allows the feet and inches members to be set. The default values for these members is zero.
- setFeet-a function for storing a value in the feet member
- setInches-a function for storing a value in the inches member
- getFeet-a function for returning the value in the feet member
- getInches-a function for returning the value in the inches member
- simplify-a function for normalizing the values held in feet and inches. This function adjusts any set of values where the inches member is greater than 12 or less than 0 .
- operator + -a function that overloads the standard + math operator
- operator -—a function that overloads the standard - math operator

NOTE: The simplify function uses the standard library function abs() to get the absolute value of the inches member. The abs() function requires that cstdlib be included.

The overloaded + and - operators allow one Feet Inches object to be added to or subtracted from another. For example, assume the length1 and 1ength2 objects are defined and initialized as follows:

```
FeetInches length1(3, 5), length2(6, 3);
```

The length 1 object is holding the value 3 feet 5 inches, and the length 2 object is holding the value 6 feet 3 inches. Because the + operator is overloaded, we can add these two objects in a statement such as:

```
1ength3 = 1ength1 + 1ength2;
```

This statement will add the values of the 1ength1 and 1ength2 objects and store the result in the length 3 object. After the statement executes, the length 3 object will be set to 9 feet 8 inches.

The member function that overloads the + operator appears in lines 33 through 41 of the FeetInches.cpp file.

This function is called anytime the + operator is used with two Feet Inches objects. Just like the overloaded = operator we defined in the previous section, this function has one parameter: a constant reference object named right. This parameter references the object on the right side of the operator. For example, when the following statement is executed, right will reference the length2 object:

```
1ength3 = 1ength1 + 1ength2;
```

As before, it might be helpful to think of the statement above as the following function call:

```
1ength3 = 1ength1.operator+(1ength2);
```

The length2 object is being passed to the function's parameter, right. When the function finishes, it will return a Feet Inches object to length3. Now let's see what is happening inside the function. First, notice a Feet Inches object named temp is defined locally in line 35:

```
FeetInches temp;
```

This object is a temporary location for holding the results of the addition. Next, line 37 adds inches to right.inches and stores the result in temp.inches:

```
temp.inches = inches + right.inches;
```

The inches variable is a member of length1, the object making the function call. It is the object on the left side of the operator. right.inches references the inches member of 1ength2. The next statement, in line 38 , is very similar. It adds feet to right.feet and stores the result in temp. feet.

```
temp.feet = feet + right.feet;
```

At this point in the function, temp contains the sum of the feet and inches members of both objects in the expression. The next step is to adjust the values, so they conform to a normal value expressed in feet and inches. This is accomplished in line 39 by calling temp. simplify ():

```
temp.simp1ify();
```

The last step, in line 40, is to return the value stored in temp:
return temp;
In the statement length $3=1$ ength $1+$ length 2 , the return statement in the operator function causes the values stored in temp to be returned to the length3 object.

Program 14-8 demonstrates the overloaded operators. (This file can be found in the Student Source Code Folder Chapter 14\FeetInches Version 1.)

## Program 14-8

```
// This program demonstrates the FeetInches class's overloaded
// + and - operators.
#include <iostream>
#include "FeetInches.h"
using namespace std;
int main()
{
    int feet, inches; // To hold input for feet and inches
    // Create three FeetInches objects. The default arguments
    // for the constructor will be used.
    FeetInches first, second, third;
    // Get a distance from the user.
    cout << "Enter a distance in feet and inches: ";
    cin >> feet >> inches;
    // Store the distance in the first object.
    first.setFeet(feet);
    first.setInches(inches);
    // Get another distance from the user.
    cout << "Enter another distance in feet and inches: ";
    cin >> feet >> inches;
    // Store the distance in second.
    second.setFeet(feet);
    second.setInches(inches);
    // Assign first + second to third.
    third = first + second;
    // Display the result.
    cout << "first + second = ";
    cout << third.getFeet() << " feet, ";
    cout << third.getInches() << " inches.\n";
    // Assign first - second to third.
    third = first - second;
    // Display the result.
    cout << "first - second = ";
    cout << third.getFeet() << " feet, ";
    cout << third.getInches() << " inches.\n";
    return 0;
}
```

## Program Output with Example Input Shown in Bold

```
Enter a distance in feet and inches: 65 Enter
Enter another distance in feet and inches: 310 Enter
first + second = 10 feet, 3 inches.
first - second = 2 feet, 7 inches.
```

## Overloading the Prefix ++ Operator

Unary operators, such as ++ and --, are overloaded in a fashion similar to the way binary operators are implemented. Because unary operators only affect the object making the operator function call, however, there is no need for a parameter. For example, let's say you wish to have a prefix increment operator for the Feet Inches class. Assume the Feet Inches object distance is set to the values 7 feet and 5 inches. A ++ operator function could be designed to increment the object's inches member. The following statement would cause distance to have the value 7 feet 6 inches:

```
++distance;
```

The following function overloads the prefix ++ operator to work in this fashion:

```
FeetInches FeetInches::operator++()
{
    ++inches;
    simplify();
    return *this;
}
```

This function first increments the object's inches member. The simplify() function is called then the dereferenced this pointer is returned. This allows the operator to perform properly in statements like this:

```
distance2 = ++distance1;
```

Remember, the statement above is equivalent to

```
distance2 = distance1.operator++();
```

## Overloading the Postfix ++ Operator

Overloading the postfix ++ operator is only slightly different than overloading the prefix version. Here is the function that overloads the postfix operator with the Feet Inches class:

```
FeetInches FeetInches::operator++(int)
{
    FeetInches temp(feet, inches);
    inches++;
    simplify();
    return temp;
}
```

The first difference you will notice is the use of a dummy parameter. The word int in the function's parentheses establishes a nameless integer parameter. When C++ sees this parameter in an operator function, it knows the function is designed to be used in postfix mode. The second difference is the use of a temporary local variable, the temp object. temp is initialized with the feet and inches values of the object making the function call. temp,
therefore, is a copy of the object being incremented, but before the increment takes place. After inches is incremented and the simplify function is called, the contents of temp is returned. This causes the postfix operator to behave correctly in a statement like this:

```
distance2 = distance1++;
```

You will find a version of the FeetInches class with the overloaded prefix and postfix ++ operators in the Student Source Code Folder Chapter 14\FeetInches Version 2. In that folder, you will also find Program 14-9, which demonstrates these overloaded operators.

## Program 14-9

```
// This program demonstrates the FeetInches class's overloaded
// prefix and postfix ++ operators.
#include <iostream>
#include "FeetInches.h"
using namespace std;
int main()
{
    int count; // Loop counter
    // Define a FeetInches object with the default
    // value of 0 feet, O inches.
    FeetInches first;
    // Define a FeetInches object with 1 foot 5 inches.
    FeetInches second(1, 5);
    // Use the prefix ++ operator.
    cout << "Demonstrating prefix ++ operator.\n";
    for (count = 0; count < 12; count++)
    {
        first = ++second;
        cout << "first: " << first.getFeet() << " feet, ";
        cout << first.getInches() << " inches. ";
        cout << "second: " << second.getFeet() << " feet, ";
        cout << second.getInches() << " inches.\n";
    }
    // Use the postfix ++ operator.
    cout << "\nDemonstrating postfix ++ operator.\n";
    for (count = 0; count < 12; count++)
    {
        first = second++;
        cout << "first: " << first.getFeet() << " feet, ";
        cout << first.getInches() << " inches. ";
        cout << "second: " << second.getFeet() << " feet, ";
        cout << second.getInches() << " inches.\n";
    }
    return 0;
}
```

```
Program Output

## (1) Checkpoint

14.14 Assume there is a class named Pet. Write the prototype for a member function of Pet that overloads the = operator.
14.15 Assume dog and cat are instances of the Pet class, which has overloaded the = operator. Rewrite the following statement so it appears in function call notation instead of operator notation:
dog = cat;
14.16 What is the disadvantage of an overloaded = operator returning void?
14.17 Describe the purpose of the this pointer.
14.18 The this pointer is automatically passed to what type of functions?
14.19 Assume there is a class named Animal that overloads the $=$ and + operators. In the following statement, assume cat, tiger, and wildcat are all instances of the Animal class:
wildcat = cat + tiger;
Of the three objects, wildcat, cat, or tiger, which is calling the operator+ function? Which object is passed as an argument into the function?
14.20 What does the use of a dummy parameter in a unary operator function indicate to the compiler?

## Overloading Relational Operators

In addition to the assignment and math operators, relational operators may be overloaded. This capability allows classes to be compared in statements that use relational expressions such as:

```
if (distance1 < distance2)
{
    ... code ...
}
```

Overloaded relational operators are implemented like other binary operators. The only difference is that a relational operator function should always return a true or false value. The FeetInches class in the Student Source Code Folder Chapter 14|FeetInches Version 3 contains functions to overload the $>$, <, and $==$ relational operators. Here is the function for overloading the > operator:

```
bool FeetInches::operator > (const FeetInches &right)
{
    bool status;
    if (feet > right.feet)
        status = true;
    else if (feet == right.feet && inches > right.inches)
        status = true;
    e1se
        status = false;
        return status;
}
```

As you can see, the function compares the feet member (and if necessary, the inches member) with that of the parameter. If the calling object contains a value greater than that of the parameter, true is returned. Otherwise, false is returned.

Here is the code that overloads the < operator:

```
bool FeetInches::operator < (const FeetInches &right)
{
    bool status;
    if (feet < right.feet)
        status = true;
    else if (feet == right.feet && inches < right.inches)
        status = true;
    else
        status = false;
    return status;
}
```

Here is the code that overloads the $==$ operator:

```
boo1 FeetInches::operator == (const FeetInches &right)
{
    bool status;
    if (feet == right.feet && inches == right.inches)
        status = true;
    else
        status = false;
```

```
    return status;
}
```

Program 14-10 demonstrates these overloaded operators. (This file can also be found in the Student Source Code Folder Chapter 14\FeetInches Version 3.)

## Program 14-10

```
// This program demonstrates the FeetInches class's overloaded
// relational operators.
#include <iostream>
#include "FeetInches.h"
using namespace std;
int main()
{
    int feet, inches; // To hold input for feet and inches
    // Create two FeetInches objects. The default arguments
    // for the constructor will be used.
    FeetInches first, second;
    // Get a distance from the user.
    cout << "Enter a distance in feet and inches: ";
    cin >> feet >> inches;
    // Store the distance in first.
    first.setFeet(feet);
    first.setInches(inches);
    // Get another distance.
    cout << "Enter another distance in feet and inches: ";
    cin >> feet >> inches;
    // Store the distance in second.
    second.setFeet(feet);
    second.setInches(inches);
    // Compare the two objects.
    if (first == second)
        cout << "first is equal to second.\n";
    if (first > second)
        cout << "first is greater than second.\n";
    if (first < second)
        cout << "first is less than second.\n";
    return 0;
}
```

## Program Output with Example Input Shown in Bold

Enter a distance in feet and inches: 65 Enter
Enter another distance in feet and inches: 310 Enter
first is greater than second.

```
Program 14-10 (continued)
Program Output with Different Example Input Shown in Bold
Enter a distance in feet and inches: 55 Enter
Enter another distance in feet and inches: 55 Enter
first is equal to second.
```

## Program Output with Different Example Input Shown in Bold

```
Enter a distance in feet and inches: 34 Enter
Enter another distance in feet and inches: 37 Enter
first is less than second.
```

## Overloading the << and >> Operators

Overloading the math and relational operators gives you the ability to write those types of expressions with class objects just as naturally as with integers, floats, and other built-in data types. If an object's primary data members are private, however, you still have to make explicit member function calls to send their values to cout. For example, assume distance is a FeetInches object. The following statements display its internal values:

```
cout << distance.getFeet() << " feet, ";
cout << distance.getInches() << "inches";
```

It is also necessary to explicitly call member functions to set a FeetInches object's data. For instance, the following statements set the distance object to user-specified values:

```
cout << "Enter a value in feet: ";
cin >> f;
distance.setFeet(f);
cout << "Enter a value in inches: ";
cin >> i;
distance.setInches(i);
```

By overloading the stream insertion operator (<<), you could send the distance object to cout, as shown in the following code, and have the screen output automatically formatted in the correct way:

```
cout << distance;
```

Likewise, by overloading the stream extraction operator (>>), the distance object could take values directly from cin, as shown here:

```
cin >> distance;
```

Overloading these operators is done in a slightly different way, however, than overloading other operators. These operators are actually part of the ostream and istream classes defined in the C++ runtime library. (The cout and cin objects are instances of ostream and istream.) You must write operator functions to overload the ostream version of << and the istream version of >>, so they work directly with a class such as FeetInches. The FeetInches class in the Student Source Code Folder Chapter 14\FeetInches Version 4 contains functions to overload the << and >> operators. Here is the function that overloads the << operator:

```
ostream &operator << (ostream &strm, const FeetInches &obj)
{
    strm << obj.feet << " feet, " << obj.inches << " inches";
    return strm;
}
```

Notice the function has two parameters: an ostream reference object and a const FeetInches reference object. The ostream parameter will be a reference to the actual ostream object on the left side of the << operator. The second parameter is a reference to a FeetInches object. This parameter will reference the object on the right side of the << operator. This function tells C++ how to handle any expression that has the following form:

```
ostreamObject << FeetInchesObject
```

So, when C++ encounters the following statement, it will call the overloaded operator<< function:

```
cout << distance;
```

Notice the function's return type is ostream \&. This means the function returns a reference to an ostream object. When the return strm; statement executes, it doesn't return a copy of strm, but a reference to it. This allows you to chain together several expressions using the overloaded << operator, such as:

```
cout << distance1 << " " << distance2 << endl;
```

Here is the function that overloads the stream extraction operator to work with the Feet Inches class:

```
istream &operator >> (istream &strm, FeetInches &obj)
{
    // Prompt the user for the feet.
    cout << "Feet: ";
    strm >> obj.feet;
    // Prompt the user for the inches.
    cout << "Inches: ";
    strm >> obj.inches;
    // Normalize the values.
    obj.simplify();
    return strm;
}
```

The same principles hold true for this operator. It tells C++ how to handle any expression in the following form:

```
istreamObject >> FeetInchesObject
```

Once again, the function returns a reference to an istream object, so several of these expressions may be chained together.

You have probably realized that neither of these functions is quite ready to work, though. Both functions attempt to directly access the Feet Inches object's private members. Because the functions aren't themselves members of the Feet Inches class, they don't have this type of access. The next step is to make the operator functions friends of FeetInches. This is
shown in the following listing of the FeetInches class declaration. (This file can be found in the Student Source Code Folder Chapter 14\FeetInches Version 4.)

NOTE: Some compilers require you to prototype the >> and << operator functions outside the class. For this reason, we have added the following statements to the FeetInches.h class specification file.

```
class FeetInches; // Forward Declaration
// Function Prototypes for Overloaded Stream Operators
ostream &operator << (ostream &, const FeetInches &);
istream &operator >> (istream &, FeetInches &);
```

## Contents of Feet Inches.h (Version 4)

```
#ifndef FEETINCHES_H
#define FEETINCHES_H
#include <iostream>
using namespace std;
class FeetInches; // Forward Declaration
// Function Prototypes for Overloaded Stream Operators
ostream &operator << (ostream &, const FeetInches &);
istream &operator >> (istream &, FeetInches &);
// The FeetInches class holds distances or measurements
// expressed in feet and inches.
class FeetInches
{
private:
    int feet; // To hold a number of feet
    int inches; // To hold a number of inches
    void simplify(); // Defined in FeetInches.cpp
public:
    // Constructor
    FeetInches(int f = 0, int i = 0)
            { feet = f;
            inches = i;
            simplify(); }
    // Mutator functions
    void setFeet(int f)
        { feet = f; }
    void setInches(int i)
        { inches = i;
                simplify(); }
    // Accessor functions
```

```
    int getFeet() const
    { return feet; }
        int getInches() const
        { return inches; }
        // Overloaded operator functions
        FeetInches operator + (const FeetInches &); // Overloaded +
        FeetInches operator - (const FeetInches &); // Overloaded -
        FeetInches operator ++ (); // Prefix ++
        FeetInches operator ++ (int); // Postfix ++
        bool operator > (const FeetInches &); /l Overloaded >
        bool operator < (const FeetInches &); // Overloaded <
        bool operator == (const FeetInches &); // Overloaded ==
        // Friends
        friend ostream &operator << (ostream &, const FeetInches &);
        friend istream &operator >> (istream &, FeetInches &);
};
#endif
```

Lines 54 and 55 in the class declaration tell C++ to make the overloaded << and >> operator functions friends of the Feet Inches class:
friend ostream \&operator<<(ostream \&, const FeetInches \&); friend istream \&operator>>(istream \& , FeetInches \&);

These statements give the operator functions direct access to the Feet Inches class's private members. Program 14-11 demonstrates how the overloaded operators work. (This file can also be found in the Student Source Code Folder Chapter 14\FeetInches Version 4.)

## Program 14-11

```
// This program demonstrates the << and >> operators,
// overloaded to work with the FeetInches class.
#include <iostream>
#include "FeetInches.h"
using namespace std;
int main()
{
    FeetInches first, second; // Define two objects.
    // Get a distance for the first object.
    cout << "Enter a distance in feet and inches.\n";
    cin >> first;
    // Get a distance for the second object.
    cout << "Enter another distance in feet and inches.\n";
    cin >> second;
    // Display the values in the objects.
    cout << "The values you entered are:\n";
```

## Program 14-11 (continued)

```
21 cout << first << " and " << second << endl;
22 return 0;
23 }
```

## Program Output with Example Input Shown in Bold

Enter a distance in feet and inches.
Feet: 6 Enter
Inches: 5 Enter
Enter another distance in feet and inches.
Feet: 3 Enter
Inches: 10 Enter
The values you entered are:
6 feet, 5 inches and 3 feet, 10 inches

## Overloading the [ ] Operator

In addition to the traditional operators, C++ allows you to change the way the [] symbols work. This gives you the ability to write classes that have array-like behaviors. For example, the string class overloads the [] operator, so you can access the individual characters stored in string class objects. Assume the following definition exists in a program:

```
string name = "William";
```

The first character in the string, 'W,' is stored at name [0], so the following statement will display W on the screen.

```
cout << name[0];
```

You can use the overloaded [] operator to create an array class, like the following one. The class behaves like a regular array, but performs the bounds checking that C++ lacks.

## Contents of IntArray.h

```
// Specification file for the IntArray class
#ifndef INTARRAY_H
#define INTARRAY_H
class IntArray
{
private:
    int *aptr; // Pointer to the array
    intarraySize; /l Holds the array size
    void subscriptError(); // Handles invalid subscripts
public:
    IntArray(int); // Constructor
    IntArray(const IntArray &); // Copy constructor
    ~IntArray(); // Destructor
    int size() const // Returns the array size
        { return arraySize; }
    const IntArray operator=(const IntArray &); // Overloaded = operator
    int &operator[](const int &); // Overloaded [] operator
};
#endif
```

## Contents of IntArray.cpp

```
// Implementation file for the IntArray class
#include <iostream>
#include <cstdlib> // For the exit function
#include "IntArray.h"
using namespace std;
/l*********************************************************
// Constructor for IntArray class. Sets the size of the *
// array and allocates memory for it.
//***********************************************************

IntArray::~IntArray()
{
    if (arraySize > 0)
        delete [] aptr;
}
//**************************************************************
// terminates the program when a subscript is out of range.
//*************************************************************
void IntArray::subscriptError()
{
    cout << "ERROR: Subscript out of range.\n";
    exit(0);
}
//**********************************************************
// Overloaded = operator
|/*********************************************************
const IntArray IntArray::operator=(const IntArray &right)
```

```
{
    if (this != &right)
    {
        delete[] aptr;
        arraySize = right.arraySize;
        aptr = new int[arraySize];
        for (int count = 0; count < arraySize; count++)
            *(aptr + count) = *(right.aptr + count);
    }
    return *this;
}
//*********************************************************
// Overloaded [] operator. The argument is a subscript.
// This function returns a reference to the element
// in the array indexed by the subscript.
//**********************************************************
int &IntArray::operator[](const int &sub)
{
    if (sub < 0 || sub >= arraySize)
        subscriptError();
    return aptr[sub];
}
```

Before focusing on the overloaded [] operator, let's look at the constructors and the destructor. The code for the first constructor in lines 11 through 17 of the IntArray.cpp file follows:

```
IntArray::IntArray(int s)
{
    arraySize = s;
    aptr = new int [s];
    for (int count = 0; count < arraySize; count++)
        *(aptr + count) = 0;
}
```

When an instance of the class is defined, the required number of elements is passed into the constructor's parameter, s. This value is assigned to the arraySize member, then used to dynamically allocate enough memory for the array. The constructor's final step is to store zeros in all of the array's elements.

The class also has a copy constructor in lines 22 through 28 which is used when a class object is initialized with another object's data:

```
IntArray::IntArray(const IntArray &obj)
{
    arraySize = obj.arraySize;
    aptr = new int [arraySize];
    for(int count = 0; count < arraySize; count++)
    *(aptr + count) = *(obj.aptr + count);
}
```

A reference to the initializing object is passed into the parameter obj. Once the memory is successfully allocated for the array, the constructor copies all the values in obj's array into the calling object's array.

The destructor, in lines 33 through 37, simply frees the memory allocated by the class's constructors. First, however, it checks the value in arraySize to be sure the array has at least one element:

```
IntArray::~IntArray()
{
    if (arraySize > 0)
        delete [] aptr;
}
```

The [] operator is overloaded similarly to other operators. The definition of the operator [] function appears in lines 70 through 75:

```
int &IntArray::operator[](const int &sub)
{
    if (sub < 0 || sub >= arraySize)
        subscriptError();
    return aptr[sub];
}
```

The operator [] function can have only a single parameter. The one shown uses a constant reference to an integer. This parameter holds the value placed inside the brackets in an expression. For example, if table is an IntArray object, the number 12 will be passed into the sub parameter in the following statement:

```
cout << table[12];
```

Inside the function, the value in the sub parameter is tested by the following if statement:

```
if (sub < 0 || sub >= arraySize)
    subscriptError();
```

This statement determines whether sub is within the range of the array's subscripts. If sub is less than 0 , or greater than or equal to arraySize, it's not a valid subscript, so the subscriptError function is called. If sub is within range, the function uses it as an offset into the array and returns a reference to the value stored at that location.
One critically important aspect of the function above is its return type. It's crucial that the function return not simply an integer, but a reference to an integer. The reason for this is that expressions such as the following must be possible:

```
table[5] = 27;
```

Remember, the built-in = operator requires the object on its left to be an lvalue. An lvalue must represent a modifiable memory location, such as a variable. The integer return value of a function is not an lvalue. If the operator [] function merely returns an integer, it cannot be used to create expressions placed on the left side of an assignment operator.
A reference to an integer, however, is an lvalue. If the operator [] function returns a reference, it can be used to create expressions like the following:

```
table[7] = 52;
```

In this statement, the operator [ ] function is called with 7 passed as its argument. Assuming 7 is within range, the function returns a reference to the integer stored at (aptr+7 ). In essence, the statement above is equivalent to:

```
*(aptr + 7) = 52;
```

Because the operator [] function returns actual integers stored in the array, it is not necessary for math or relational operators to be overloaded. Even the stream operators $\ll$ and >> will work just as they are with the IntArray class.

Program 14-12 demonstrates how the class works.

## Program 14-12

```
// This program demonstrates an overloaded [] operator.
#include <iostream>
#include "IntArray.h"
using namespace std;
int main()
{
    const int SIZE = 10; // Array size
    // Define an IntArray with 10 elements.
    IntArray table(SIZE);
    // Store values in the array.
    for (int x = 0; x < SIZE; x++)
        table[x] = (x * 2);
    // Display the values in the array.
    for (int x = 0; x < SIZE; x++)
        cout << table[x] << " ";
    cout << endl;
    // Use the standard + operator on array elements.
    for (int x = 0; x < SIZE; x++)
        table[x] = table[x] + 5;
    // Display the values in the array.
    for (int x = 0; x < SIZE; x++)
        cout << table[x] << " ";
    cout << endl;
    // Use the standard ++ operator on array elements.
    for (int x = 0; x < SIZE; x++)
        table[x]++;
    // Display the values in the array.
    for (int x = 0; x < SIZE; x++)
        cout << table[x] << " ";
    cout << endl;
    return 0;
}
```

## Program Output

024681012141618
$\begin{array}{lllllllll}5 & 7 & 9 & 11 & 13 & 15 & 17 & 21 & 23\end{array}$
681012141618202224
Program 14-13 demonstrates the IntArray class's bounds-checking capability.

## Program 14-13

```
// This program demonstrates the IntArray class's bounds-checking ability.
#include <iostream>
#include "IntArray.h"
using namespace std;
int main()
{
        const int SIZE = 10; // Array size
        // Define an IntArray with 10 elements.
        IntArray table(SIZE);
        // Store values in the array.
        for (int x = 0; x < SIZE; x++)
            table[x] = x;
        // Display the values in the array.
        for (int x = 0; x < SIZE; x++)
            cout << table[x] << " ";
        cout << endl;
        // Attempt to use an invalid subscript.
        cout << "Now attempting to use an invalid subscript.\n";
        table[SIZE + 1] = 0;
        return 0;
}
```

## Program Output

0123456789
Now attempting to use an invalid subscript.
ERROR: Subscript out of range.

## Checkpoint

14.21 Describe the values that should be returned from functions that overload relational operators.
14.22 What is the advantage of overloading the << and >> operators?
14.23 What type of object should an overloaded $\ll$ operator function return?
14.24 What type of object should an overloaded $\gg$ operator function return?
14.25 If an overloaded << or >> operator accesses a private member of a class, what must be done in that class's declaration?
14.26 Assume the class NumList has overloaded the [] operator. In the expression below, list1 is an instance of the NumList class:
1ist1[25]
Rewrite the expression above to explicitly call the function that overloads the [] operator.

### 14.6 Object Conversion

CONCEPT: Special operator functions may be written to convert a class object to any other type.

As you've already seen, operator functions allow classes to work more like built-in data types. Another capability that operator functions can give classes is automatic type conversion.

Data type conversion happens "behind the scenes" with the built-in data types. For instance, suppose a program uses the following variables:

```
int i;
double d;
```

The statement below automatically converts the value in $i$ to a floating-point number and stores it in d:

$$
d=i ;
$$

Likewise, the following statement converts the value in $d$ to an integer (truncating the fractional part) and stores it in i :

$$
\mathrm{i}=\mathrm{d} ;
$$

The same functionality can also be given to class objects. For example, assuming distance is a FeetInches object and d is a double, the following statement would conveniently convert distance's value into a floating-point number and store it in d, if FeetInches is properly written:

```
d = distance;
```

To be able to use a statement such as this, an operator function must be written to perform the conversion. The Student Source Code Folder Chapter 14\FeetInches Version 5 contains a version of the FeetInches class with such an operator function. Here is the code for the operator function that converts a FeetInches object to a double:

```
FeetInches::operator double()
{
    double temp = feet;
    temp += (inches / 12.0);
    return temp;
}
```

This function contains an algorithm that will calculate the decimal equivalent of a feet and inches measurement. For example, the value 4 feet 6 inches will be converted to 4.5 . This value is stored in the local variable temp. The temp variable is then returned.

NOTE: No return type is specified in the function header. Because the function is a FeetInches-to-double conversion function, it will always return a double. Also, because the function takes no arguments, there are no parameters.

The revised FeetInches class also has an operator function that converts a FeetInches object to an int. The function, shown here, simply returns the feet member, thus truncating the inches value:

```
FeetInches:: operator int()
{
    return feet;
}
```

Program 14-14 demonstrates both of these conversion functions. (This file can also be found in the Student Source Code Folder Chapter 14\FeetInches Version 5.)

## Program 14-14

```
// This program demonstrates the FeetInches class's
// conversion functions.
#include <iostream>
#include "FeetInches.h"
using namespace std;
int main()
{
    double d; // To hold double input
    int i; // To hold int input
    // Define a FeetInches object.
    FeetInches distance;
    // Get a distance from the user.
    cout << "Enter a distance in feet and inches:\n";
    cin >> distance;
    // Convert the distance object to a double.
    d = distance;
    // Convert the distance object to an int.
    i = distance;
    // Display the values.
    cout << "The value " << distance;
    cout << " is equivalent to " << d << " feet\n";
    cout << "or " << i << " feet, rounded down.ln";
    return 0;
}
```

## Program Output with Example Input Shown in Bold

Enter a distance in feet and inches:
Feet: 8 Enter
Inches: 6 Enter
The value 8 feet, 6 inches is equivalent to 8.5 feet or 8 feet, rounded down.

See the Case Study on Creating a String Class for another example. You can download the case study from the Computer Science Portal at www.pearsonglobaleditions.com/gaddis.

## Checkpoint

14.27 When overloading a binary operator such as + or -, what object is passed into the operator function's parameter?
14.28 Explain why overloaded prefix and postfix ++ and -- operator functions should return a value.
14.29 How does C++ tell the difference between an overloaded prefix and postfix ++ or -- operator function?
14.30 Write member functions of the FeetInches class that overload the prefix and postfix -- operators. Demonstrate the functions in a simple program similar to Program 14-14.

### 14.7 Aggregation

CONCEPT: Aggregation occurs when a class contains an instance of another class.

In real life, objects are frequently made of other objects. A house, for example, is made of door objects, window objects, wall objects, and much more. It is the combination of all these objects that makes a house object.
When designing software, it sometimes makes sense to create an object from other objects. For example, suppose you need an object to represent a course that you are taking in college. You decide to create a Course class, which will hold the following information:

- The course name
- The instructor's last name, first name, and office number
- The textbook's title, author, and publisher

In addition to the course name, the class will hold items related to the instructor and the textbook. You could put attributes for each of these items in the Course class. However, a good design principle is to separate related items into their own classes. In this example, an Instructor class could be created to hold the instructor-related data, and a TextBook class could be created to hold the textbook-related data. Instances of these classes could then be used as attributes in the Course class.

Let's take a closer look at how this might be done. To keep things simple, the Instructor class will have only the following functions:

- A default constructor that assigns empty strings to the instructor's last name, first name, and office number.
- A constructor that accepts arguments for the instructor's last name, first name, and office number
- set-a function that can be used to set all of the class's attributes
- print-a function that displays the object's attribute values

The code for the Instructor class is shown here:

## Contents of Instructor.h

```
#ifndef INSTRUCTOR
#define INSTRUCTOR
#include <iostream>
#include <string>
using namespace std;
// Instructor class
class Instructor
{
private:
    string lastName; // Last name
    string firstName; // First name
    string officeNumber; // Office number
public:
    // The default constructor stores empty strings
    // in the string objects.
    Instructor()
            { set("", "", ""); }
    // Constructor
    Instructor(string lname, string fname, string office)
            { set(lname, fname, office); }
    // set function
    void set(string lname, string fname, string office)
        { lastName = 1name;
                firstName = fname;
                officeNumber = office; }
        // print function
        void print() const
        { cout << "Last name: " << lastName << endl;
            cout << "First name: " << firstName << endl;
            cout << "Office number: " << officeNumber << endl; }
};
#endif
```

The code for the TextBook class is shown next. As before, we want to keep the class simple. The only functions it has are a default constructor, a constructor that accepts arguments, a set function, and a print function.

## Contents of TextBook.h

```
#ifndef TEXTBOOK
#define TEXTBOOK
#include <iostream>
#include <string>
using namespace std;
// TextBook class
class TextBook
```

```
{
private:
    string title; // Book title
    string author; // Author name
    string publisher; // Publisher name
public:
    // The default constructor stores empty strings
    // in the string objects.
    TextBook()
            { set("", "", ""); }
    // Constructor
    TextBook(string textTitle, string auth, string pub)
            { set(textTitle, auth, pub); }
    // set function
    void set(string textTitle, string auth, string pub)
            { title = textTitle;
                author = auth;
                pub1isher = pub; }
    // print function
    void print() const
        { cout << "Title: " << title << endl;
        cout << "Author: " << author << endl;
        cout << "Publisher: " << publisher << endl; }
};
#endif
```

The Course class is shown next. Notice the Course class has an Instructor object and a TextBook object as member variables. Those objects are used as attributes of the Course object. Making an instance of one class an attribute of another class is called object aggregation. The word aggregate means "a whole that is made of constituent parts." In this example, the Course class is an aggregate class because an instance of it is made of constituent objects.

When an instance of one class is a member of another class, it is said that there is a "has a" relationship between the classes. For example, the relationships that exist among the Course, Instructor, and TextBook classes can be described as follows:

- The course has an instructor.
- The course has a textbook.

The "has a" relationship is sometimes called a whole-part relationship because one object is part of a greater whole.

## Contents of Course.h

```
#ifndef COURSE
#define COURSE
#include <iostream>
#include <string>
#include "Instructor.h"
#include "TextBook.h"
using namespace std;
```

```
class Course
{
private:
    string courseName; // Course name
    Instructor instructor; // Instructor
    TextBook textbook; // Textbook
public:
        // Constructor
        Course(string course, string instrLastName,
            string instrFirstName, string instrOffice,
            string textTitle, string author,
            string publisher)
        { // Assign the course name.
            courseName = course;
            // Assign the instructor.
            instructor.set(instrLastName, instrFirstName, instrOffice);
            // Assign the textbook.
            textbook.set(textTitle, author, publisher); }
    // print function
    void print() const
    { cout << "Course name: " << courseName << endl << end1;
            cout << "Instructor Information:\n";
            instructor.print();
            cout << "\nTextbook Information:\n";
            textbook.print();
            cout << endl;}
};
#endif
```

Program 14-15 demonstrates the Course class.

## Program 14-15

```
// This program demonstrates the Course class.
#include "Course.h"
int main()
{
    // Create a Course object.
    Course myCourse("Intro to Computer Science", // Course name
        "Kramer", "Shawn", "RH3010", // Instructor info
        "Starting Out with C++", "Gaddis", // Textbook title and author
        "Pearson"); // Textbook publisher
        // Display the course info.
        myCourse.print();
        return 0;
} (program output continues)
```

```
Program 14-15 (continued)
Program Output
Course name: Intro to Computer Science
Instructor Information:
Last name: Kramer
First name: Shawn
Office number: RH3010
Textbook Information:
Title: Starting Out with C++
Author: Gaddis
Publisher: Pearson
```

## Using Member Initialization Lists with Aggregate Classes

Recall from Chapter 13 that in a constructor, you can use a member initialization list as an alternative way to initialize the class's member variables. An aggregate class's constructor can also use a member initialization list to call the constructors for each of its member objects. The following shows how we could rewrite the constructor for the Course class, using a member initialization list:

```
Course(string course, string instrLastName, string instrFirstName,
        string instrOffice, string textTitle, string author,
        string publisher) :
instructor(instrLastName, instrFirstName, instrOffice),
textbook(textTit1e, author, publisher)
{
    // Assign the course name.
    courseName = course;
}
```

In this version of the constructor, a colon appears at the end of the function header (line 3), followed by the member initialization list (lines 4 and 5). Line 4 calls the instructor member's constructor, passing the necessary arguments, and line 5 calls the textbook member's constructor, passing the necessary arguments. Notice in the initialization list we are using the names of the member objects, rather than their classes. This allows constructors of different objects of the same class to be invoked in the same initialization list.

## Aggregation in UML Diagrams

In Chapter 13, you were introduced to the Unified Modeling Language (UML) as a tool for designing classes. You show aggregation in a UML diagram by connecting two classes with a line that has an open diamond at one end. The diamond is closest to the class that is the aggregate. Figure 14-7 shows a UML diagram depicting the relationship between the Course, Instructor, and TextBook classes. The open diamond is closest to the Course class because it is the aggregate (the whole).

Figure 14-7 UML diagram showing aggregation

### 14.8 Focus on Object-Oriented Design: Class Collaborations

CONCEPT: It is common for classes to interact, or collaborate, with one another to perform their operations. Part of the object-oriented design process is identifying the collaborations between classes.

In an object-oriented application, it is common for objects of different classes to collaborate. This simply means objects interact with each other. Sometimes one object will need the services of another object in order to fulfill its responsibilities. For example, let's say an object needs to read a number from the keyboard then format the number to appear as a dollar amount. The object might use the services of the cin object to read the number from the keyboard then use the services of another object that is designed to format the number.

If one object is to collaborate with another object, then it must know something about the other object's member functions and how to call them. Let's look at an example.

The following code shows a class named Stock. An object of this class holds data about a company's stock. This class has two attributes: symbol and sharePrice. The symbol attribute holds the trading symbol for the company's stock. This is a short series of characters that are used to identify the stock on the stock exchange. For example, the XYZ Company's stock might have the trading symbol XYZ. The sharePrice attribute holds the current price per share of the stock. The class also has the following member functions:

- A default constructor that initializes symbol to an empty string and sharePrice to 0.0 .
- A constructor that accepts arguments for the symbol and share price.
- A copy constructor.
- set-a function that accepts arguments for the symbol and share price
- getSymbol-a function that returns the stock's trading symbol
- getSharePrice-a function that returns the current price of the stock

## Contents of Stock.h

```
#ifndef STOCK
#define STOCK
#include <string>
using namespace std;
class Stock
{
private:
    string symbol; // Trading symbol of the stock
    double sharePrice; // Current price per share
public:
    // Default constructor
    Stock()
                { set("", 0.0);}
    // Constructor
    Stock(const string sym, double price)
            { set(sym, price); }
        // Copy constructor
        Stock(const Stock &obj)
            { set(obj.symbol, obj.sharePrice); }
        // Mutator function
        void set(string sym, double price)
            { symbol = sym;
                sharePrice = price; }
    // Accessor functions
    string getSymbol() const
        { return symbol; }
```

```
    double getSharePrice() const
    { return sharePrice; }
};
#endif
```

The following code shows another class named StockPurchase that uses an object of the Stock class to simulate the purchase of a stock. The StockPurchase class is responsible for calculating the cost of the stock purchase. To do that, the StockPurchase class must know how to call the Stock class's getSharePrice function to get the price per share of the stock.

## Contents of StockPurchase.h

```
#ifndef STOCK_PURCHASE
#define STOCK_PURCHASE
#include "Stock.h"
class StockPurchase
{
private:
    Stock stock; // The stock that was purchased
    int shares; // The number of shares
public:
    // The default constructor sets shares to 0. The stock
    // object is initialized by its default constructor.
    StockPurchase()
                { shares = 0;}
    // Constructor
    StockPurchase(const Stock &stockObject, int numShares)
            { stock = stockObject;
                shares = numShares; }
    // Accessor function
    double getCost() const
        { return shares * stock.getSharePrice(); }
};
#endif
```

The second constructor for the StockPurchase class accepts a Stock object representing the stock that is being purchased, and an int representing the number of shares to purchase. In line 18, we see the first collaboration: the StockPurchase constructor makes a copy of the Stock object by using the Stock class's copy constructor. The next collaboration takes place in the getCost function. This function calculates and returns the cost of the stock purchase. In line 23, it calls the Stock class's getSharePrice function to determine the stock's price per share. Program 14-16 demonstrates this class.

## Program 14-16

```
// Stock trader program
#include <iostream>
#include <iomanip>
#include "Stock.h"
#include "StockPurchase.h"
using namespace std;
int main()
{
    int sharesToBuy; // Number of shares to buy
    // Create a Stock object for the company stock. The
    // trading symbol is XYZ and the stock is currently
    // priced at $9.62 per share.
    Stock xyzCompany("XYZ", 9.62);
    // Display the symbol and current share price.
    cout << setprecision(2) << fixed << showpoint;
    cout << "XYZ Company's trading symbol is "
            << xyzCompany.getSymbol() << endl;
    cout << "The stock is currently $"
        << xyzCompany.getSharePrice()
            << " per share.\n";
        // Get the number of shares to purchase.
        cout << "How many shares do you want to buy? ";
        cin >> sharesToBuy;
        // Create a StockPurchase object for the transaction.
        StockPurchase buy(xyzCompany, sharesToBuy);
    // Display the cost of the transaction.
    cout << "The cost of the transaction is $"
        << buy.getCost() << endl;
    return 0;
}
```

Program Output with Example Input Shown in Bold
XYZ Company's trading symbol is XYZ
The stock is currently $\$ 9.62$ per share.
How many shares do you want to buy? 100 Enter
The cost of the transaction is $\$ 962.00$

## Determining Class Collaborations with CRC Cards

During the object-oriented design process, you can determine many of the collaborations that will be necessary between classes by examining the responsibilities of the classes. In Chapter 13, we discussed the process of finding the classes and their responsibilities. Recall from that section that a class's responsibilities are:

- the things that the class is responsible for knowing.
- the actions that the class is responsible for doing.

Often you will determine that the class must collaborate with another class in order to fulfill one or more of its responsibilities. One popular method of discovering a class's responsibilities and collaborations is by creating CRC cards. CRC stands for class, responsibilities, and collaborations.

You can use simple index cards for this procedure. Once you have gone through the process of finding the classes (which was discussed in Chapter 13), set aside one index card for each class. At the top of the index card, write the name of the class. Divide the rest of the card into two columns. In the left column, write each of the class's responsibilities. As you write each responsibility, think about whether the class needs to collaborate with another class to fulfill that responsibility. Ask yourself questions such as:

- Will an object of this class need to get data from another object in order to fulfill this responsibility?
- Will an object of this class need to request another object to perform an operation in order to fulfill this responsibility?

If collaboration is required, write the name of the collaborating class in the right column, next to the responsibility that requires it. If no collaboration is required for a responsibility, simply write "None" in the right column, or leave it blank. Figure $14-8$ shows an example CRC card for the StockPurchase class.

Figure 14-8 CRC card

From the CRC card shown in the figure, we can see that the StockPurchase class has the following responsibilities and collaborations:

- Responsibility: To know the stock to purchase Collaboration: The Stock class
- Responsibility: To know the number of shares to purchase Collaboration: None
- Responsibility: To calculate the cost of the purchase Collaboration: The Stock class

When you have completed a CRC card for each class in the application, you will have a good idea of each class's responsibilities and how the classes must interact.

## Checkpoint

14.31 What are the benefits of having operator functions that perform object conversion?
14.32 Why are no return types listed in the prototypes or headers of operator functions that perform data type conversion?
14.33 Assume there is a class named BlackBox. Write the header for a member function that converts a BlackBox object to an int.
14.34 Assume there are two classes, Big and Sma11. The Big class has, as a member, an instance of the Small class. Write a sentence that describes the relationship between the two classes.

### 14.9 Focus on Object-Oriented Programming: Simulating the Game of Cho-Han

Cho-Han is a traditional Japanese gambling game in which a dealer uses a cup to roll two six-sided dice. The cup is placed upside down on a table so the value of the dice is concealed. Players then wager on whether the sum of the dice values is even (Cho) or odd (Han). The winner, or winners, take all of the wagers, or the house takes them if there are no winners.
We will develop a program that simulates a simplified variation of the game. The simulated game will have a dealer and two players. The players will not wager money, but will simply guess whether the sum of the dice values is even (Cho) or odd (Han). One point will be awarded to the player, or players, for correctly guessing the outcome. The game is played for five rounds, and the player with the most points is the grand winner.
In the program, we will use the Die class introduced in Chapter 13 to simulate the dice. We will create two instances of the Die class to represent two six-sided dice. In addition to the Die class, we will write the following classes:

- Dealer class: We will create an instance of this class to represent the dealer. It will have the ability to roll the dice, report the value of the dice, and report whether the total dice value is Cho or Han.
- Player class: We will create two instances of this class to represent the players. Instances of the Player class can store the player's name, make a guess between Cho or Han, and be awarded points.

First, let's look at the Dealer class.

## Contents of Dealer.h

```
// Specification file for the Dealer class
#ifndef DEALER_H
#define DEALER_H
#include <string>
#include "Die.h"
using namespace std;
```

7

```
class Dealer
{
private:
    Die die1; // Object for die #1
    Die die2; // Object for die #2
    int die1Value; // Value of die #1
    int die2Value; // Value of die #2
pub1ic:
    Dealer(); // Constructor
    void rollDice(); // To roll the dice
    string getChoOrHan(); // To get the result (Cho or Han)
    int getDie1Value(); /l To get the value of die #1
    int getDie2Value(); // To get the value of die #2
};
#endif
```

## Contents of Dealer.cpp

```
// Implementation file for the Dealer class
#include "Dealer.h"
#include "Die.h"
#include <string>
using namespace std;
//*************
|/**********************************************
Dea1er::Dea1er()
{
    // Set the intial dice values to 0.
    // (We will not use these values.)
    die1Value = 0;
    die2Value = 0;
}
//*********************************************
// The rollDice member function rolls the
// dice and saves their values.
//********************************************
void Dealer::rol1Dice()
{
    // Roll the dice.
    die1.rol1();
    die2.rol1();
    // Save the dice values.
    die1Value = die1.getValue();
    die2Va1ue = die2.getVa1ue();
}
```

```
//*********************************************
// The getChoOrHan member function returns *
// the result of the dice roll, Cho (even)
// or Han (odd).
//*********************************************
string Dealer::getChoOrHan()
{
    string result; // To hold the result
        // Get the sum of the dice.
        int sum = die1Value + die2Value;
        // Determine even or odd.
        if (sum % 2 == 0)
            result = "Cho (even)";
        else
            result = "Han (odd)";
        // Return the result.
        return result;
}
//********************************************

{
    return die1Value;
}
//********************************************
// The getDie2Value member function returns
// the value of die #2.
//********************************************
int Dealer::getDie2Value()
{
    return die2Value;
}
```

Here is a synopsis of the class members:
die1 Declared in line 11 of Dealer.h. This is an instance of the Die class, to represent die \#1.
die2 Declared in line 12 of Dealer.h. This is an instance of the Die class, to represent die \#2.
die1Value Declared in line 13 of Dealer.h. This member variable will hold the value of die \#1 after it has been rolled.
die2Value Declared in line 14 of Dealer.h. This member variable will hold the value of die \#1 after it has been rolled.
Constructor Lines 10 through 16 of Dealer.cpp initializes the die1Value and die2Value fields to 0 .
rollDice Lines 22 through 31 of Dealer.cpp. This member function simulates the rolling of the dice. Lines 25 and 26 call the Die objects' ro 11 method. Lines 29 and 30 save the value of the dice in the die1Value and die2Value member variables.
getChoOrHan Lines 38 through 53 of Dealer.cpp. This member function returns a string indicating whether the sum of the dice is Cho (even) or Han (odd).
getDie1Value Lines 59 through 62 of Dealer.cpp. This member function returns the value of first die (stored in the die1Value member variable).
getDie2Value Lines 68 through 71 of Dealer.cpp. This member function returns the value of first die (stored in the die2Value member variable).

Now, let's look at the Player class.

## Contents of Player.h

```
// Specification file for the Player class
#ifndef PLAYER_H
#define PLAYER_H
#include <string>
using namespace std;
class Player
{
private:
    string name; // The player's name
    string guess; // The player's guess
    int points; // The player's points
pub1ic:
        Player(string); // Constructor
    void makeGuess(); // Causes player to make a guess
    void addPoints(int); // Adds points to the player
    string getName(); // Returns the player's name
    string getGuess(); // Returns the player's guess
    int getPoints(); // Returns the player's points
};
#endif
```

## Contents of Player. cpp

```
// Implementation file for the Player class
#include "Player.h"
#include <cstdlib>
#include <ctime>
#include <string>
using namespace std;
//***********************************************

11 Player::Player(string playerName)
```

```
{
        // Seed the random number generator.
        srand(time(0));
        name = playerName;
        guess = "";
        points = 0;
    }
//************************************************
// The makeGuess member function causes the
// player to make a guess, either "Cho (even)" *
// or "Han (odd)".
//************************************************
void Player::makeGuess()
{
    const int MIN_VALUE = 0;
    const int MAX_VALUE = 1;
    int guessNumber; // For the user's guess
    // Get a random number, either 0 or 1.
    guessNumber = (rand() % (MAX_VALUE - MIN_VALUE + 1)) + MIN_VALUE;
    // Convert the random number to Cho or Han.
    if (guessNumber == 0)
        guess = "Cho (even)";
    else
        guess = "Han (odd)";
}
//***********************************************
// The addPoints member function adds a
// specified number of points to the player's
// current balance.
//************************************************
void Player::addPoints(int newPoints)
{
    points += newPoints;
}
/l***************************************************
// The getName member function returns a *
// player's name.
/|**************************************************
string Player::getName()
{
    return name;
}
//************************************************
// The getGuess member function returns a
// player's guess.
//************************************************
```

```
string Player::getGuess()
{
    return guess;
}
//***********************************************
// The getPoints member function returns a *
// player's points.
//***********************************************
int Player::getPoints()
{
        return points;
}
```

Here is a synopsis of the class members:
name Declared in line 10 of Player.h. This member variable will hold the player's name.
guess Declared in line 11 of Player.h. This member variable will hold the player's guess.
points Declared in line 12 of Player.h. This member variable will hold the player's points.
Constructor Lines 11 through 19 of Player.cpp, accepts an argument for the player's name, which is assigned to the name field. The guess field is assigned an empty string, and the points field is set to 0 .
makeGuess Lines 26 through 41 of Player.cpp. This member function causes the player to make a guess. The function generates a random number that is either a 0 or a 1. The if statement that begins at line 37 assigns the string "Cho (even)" to the guess member variable if the random number is 0 , or it assigns the string "Han (odd)" to the guess member variable if the random number is 1.
addPoints Lines 48 through 51 of Player.cpp. This member function adds the number of points specified by the argument to the player's point member variable.
getName Lines 57 through 60 of Player.cpp. This member function returns the player's name.
getGuess Lines 66 through 69 of Player.cpp. This member function returns the player's guess.
getPoints Lines 75 through 78 of Player.cpp. This member function returns the player's points.

Program 14-17 uses these classes to simulate the game. The main function simulates five rounds of the game, displaying the results of each round, then displays the overall game results.

## Program 14-17

```
// This program simulates the game of Cho-Han.
#include <iostream>
#include <string>
#include "Dealer.h"
#include "Player.h"
using namespace std;
```

## Program 14-17 (continued)

```
// Function prototypes
void roundResults(Dealer &, Player &, Player &);
void checkGuess(Player &, Dealer &);
void displayGrandWinner(Player, Player);
int main()
{
    const int MAX_ROUNDS = 5; // Number of rounds
    string player1Name; // First player's name
    string player2Name; // Second player's name
    // Get the player's names.
    cout << "Enter the first player's name: ";
    cin >> player1Name;
    cout << "Enter the second player's name: ";
    cin >> player2Name;
    // Create the dealer.
    Dealer dealer;
    // Create the two players.
    Player player1(player1Name);
    Player player2(player2Name);
    // Play the rounds.
    for (int round = 0; round < MAX_ROUNDS; round++)
    {
        cout << "----------------------------\n";
        cout << "Now playing round " << (round + 1)
                << endl;
        // Roll the dice.
        dealer.rollDice();
        // The players make their guesses.
        player1.makeGuess();
        player2.makeGuess();
        // Determine the winner of this round.
        roundResults(dealer, player1, player2);
    }
    // Display the grand winner.
    displayGrandWinner(player1, player2);
    return 0;
}
/|*****************************************************
// The roundResults function determines the results *
// of the current round.
/|*********************************************************
void roundResults(Dealer &dealer, Player &player1, Player &player2)
```

## Program Output with Example Input Shown in Bold

```
Enter the first player's name: Bill Enter
Enter the second player's name: Jill Enter
```

Now playing round 1
The dealer rolled 4 and 6
Result: Cho (even)
The player Bill guessed Cho (even)
Awarding 1 point(s) to Bill
The player Jill guessed Cho (even)
Awarding 1 point(s) to Jill
Now playing round 2
The dealer rolled 5 and 2
Result: Han (odd)
The player Bill guessed Han (odd)
Awarding 1 point(s) to Bill
The player Jill guessed Han (odd)
Awarding 1 point(s) to Jill
Now playing round 3
The dealer rolled 4 and 2
Result: Cho (even)
The player Bill guessed Cho (even)
Awarding 1 point(s) to Bill

```
The player Jill guessed Cho (even)
Awarding }1\mathrm{ point(s) to Jill
Now playing round 4
The dealer rolled 3 and 2
Result: Han (odd)
The player Bill guessed Han (odd)
Awarding }1\mathrm{ point(s) to Bil1
The player Jill guessed Cho (even)
Now playing round 5
The dealer rolled 4 and 6
Result: Cho (even)
The player Bill guessed Han (odd)
The player Jill guessed Han (odd)
--------------------------
Game over. Here are the results:
Bil1: 4 points
Jil1: 3 points
Bill is the grand winner!
```

Let's look at the code. Here is a summary of the main function:

- Lines 15 through 17 make the following declarations: MAX_ROUNDS-the number of rounds to play, player1Name-to hold the name of player \#1, and player2Name-to hold the name of player \#2.
- Lines 20 through 23 prompt the user to enter the player's names.
- Line 26 creates an instance of the Dealer class to represent the dealer.
- Line 29 creates an instance of the Player class to represent player \#1. Notice player 1 Name is passed as an argument to the constructor.
- Line 30 creates another instance of the Player class to represent player \#2. Notice player2Name is passed as an argument to the constructor.
- The for loop that begins in line 33 iterates five times, causing the simulation of five rounds of the game. The loop performs the following actions:
- Line 40 causes the dealer to roll the dice.
- Line 43 causes player \#1 to make a guess (Cho or Han).
- Line 44 causes player \#2 to make a guess (Cho or Han).
- Line 47 passes the dealer, player1, and player 2 objects to the roundResults function. The function displays the results of this round.
- Line 51 passes the player1 and player2 objects to the displayGrandWinner function, which displays the grand winner of the game.

The roundResults function, which displays the results of a round, appears in lines 59 through 71 . Here is a summary of the function:

- The function accepts references to the dealer, player1, and player2 objects as arguments.
- The statement in lines 62 and 63 displays the value of the two dice.
- Line 66 calls the dealer object's getChoOrHan function to display the results, Cho or Han.
- Line 69 calls the checkGuess function, passing the player1 and dealer objects as arguments. The checkGuess function compares a player's guess to the dealer's result (Cho or Han), and awards points to the player if the guess is correct.
- Line 70 calls the checkGuess function, passing the player 2 and dealer objects as arguments.

The checkGuess function, which compares a player's guess to the dealer's result, awarding points to the player for a correct guess, appears in lines 77 through 99 . Here is a summary of the function:

- The function accepts references to a Player object and the Dealer object as arguments.
- Line 79 declares the constant POINTS_TO_ADD, set to the value 1 , which is the number of points to add to the player's balance if the player's guess is correct.
- Line 82 assigns the player's guess to the string object guess.
- Line 85 assigns the dealer's results (Cho or Han) to the string object choHanResult.
- The statement in lines 88 and 89 displays the player's name and guess.
- The if statement in line 92 compares the player's guess to the dealer's result. If they match, then the player guessed correctly, and line 94 awards points to the player.

The displayGrandWinner function, which displays the grand winner of the game, appears in lines 105 through 133 . Here is a summary of the function:

- The function accepts the player1 and player2 objects as arguments.
- The statements in lines 111 through 116 display both players' names and points.
- The if-else-if statement that begins in line 119 determines which of the two players has the highest score and displays that player's name as the grand winner. If both players have the same score, a tie is declared.

### 14.10 Rvalue References and Move Semantics

CONCEPT: A move operation transfers resources from a source object to a target object. A move operation is appropriate when the source object is temporary and is about to be destroyed.
$\mathrm{C}++$ has always been regarded as a high-performance language. Typically, it is the language of choice for developers who need to write fast, efficient code. The C++ 11 standard introduced new features that make C++ even faster and more efficient. One of these new features is the ability to use move semantics in your classes. In certain situations, you can use move semantics to greatly improve the performance of assignment operations. You can also use move semantics to write a new type of constructor known as a move constructor. Before we can discuss move semantics, however, we must introduce another new topic: rvalue references.

## Lvalues and Rvalues

During the execution of a program, numerous entities, such as variables, class objects, and so on, are created in memory. For example, look at the following main function:

```
int main()
{
    int x = 0;
    x = 12;
    cout << x << endl;
    return 0;
}
```

In this code, an int variable named x is created in line 3. Although the variable is created by the statement in line 3, it is meant to be accessible to other statements. In fact, any statement in the variable's scope can use the name x to access the variable. For example, line 5 assigns the value 12 to the x variable, and line 6 displays the contents of the x variable.

Some entities, such as the variable x in the previous example, are created by definition statements and meant to exist in memory long enough for other statements to access them. Other entities, however, are meant to exist only temporarily. For example, look at the following code fragment:

```
int x;
x = 2 * 6;
```

When the second statement executes, the system evaluates the expression on the right side of the $=$ operator. In this case, it gets the value of 2 * 6 and stores the result, 12, as a temporary value. Then, it copies the temporary value to the x variable. After the statement executes, the temporary value is no longer needed, so the system discards it.

Values that are returned from functions are also stored as temporary values. When a function returns a value, you have to immediately do something with the value, or you will lose it. For example, look at the following code fragment:

```
int square(int a)
{
    return a * a;
}
int main()
{
    int x = 0;
    x = square(5);
    cout << x << endl;
    return 0;
}
```

Consider the statement in line 10 . We can summarize the statement by saying it calls the square function, and assigns the value that is returned from the square function to the variable x . But more specifically, all of the following things happen when this statement executes:

- The square function is called, and the value 5 is passed as an argument.
- The square function calculates 5 * 5 and stores the result, 25 , as a temporary value.
- The temporary value is copied (assigned) to the variable $x$.
- The temporary value is no longer needed, so the system discards it.

To further illustrate this, look at the following code fragment:

```
int square(int a)
{
    return a * a;
}
int main()
```

```
{
        int x = 0;
        square(5);
        cout << x << endl;
        return 0;
    }
```

In this code, the statement in line 10 calls the square function, but it doesn't do anything with the value that is returned. As in the previous example, the value 25 is stored as a temporary value. But, in this example, the value is lost forever after the statement has finished executing.

So, we have two types of values stored in memory during the execution of a program:

- Values that persist beyond the statement that created them, and have names that make them accessible to other statements in the program. In C++, these values are called lvalues.
- Values that are temporary, and cannot be accessed beyond the statement that created them. In C++, these values are called rvalues.

TIP: Perhaps the simplest way to think of an lvalue is this: it is an expression that can be written on the left side of an assignment operator.

## Rvalue References

In Chapter 6, you learned that a reference variable is a variable that refers to the memory location of another variable. For example, look at the following code fragment:

```
int x = 34;
int &ref = x;
```

In this code, the variable ref is a reference variable. In a declaration, a reference is indicated by the presence of an ampersand (\&) between the type and the variable's identifier. In C++ 11 and later, this type of reference is called an lvalue reference because it can refer only to lvalues.
$\mathrm{C}++11$ also introduces the concept of an rvalue reference, which is a reference variable that can refer only to temporary objects that would otherwise have no name. An rvalue reference is declared similarly to an lvalue reference, except with a double ampersand (\&\&). The code below uses an rvalue reference to print the square of 5:

```
int &&rvalRef = square(5);
cout << rvalRef << endl;
```

The first statement calls the square function, passing 5 as an argument. The function returns the value 25 , which is stored as a temporary value. The address of the temporary value is then assigned to rvalRef. So, now we have given a name to the temporary value, so it can be accessed by other statements.

When you assign an rvalue reference to a temporary value, you are giving a name to the temporary value and making it possible to access the value from other parts of the program. Therefore, you are transforming a temporary value into an lvalue. Because an rvalue reference cannot refer to an lvalue, the following code will not compile:

```
int x = 0;
int &&rvalRef = x; // Error!
```

Look at the following initialization statement:

```
int &&rvalRef1 = square(5);
```

After this statement executes, the memory location containing the value returned by square(5) has a name, rvalRef1, so rvalRef1 itself becomes an lvalue. This means that a subsequent initialization statement such as:

```
int &&rvalRef2 = rvalRef1; // Error!
```

will not compile, because rvalRef1 is no longer an rvalue. Fortunately, there is a positive consequence of all this: a temporary object can have at most one lvalue reference pointing to it. If a function has an lvalue reference to a temporary object, you can be sure no other part of the program has access to the same object. This fact is important in understanding how move operations, to be discussed next, work.

## Move Semantics

When objects are passed as arguments into functions, and returned from functions, the program does a lot of work behind the scenes, allocating memory and copying values. To illustrate, let's look at the Person class.

```
#ifndef PERSON_H
#define PERSON_H
#include <cstring>
using namespace std;
class Person
{
private:
    char *name = nullptr;
public:
    // Default constructor
    Person()
    { name = new char[1];
        *name = 0; }
    // Constructor with a parameter
    Person(char *n)
    { name = new char[strlen(n) + 1];
        strcpy(name, n); }
    // Copy constructor
    Person(const Person &obj)
    { name = new char[strlen(obj.name) + 1];
        strcpy(name, obj.name); }
    // Destructor
    ~Person()
    { delete name; }
```

```
    // Copy assignment operator
    Person & operator=(const Person &right)
    { if (this != &right)
    {
            name = new char[strlen(right.name) + 1];
            strcpy(name, right.name);
        }
        return *this; }
    // getName member function
    char *getName() const
    { return name; }
};
#endif
```

The Person class has three constructors: a default constructor, a parameterized constructor, and a copy constructor. It also has an overloaded = operator, and a member function to get the name member variable. We are going to use this class to demonstrate some of the work that happens when an object is passed around in a program. But first, we are going to insert some cout statements so we can see when the constructors and the destructor are called, as well as the overloaded = operator. The modified class is shown here, followed by Program 14-18 which demonstrates the class.

## Contents of Person.h

```
#ifndef PERSON_H
#define PERSON_H
#include <iostream>
#include <cstring>
using namespace std;
class Person
{
private:
    char *name;
public:
    // Default constructor
    Person()
    { cout << "*** default constructor ***\n";
        name = nullptr; }
    // Constructor with a parameter
    Person(char *n)
    { cout << "*** parameterized constructor ***\n";
            name = new char[strlen(n) + 1];
            strcpy(name, n); }
    // Copy constructor
    Person(const Person &obj)
    { cout << "*** copy constructor ***\n";
            name = new char[strlen(obj.name) + 1];
            strcpy(name, obj.name); }
```

```
    // Destructor
    ~Person()
    { cout << "*** destructor ***\n";
        delete [] name; }
    // Overloaded = operator
    Person & operator=(const Person &right)
    { cout << "*** assignment operator ***\n";
        if (this != &right)
        {
                if (name != nullptr)
                    delete[] name;
                name = new char[strlen(right.name) + 1];
                strcpy(name, right.name);
        }
        return *this; }
    // getName member function
    char *getName() const
        { return name; }
};
#endif
```

## Program 14-18

```
#include <iostream>
#include <string>
#include "Person.h"
using namespace std;
// Function prototype
Person makePerson();
void displayPerson(Person);
int main()
{
    Person person;
    person = makePerson();
    displayPerson(person);
    return 0;
}
Person makePerson()
{
    Person p("Wil1 MacKenzie");
    return p;
}
void displayPerson(Person p2)
{
    cout << p2.getName() << end1;
}
```

```
Program 14-18
(continued)
Program Output

*** destructor ***
(9) p2 parameter object destroyed
*** destructor ***
(10) person object in main destroyed
```

In the program's output, the comments that are shown to the right, in a different color, are not part of the output. We have added those so we can refer to specific lines in our discussion.

Let's step through the execution of the program, and take a closer look at its output:

- In the main function, the statement in line 12 creates a local Person object named person. This statement causes the Person class's default constructor to execute, displaying the output in line (1).
- Line 13 calls the makePerson function. Inside the makePerson function, the statement in line 20 creates a Person object named p , passing "Will MacKenzie" to the constructor. This causes the output in line (2) to be displayed.
- In line 21, the makePerson function returns the Person object named p. Before the function terminates, however, a temporary object is created, as a copy of the p object. This causes the temporary object's copy constructor to be called, displaying the output in line (3).
- As the makePerson function terminates, the p object is destroyed, causing the output in line (4) to be displayed.
- In line 13, the temporary object is assigned to the person object. This causes the Person class's overloaded = operator to be called, displaying the output in line (5).
- The temporary object is destroyed, causing the Person class's destructor to be called. This displays the output in line (6).
- Line 14 calls the displayPerson function, passing the person object as an argument.
- In line 24 , the p2 parameter object is created as a copy of the person object. This calls the copy constructor, and displays the output in line (7).
- Line 26 displays the output shown in line (8).
- The displayPerson function terminates, causing the p2 parameter to be destroyed. This calls the Person class's destructor, displaying the output in line (9).
- In main, line 15 ends the program, causing the person object to be destroyed. The output in line (10) is displayed by the Person class's destructor.

We are especially interested in line 13:

```
person = makePerson();
```

that calls the makePerson() function:

```
Person makePerson()
{
    Person p("Wi11 MacKenzie");
    return p;
}
```

The makePerson() function creates a local Person object named $p$. When the function returns $p$, a temporary object is created as a copy of $p$. This causes the Person class's copy constructor to execute. The copy constructor allocates a block of memory to hold the name array, then copies the name array from $p$ to the temporary object.

Then in line 13 , the overloaded assignment operator executes to copy the temporary object to the person object. The overloaded assignment operator also allocates a block of memory, and copies the name array from the temporary object to the person object. As you can see, the copy assignment goes to great lengths to avoid pointer sharing between the temporary object and the person object, but then right after that, the temporary object is destroyed and its name array is deleted.

With C++ 11, we can add another assignment operator function, known as a move assignment operator, to the Person class. The idea behind the move assignment operator is to avoid all this work by simply swapping the members of the object being assigned with the temporary object. That way, when the temporary object is destroyed, its destructor deletes the memory that was previously owned by person, and person avoids having to copy the elements that were in the temporary object's name array.

The move assignment operator function for the Person class follows. To simplify the code, we have used the STL library function swap to swap the contents of two memory locations. The swap function is declared in the <algorithm> header file (you will learn more about the functions in the <algorithm> header file in Chapter 17).

```
// Move assignment operator
Person& operator=(Person&& right)
{ if (this != &right)
    {
        swap(name, right.name);
    }
    return *this;
}
```

Compare the class's move assignment operator to the class's copy assignment operator:

```
// Copy assignment operator
Person & operator=(const Person &right)
{ if (this != &right)
    {
        name = new char[strlen(right.name) + 1];
        strcpy(name, right.name);
    }
    return *this;
}
```

Notice the function header for the move assignment operator is different from the function header for the copy assignment operator in two ways:

- The move assignment operator takes an rvalue reference as parameter. This is because a move assignment should only be performed when the source of the assignment is a temporary object.
- The parameter in the move assignment operator is not const. This is because "moving" a resource from an object modifies it.

The move assignment, introduced in C++ 11, is much more efficient than copy assignment, and it should be used whenever the object being assigned from is temporary. There is also a move constructor, which should be used when creating a new object by initialization from a temporary object.

If you add a move assignment operator to a class, you should also add a move constructor to the class. A move constructor avoids unnecessary copying of data by "stealing" it from the temporary object. Here is the move constructor for the Person class. Again, note the parameter to the constructor is an rvalue reference, denoting that the parameter is a temporary object.

```
// Move constructor
Person(Person&& temp)
{ // Steal the name pointer from temp.
    name = temp.name;
    // Nullify the temp object's name pointer.
    temp.name = nullptr;
}
```

Note the parameter in the move constructor cannot be const. In addition, the temporary object that is the source for the move constructor must be left in a state that will allow its destructor to run without causing errors. That is why, in the Person class's move constructor, we set the temporary object's name pointer to nullptr before the function ends.

## When to Implement Move Semantics in a Class

Anytime you write a class that contains a pointer or a reference to an outside piece of data, you should include a copy constructor, a move constructor, a copy assignment operator, and a move assignment operator. By adding move operations to such a class, you will ensure the best performance for your code.

At runtime, the move constructor and move assignment operator are automatically called when appropriate. Specifically, the compiler uses a move operation whenever an object is being assigned the value of a temporary object, or initialized with a copy of a temporary object.

## Default Operations Provided by the Compiler

The motivation for writing copy constructors, move constructors, copy assignment operators, move assignment operators, and destructors is to make sure a class properly manages and disposes of resources, such as dynamically allocated memory. Writing all of these operations for each class can be tedious, so the compiler tries to help out
by generating default implementations for them. Let's assume we compile the following class:

```
class MyClass
{
private:
    int mydata = 0;
public:
    int getMyData()
    { return mydata; }
    void setMyData(int d)
    { mydata = d; }
};
```

The compiler will automatically generate the following:

- A default constructor MyCl ass ()
- A copy constructor MyCl ass (const MyCl ass \&)
- A copy assignment operator MyCl ass \& operator=(const Myclass \&)
- A move constructor MyCl ass ( MyCl ass $\& \&$ )
- A destructor $\sim \operatorname{MyClass}()$

Keep in mind if you write your own version of any of these member functions, the compiler will not provide any of the default versions. So, if you write one of these member functions, you should write all of the others as well. For example, if you write a copy constructor for a class, then you should also write a move constructor, a copy assignment operator, a move assignment operator, and a destructor.

## Review Questions and Exercises

## Short Answer

1. Describe the difference between an instance member variable and a static member variable.
2. Suppose that a class Myclass has a static member function declared as follows:
static void func_static();
Give two alternative ways to call this function.
3. A class CountUp has a static member variable count of data type integer. How can the value of the variable count be initialized to 0 ?
4. What is a friend function?
5. Why is it not always a good idea to make an entire class a friend of another class?
6. What is memberwise assignment?
7. When is a copy constructor called?
8. How can the compiler determine if a constructor is a copy constructor?
9. Describe a situation where memberwise assignment is not desirable.
10. Why must the parameter of a copy constructor be a reference?
11. What is a default copy constructor?
12. Why would a programmer want to overload operators rather than use regular member functions to perform similar operations?
13. What is passed to the parameter of a class's operator= function?
14. Why shouldn't a class's overloaded = operator be implemented with a void operator function?
15. How does the compiler know whether an overloaded ++ operator should be used in prefix or postfix mode?
16. What is the this pointer?
17. What type of value should be returned from an overloaded relational operator function?
18. The class Stuff has both a copy constructor and an overloaded = operator. Assume blob and clump are both instances of the Stuff class. For each statement below, indicate whether the copy constructor or the overloaded = operator will be called:
```
Stuff blob = clump;
clump = blob;
blob.operator=(clump);
showValues(blob); // blob is passed by value.
```

19. Explain the programming steps necessary to make a class's member variable static.
20. Explain the programming steps necessary to make a class's member function static.
21. Consider the following class declaration:
```
class Thing
{
private:
    int x;
    int y;
    static int z;
public:
    Thing()
        { x = y = z; }
    static void putThing(int a)
        { z = a; }
};
```

Assume a program containing the class declaration defines three Thing objects with the following statement:
Thing one, two, three;
How many separate instances of the x member exist?
How many separate instances of the $y$ member exist?
How many separate instances of the $z$ member exist?
What value will be stored in the $x$ and $y$ members of each object?
Write a statement that will call the PutThing member function before the objects above are defined.
22. Describe the difference between making a class a member of another class (object aggregation), and making a class a friend of another class.
23. What is the purpose of a forward declaration of a class?
24. Explain why memberwise assignment can cause problems with a class that contains a pointer member.
25. Why is a class's copy constructor called when an object of that class is passed by value into a function?

## Fill-in-the-Blank

26. If a member variable is declared $\qquad$ , all objects of that class have access to the same variable.
27. The lifetime of a static data member of a class is $\qquad$ , but its visibility is $\qquad$ .
28. A function can access the private data members of a number of classes provided that it is declared as $\qquad$ in the definition of all the classes it accesses.
29. A static member function may be called $\qquad$ any instances of its class are defined.
30. A(n) $\qquad$ function is not a member of a class, but has access to the private members of the class.
31. $\mathrm{A}(\mathrm{n})$ $\qquad$ tells the compiler that a specific class will be declared later in the program.
32. When the arithmetic assignment operator is overloaded, the object at the $\qquad$ side of the operator is passed as an argument.
33. A(n) $\qquad$ is a special constructor, called whenever a new object is initialized with another object's data.
34. Conversion of a class object to a basic data type or an object of another class is known as $\qquad$ .
35. $\qquad$ redefines existing $\mathrm{C}++$ operators.
36. Binary operators overloaded with friend functions take $\qquad$ explicit argument(s).
37. Making an instance of one class a member of another class is called $\qquad$ .
38. Object aggregation is useful for creating a(n) $\qquad$ relationship between two classes.

## Algorithm Workbench

39. Assume that a class Point2D exists. Write the header for a member function that overloads the + operator for that class.
40. Assume a class named Dollars exists. Write the headers for member functions that overload the prefix and postfix ++ operators for that class.
41. Assume a class named Complex exists. Write the header for a member function that overloads the >= operator for that class.
42. Assume a class named Length exists. Write the header for a member function that overloads cout's << operator for that class.
43. Assume a class named Collection exists. Write the header for a member function that overloads the [] operator for that class.

## True or False

44. T F Static member variables cannot be accessed by nonstatic member functions.
45. T F The lifetime of a static member variable is the lifetime of the program.
46. T F A static member function may refer to nonstatic member variables of the same class, but only after an instance of the class has been defined.
47. T F A friend function can be called by using an object of the class where it is declared as friend.
48. T F A friend function has access to the private members of the class declaring it a friend.
49. T F A class method may be a friend function of another class.
50. T F The compiler will report an error if the + operator is overloaded in a way so that it performs subtraction.
51. T F If a class has a pointer as a member, it's a good idea to also have a copy constructor.
52. T F When a unary operator is overloaded using a member function, it accepts one explicit argument and returns a class object.
53. T F If a class doesn't have a copy constructor, the compiler generates a default copy constructor for it.
54. T F If a class has a copy constructor, and an object of that class is passed by value into a function, the function's parameter will not call its copy constructor.
55. T F The size of an operator cannot be overloaded.
56. T F Operator overloading also allows creation of new operators.
57. T F To convert a class object to basic data type, a conversion operator needs to be included publicly within the class.
58. T F It is possible to have an instance of one class as a member of another class.

## Find the Errors

Each of the following class declarations has errors. Locate as many as you can.

```
59. class Box
    {
        private:
            double width;
            double length;
            double height;
        public:
            Box(double w, 1, h)
                { width = w; length = 1; height = h; }
            Box(Box b) // Copy constructor
                { width = b.width;
                length = b.length;
                height = b.height; }
    ... Other member functions follow...
    };
60. class Circle
    {
    private:
        double diameter;
        int centerX;
        int centerY;
    public:
        Circle(double d, int x, int y)
            { diameter = d; center X = x; centerY = y; }
            // Overloaded = operator
            void Circle=(Circle &right)
            { diameter = right.diameter;
                centerX = right.centerX;
                centerY = right.centerY; }
    ... Other member functions follow ...
    };
```

```
61. class Complex
    {
        private:
            int real;
            float imaginary;
        public:
            Complex (int r, float i)
                { real = r; imaginary = i; }
            // Overloaded * operator
            void operator *(const * Complex right)
            { real = real * right.real;
            imaginary = imaginary * right.imaginary;
            }
        ... Other member functions follow ...
    };
62. class Box
    {
        private:
            double width;
            double length;
            double height;
        public:
        Box(double w, 1, h)
            { width = w; length = 1; height = h; }
        // Overloaded prefix ++ operator
        void operator++()
            { ++width; ++length;}
        // Overloaded postfix ++ operator
        void operator++()
            { width++; length++;}
    ... Other member functions follow ...
};
63. class Yard
    {
        private:
            float length;
        public:
        yard(float 1)
            { length = 1; }
            // float conversion function
            void operator float()
                { return length; }
    ... Other member functions follow ...
};
```

## Programming Challenges

## 1. Participant Class

Design a Participant class used for listing candidates who have registered for a seminar. The class should record the following data about each participant:

- Name of the participant, including the first name and last name.
- The organisation with which the participant is associated.

The class should have two other member variables, total_candidates and serial_ number. The variable total_candidates should record the total number of candidates registered and the variable serial_number should record the serial number of the participants.
The class should include the following member functions:

- constructor-increments total_candidates and assigns serial_number as the current value of the total number of registered candidates to the last candidate.
- setRecord-inputs the other member variables.
- getRecord-displays the record of a participant.
- showTotal-displays the total number of participants.

Demonstrate the class in a full program.

## 2. Day of the Year

Assuming a year has 365 days, write a class named DayOfYear that takes an integer representing a day of the year and translates it to a string consisting of the month followed by day of the month. For example,

Day 2 would be January 2.
Day 32 would be February 1.
Day 365 would be December 31 .
The constructor for the class should take as parameter an integer representing the day of the year, and the class should have a member function print () that prints the day in the month-day format. The class should have an integer member variable to represent the day, and should have static member variables holding string objects that can be used to assist in the translation from the integer format to the month-day format.
Test your class by inputting various integers representing days and printing out their representation in the month-day format.

## 3. Day of the Year Modification

Modify the DayOfYear class, written in Programming Challenge 2, to add a constructor that takes two parameters: a string object representing a month and an integer in the range 0 through 31 representing the day of the month. The constructor should then initialize the integer member of the class to represent the day specified by the month and day of month parameters. The constructor should terminate the program with an appropriate error message if the number entered for a day is outside the range of days for the month given.

Add the following overloaded operators:
++ prefix and postfix increment operators. These operators should modify the DayOfYear object so it represents the next day. If the day is already the end of the year, the new value of the object will represent the first day of the year.
-- prefix and postfix decrement operators. These operators should modify the DayOfYear object so it represents the previous day. If the day is already the first day of the year, the new value of the object will represent the last day of the year.

## 4. NumDays Class

Design a class called NumDays. The class's purpose is to store a value that represents a number of work hours and convert it to a number of days. For example, 8 hours would be converted to 1 day, 12 hours would be converted to 1.5 days, and 18 hours would be converted to 2.25 days. The class should have a constructor that accepts a number of hours, as well as member functions for storing and retrieving the hours and days. The class should also have the following overloaded operators:

+ Addition operator. When two NumDays objects are added together, the overloaded + operator should return the sum of the two objects' hours members.
- Subtraction operator. When one NumDays object is subtracted from another, the overloaded - operator should return the difference of the two objects' hours members.
++ Prefix and postfix increment operators. These operators should increment the number of hours stored in the object. When incremented, the number of days should be automatically recalculated.
-- Prefix and postfix decrement operators. These operators should decrement the number of hours stored in the object. When decremented, the number of days should be automatically recalculated.

5. Time Off

NOTE: This assignment assumes you have already completed Programming Challenge 4.

Design a class named TimeOff. The purpose of the class is to track an employee's sick leave, vacation, and unpaid time off. It should have, as members, the following instances of the NumDays class described in Programming Challenge 4:

| maxSickDays | A NumDays object that records the maximum number of days of <br> sick leave the employee may take. |
| :--- | :--- |
| sickTaken | A NumDays object that records the number of days of sick leave the <br> employee has already taken. |
| maxVacation | A NumDays object that records the maximum number of days of <br> paid vacation the employee may take. |
| vacTaken | A NumDays object that records the number of days of paid vacation <br> the employee has already taken. |

maxUnpaid A NumDays object that records the maximum number of days of unpaid vacation the employee may take.
unpaidTaken A NumDays object that records the number of days of unpaid leave the employee has taken.
Additionally, the class should have members for holding the employee's name and identification number. It should have an appropriate constructor and member functions for storing and retrieving data in any of the member objects.
Input Validation: Company policy states that an employee may not accumulate more than 240 hours of paid vacation. The class should not allow the maxVacation object to store a value greater than this amount.

## 6. Personnel Report

NOTE: This assignment assumes you have already completed Programming Challenges 4 and 5.

Write a program that uses an instance of the TimeOff class you designed in Programming Challenge 5. The program should ask the user to enter the number of months an employee has worked for the company. It should then use the TimeOff object to calculate and display the employee's maximum number of sick leave and vacation days. Employees earn 12 hours of vacation leave and 8 hours of sick leave per month.

## 7. Angle Class

Design a class named Ang1e. The class should have a single data member of integer data type named degree to represent the angle in degrees whose value ranges from 0 to 359 degrees.
The class should have the following member functions:

- A default constructor that sets degree to 0 .
- A constructor that accepts an integer variable as an argument and sets degree to the value of the argument. If the argument value is not within the range, display an error message and set degree to 0 .
- A function setAngle that prompts the user to input the angle in degrees. If the user inputs a value beyond the range of $0-359$, then add or subtract sufficient multiples of 360 so that degree is within this range.
- A function getAngle that displays the angle in degrees.

The class should also have the following overloaded operators:

- Increment operator should increment degree by 1. If the value of degree becomes 360 , set degree to 0 .
- Decrement operator should decrement degree by 1 . If the value of degree become -1 , set degree to 359 .
- Addition operator should return an Angle object whose degree is the sum of the degree of two Angle objects.
- Subtraction operator should return an Ang1e object whose degree is the difference of the degree of two Angle objects.

Demonstrate the class in a program.

## 8. Date Class Modification

Modify the Date class in Programming Challenge 1 of Chapter 13. The new version should have the following overloaded operators:
++ Prefix and postfix increment operators. These operators should increment the object's day member.
-- Prefix and postfix decrement operators. These operators should decrement the object's day member.

- Subtraction operator. If one Date object is subtracted from another, the operator should give the number of days between the two dates. For example, if April 10, 2014 is subtracted from April 18, 2014, the result will be 8.
<< cout's stream insertion operator. This operator should cause the date to be displayed in the form
April 18, 2018
>> cin's stream extraction operator. This operator should prompt the user for a date to be stored in a Date object.

The class should detect the following conditions and handle them accordingly:

- When a date is set to the last day of the month and incremented, it should become the first day of the following month.
- When a date is set to December 31 and incremented, it should become January 1 of the following year.
- When a day is set to the first day of the month and decremented, it should become the last day of the previous month.
- When a date is set to January 1 and decremented, it should become December 31 of the previous year.
Demonstrate the class's capabilities in a simple program.
Input Validation: The overloaded >> operator should not accept invalid dates. For example, the date 13/45/2018 should not be accepted.

## 9. FeetInches Modification

Modify the FeetInches class discussed in this chapter so it overloads the following operators:
<=
$>=$
!=
Demonstrate the class's capabilities in a simple program.

## 10. Corporate Sales

A corporation has six divisions, each responsible for sales to different geographic locations. Design a DivSales class that keeps sales data for a division, with the following members:

- An array with four elements for holding four quarters of sales figures for the division.
- A private static variable for holding the total corporate sales for all divisions for the entire year.
- A member function that takes four arguments, each assumed to be the sales for a quarter. The value of the arguments should be copied into the array that holds the sales data. The total of the four arguments should be added to the static variable that holds the total yearly corporate sales.
- A function that takes an integer argument within the range of $0-3$. The argument is to be used as a subscript into the division quarterly sales array. The function should return the value of the array element with that subscript.
Write a program that creates an array of six DivSales objects. The program should ask the user to enter the sales for four quarters for each division. After the data are entered, the program should display a table showing the division sales for each quarter. The program should then display the total corporate sales for the year.
Input Validation: Only accept positive values for quarterly sales figures.

## 11. FeetInches Class Copy Constructor and multiply Function

Add a copy constructor to the FeetInches class. This constructor should accept a Feet Inches object as an argument. The constructor should assign to the feet attribute the value in the argument's feet attribute, and assign to the inches attribute the value in the argument's inches attribute. As a result, the new object will be a copy of the argument object.
Next, add a multiply member function to the FeetInches class. The multiply function should accept a FeetInches object as an argument. The argument object's feet and inches attributes will be multiplied by the calling object's feet and inches attributes, and a FeetInches object containing the result will be returned.

## 12. Annual Income Calculator

A certain person has earnings from both permanent and freelance jobs. Design a Salary class that stores his basic salary and other allowances ( $50 \%$ of the basic salary) for each month. Design a Freelance class that stores the number of jobs done in a year, and an array holding the income from each job. Include appropriate member functions in both the classes. Write a friend function to display his annual income. Demonstrate the classes and function in a program.

## 13. Carpet Calculator

The Westfield Carpet Company has asked you to write an application that calculates the price of carpeting for rectangular rooms. To calculate the price, you multiply the area of the floor (width times length) by the price per square foot of carpet. For example, the area of floor that is 12 feet long and 10 feet wide is 120 square feet. To cover that floor with carpet that costs $\$ 8$ per square foot would cost $\$ 960$. $(12 \times 10 \times 8=960$.)
First, you should create a class named RoomDimension that has two FeetInches objects as attributes: one for the length of the room, and one for the width. (You should use the version of the Feet Inches class you created in Programming Challenge 11 with the addition of a multiply member function. You can use this function to calculate the area of the room.) The RoomDimension class should have a member function that returns the area of the room as a Feet Inches object.
Next, you should create a RoomCarpet class that has a RoomDimension object as an attribute. It should also have an attribute for the cost of the carpet per square foot. The RoomCarpet class should have a member function that returns the total cost of the carpet.

Once you have written these classes, use them in an application that asks the user to enter the dimensions of a room and the price per square foot of the desired carpeting. The application should display the total cost of the carpet.

## 14. Cab Company

For this assignment, you will design a set of classes that work together to simulate a cab company. The company has only one cab that is shared between three drivers. The process is as follows:

1. A client calls the company and mentions their name and pickup location.
2. A random driver is assigned to the client and the driver takes the cab to pick up the client.
3. When the driver reaches the client, they mention their destination address. The driver starts driving.
4. Once the client has reached their destination, the number of drives for the driver is incremented.
5. When the driver arrives at the cab company, the driver exists and the number of drives for the car is incremented.

Design the following classes to simulate the process:

- The Cab class should simulate the cab. The class's responsibilities are:
- To know the current driver, the passenger, and the number of drives the car has done.
- A function getCurrentDestination() that returns the current destination of the cab. This is the pickup or destination address of the passenger, the cab company itself (after dropping off the passenger), or "nowhere" when the cab is waiting in the cab company for a new client.
- The Driver class should simulate the driver. The class's responsibilities are: - To know the name of the driver and the number of drives the driver has done.
- The Passenger class should simulate the passenger. The class's responsibilities are:
- To know the name of the passenger, their pickup location, and their destination.
- The CabCompany class should simulate the cab company. The class's responsibilities are:
- To manage the cab and the drivers.

A cab cannot be assigned to a new driver when there is a driver still using the car. Demonstrate the correctness of your classes in a program.

## 15. Computer Assembly

When buying a computer, you can either buy a prebuilt configuration or choose and assemble your own configuration, which is actually not that hard. It goes without saying that every part of the computer influences the overall speed and quality.
In real life, a computer consists of many different parts, but for this programming assignment, the three main parts are:

- the CPU (central processing unit)
- the GPU (graphics processing unit)
- the main memory (RAM)

Design separate classes for the CPU, GPU, and RAM. Each class should have a member that stores the relative quality of the part and the price in dollars. For the quality, you should use a scale from 1 to 10 , with 1 being very poor quality and 10 being excellent quality.
Each of the different classes also has specific member variables:

- The CPU has the clock speed and the number of cores.
- The GPU has the amount of dedicated video RAM and the bandwidth in MB/s.
- The RAM has the amount of RAM and the refresh rate (in MHz).

Each class should have accessor functions for each member variable, but only the price and the relative quality should have mutator functions. A product that once was premium quality may be moved to a lower scale because competition improved and thus the relative appreciation decreased.
Design a Computer class that should have member variables for the CPU, GPU, and RAM. Make sure that the constructor has arguments to initialize these values. Implement member functions to calculate the price (the sum of the prices of the individual parts $+10 \%$ extra for assembly) and the overall quality. The overall quality can be calculated by using a relative scale:

- the CPU accounts for $45 \%$ of the overall quality
- the GPU for $35 \%$
- the RAM for $20 \%$

Demonstrate your classes in a program.

## 15 Inheritance, Polymorphism, and Virtual Functions

## TOPICS

| 15.1 | What Is Inheritance? |
| :---: | :--- |
| 15.2 | Protected Members and Class <br> Access |
| 15.3 | Constructors and Destructors in <br> Base and Derived Classes |
| 15.4 | Redefining Base Class Functions |

### 15.5 Class Hierarchies

15.6 Polymorphism and Virtual Member Functions
15.7 Abstract Base Classes and Pure Virtual Functions
15.8 Multiple Inheritance

### 15.1 What Is Inheritance?

CONCEPT: Inheritance allows a new class to be based on an existing class. The new class automatically inherits all the member variables and functions, except the constructors and destructor, of the class it is based on. (In C++ 11, a class can optionally inherit some of the constructors of the class it is based on.)

## Generalization and Specialization

In the real-world, you can find many objects that are specialized versions of other more general objects. For example, the term "insect" describes a very general type of creature with numerous characteristics. Because grasshoppers and bumblebees are insects, they have all the general characteristics of an insect. In addition, they have special characteristics of their own. For example, the grasshopper has its jumping ability, and the bumblebee has its stinger. Grasshoppers and bumblebees are specialized versions of an insect. This is illustrated in Figure 15-1.

Figure 15-1 Specialized versions of an insect

In addition to the common insect characteristics, the bumblebee has its own unique characteristics such as the ability to sting.

In addition to the common insect characteristics, the grasshopper has its own unique characteristics such as the ability to jump.

## Inheritance and the "Is a" Relationship

When one object is a specialized version of another object, there is an "is a" relationship between them. For example, a grasshopper is an insect. Here are a few other examples of the "is a" relationship:

- A poodle is a dog.
- A car is a vehicle.
- A tree is a plant.
- A rectangle is a shape.
- A football player is an athlete.

When an "is a" relationship exists between classes, it means that the specialized class has all of the characteristics of the general class, plus additional characteristics that make it special. In object-oriented programming, inheritance is used to create an "is a" relationship between classes.

Inheritance involves a base class and a derived class. The base class is the general class and the derived class is the specialized class. The derived class is based on, or derived from, the base class. You can think of the base class as the parent, and the derived class as the child. This is illustrated in Figure 15-2.

Figure 15-2 Base class and derived class

The derived class inherits the member variables and member functions of the base class without any of them being rewritten. Furthermore, new member variables and functions may be added to the derived class to make it more specialized than the base class.

Let's look at an example of how inheritance can be used. Most teachers assign various graded activities for their students to complete. A graded activity can receive a numeric score such as $70,85,90$, and so on, and a letter grade such as A, B, C, D, or F. The following GradedActivity class is designed to hold the numeric score and letter grade of a graded activity. When a numeric score is stored by the class, it automatically determines the letter grade. (These files can be found in the Student Source Code Folder Chapter $15 \backslash$ GradedActivity Version 1.)

## Contents of GradedActivity.h (Version 1)

```
#ifndef GRADEDACTIVITY_H
#define GRADEDACTIVITY_H
// GradedActivity class declaration
class GradedActivity
{
private:
    double score; // To hold the numeric score
public:
    // Default constructor
    GradedActivity()
            { score = 0.0; }
    // Constructor
    GradedActivity(double s)
        { score = s; }
    // Mutator function
    void setScore(double s)
        { score = s; }
    // Accessor functions
    double getScore() const
        { return score; }
    char getLetterGrade() const;
};
#endif
```

## Contents of GradedActivity.cpp (Version 1)

```
#include "GradedActivity.h"
//*******************************************************
// Member function GradedActivity::getLetterGrade
//******************************************************
```

```
char GradedActivity::getLetterGrade() const
{
    char letterGrade; // To hold the letter grade
    if (score > 89)
        letterGrade = 'A';
    else if (score > 79)
        letterGrade = 'B';
    else if (score > 69)
        letterGrade = 'C';
    else if (score > 59)
            1etterGrade = 'D';
        else
            1etterGrade = 'F';
        return letterGrade;
}
```

The GradedActivity class has a default constructor that initializes the score member variable to 0.0 . A second constructor accepts an argument for score. The setScore member function also accepts an argument for the score variable, and the getLetterGrade member function returns the letter grade that corresponds to the value in score. Program 15-1 demonstrates the GradedActivity class. (This file can also be found in the Student Source Code Folder Chapter $15 \backslash$ GradedActivity Version 1.)

## Program 15-1

```
// This program demonstrates the GradedActivity class.
#include <iostream>
#include "GradedActivity.h"
using namespace std;
int main()
{
    double testScore; // To hold a test score
    // Create a GradedActivity object for the test.
    GradedActivity test;
    // Get a numeric test score from the user.
    cout << "Enter your numeric test score: ";
    cin >> testScore;
    // Store the numeric score in the test object.
    test.setScore(testScore);
    // Display the letter grade for the test.
    cout << "The grade for that test is "
            << test.getLetterGrade() << endl;
    return 0;
}
```

## Program Output with Example Input Shown in Bold

Enter your numeric test score: 89 Enter
The grade for that test is $B$

## Program Output with Different Example Input Shown in Bold

Enter your numeric test score: 75 Enter
The grade for that test is C
The GradedActivity class represents the general characteristics of a student's graded activity. Many different types of graded activities exist, however, such as quizzes, midterm exams, final exams, lab reports, essays, and so on. Because the numeric scores might be determined differently for each of these graded activities, we can create derived classes to handle each one. For example, the following code shows the Fina1Exam class, which is derived from the GradedActivity class. It has member variables for the number of questions on the exam (numQuestions), the number of points each question is worth (pointsEach), and the number of questions missed by the student (numMissed). These files can be found in the Student Source Code Folder Chapter $15 \backslash$ GradedActivity Version 1.

## Contents of Fina1Exam.h

```
#ifndef FINALEXAM_H
#define FINALEXAM_H
#include "GradedActivity.h"
class FinalExam : public GradedActivity
{
private:
    int numQuestions; // Number of questions
    double pointsEach; // Points for each question
    int numMissed; // Number of questions missed
public:
    // Default constructor
    FinalExam()
            { numQuestions = 0;
                pointsEach = 0.0;
                numMissed = 0; }
    // Constructor
    FinalExam(int questions, int missed)
            { set(questions, missed); }
    // Mutator function
    void set(int, int); // Defined in FinalExam.cpp
    // Accessor functions
    double getNumQuestions() const
        { return numQuestions; }
    double getPointsEach() const
        { return pointsEach; }
```

```
    int getNumMissed() const
    { return numMissed; }
};
#endif
```

## Contents of Fina1Exam. cpp

```
#include "FinalExam.h"
/|***********************************************************
// set function
// The parameters are the number of questions and the
// number of questions missed.
//**********************************************************
void FinalExam::set(int questions, int missed)
{
    double numericScore; // To hold the numeric score
    // Set the number of questions and number missed.
    numQuestions = questions;
    numMissed = missed;
    // Calculate the points for each question.
    pointsEach = 100.0 / numQuestions;
    // Calculate the numeric score for this exam.
    numericScore = 100.0 - (missed * pointsEach);
    // Call the inherited setScore function to set
    // the numeric score.
    setScore(numericScore);
}
```

The only new notation in this code is in line 5 of the FinalExam.h file, which reads
class FinalExam : public GradedActivity
This line indicates the name of the class being declared and the name of the base class it is derived from. FinalExam is the name of the class being declared, and GradedActivity is the name of the base class it inherits from.

If we want to express the relationship between the two classes, we can say a FinalExam is a GradedActivity.

The word public, which precedes the name of the base class in line 5 of the FinalExam.h file, is the base class access specification. It affects how the members of the base class are inherited by the derived class. When you create an object of a derived class, you can think of it as being built on top of an object of the base class. The members of the base class object become members of the derived class object. How the base class members appear in the derived class is determined by the base class access specification.

Although we will discuss this topic in more detail in the next section, let's see how it works in this example. The GradedActivity class has both private members and public members. The FinalExam class is derived from the GradedActivity class, using public access specification. This means that the public members of the GradedActivity class will become public members of the Fina1Exam class. The private members of the GradedActivity class cannot be accessed directly by code in the FinalExam class. Although the private members of the GradedActivity class are inherited, it's as though they are invisible to the code in the FinalExam class. They can only be accessed by the member functions of the GradedActivity class. Here is a list of the members of the Fina1Exam class:

Private Members:

```
int numQuestions Declared in the FinalExam class
double pointsEach
int numMissed
Declared in the FinalExam class Declared in the FinalExam class
```

Public Members:

```
Fina1Exam()
Fina1Exam(int, int)
set(int, int)
getNumQuestions()
getPointsEach()
getNumMissed()
setScore(doub1e)
getScore()
getLetterGrade()
```

Defined in the FinalExam class Defined in the FinalExam class Defined in the FinalExam class Defined in the FinalExam class Defined in the FinalExam class Defined in the FinalExam class Inherited from GradedActivity Inherited from GradedActivity Inherited from GradedActivity

The GradedActivity class has one private member, the variable score. Notice it is not listed as a member of the FinalExam class. It is still inherited by the derived class, but because it is a private member of the base class, only member functions of the base class may access it. It is truly private to the base class. Because the functions setScore, getScore, and getLetterGrade are public members of the base class, they also become public members of the derived class.

You will also notice the GradedActivity class constructors are not listed among the members of the Fina1Exam class. Although the base class constructors still exist, it makes sense that they are not members of the derived class because their purpose is to construct objects of the base class. In the next section, we discuss in more detail how base class constructors operate.
Let's take a closer look at the FinalExam class constructors. The default constructor appears in lines 13 through 16 of the FinalExam.h file. It simply assigns 0 to each of the class's member variables. Another constructor appears in lines 19 and 20. This constructor accepts two arguments: one for the number of questions on the exam, and one for the number of questions missed. This constructor merely passes those values as arguments to the set function.

The set function is defined in FinalExam.cpp. It accepts two arguments: the number of questions on the exam, and the number of questions missed by the student. In lines 14 and 15, these values are assigned to the numQuestions and numMissed member variables. In line 18 , the number of points for each question is calculated. In line 21 , the numeric test score is calculated. In line 25 , the last statement in the function reads:

```
setScore(numericScore);
```

This is a call to the setScore function. Although no setScore function appears in the Fina1Exam class, it is inherited from the GradedActivity class. Program 15-2 demonstrates the FinalExam class.

## Program 15-2

```
// This program demonstrates a base class and a derived class.
#include <iostream>
#include <iomanip>
#include "FinalExam.h"
using namespace std;
int main()
{
    int questions; // Number of questions on the exam
    int missed; // Number of questions missed by the student
    // Get the number of questions on the final exam.
    cout << "How many questions are on the final exam? ";
    cin >> questions;
    // Get the number of questions the student missed.
    cout << "How many questions did the student miss? ";
    cin >> missed;
    // Define a FinalExam object and initialize it with
    // the values entered.
    FinalExam test(questions, missed);
    // Display the test results.
    cout << setprecision(2);
    cout << "\nEach question counts " << test.getPointsEach()
        << " points.\n";
    cout << "The exam score is " << test.getScore() << endl;
    cout << "The exam grade is " << test.getLetterGrade() << endl;
    return 0;
}
```

## Program Output with Example Input Shown in Bold

How many questions are on the final exam? 20 Enter
How many questions did the student miss? 3 Enter
Each question counts 5 points.
The exam score is 85
The exam grade is B

Notice in lines 28 and 29, the public member functions of the GradedActivity class may be directly called by the test object:

```
cout << "The exam score is " << test.getScore() << endl;
cout << "The exam grade is " << test.getLetterGrade() << endl;
```

The getScore and getLetterGrade member functions are inherited as public members of the FinalExam class, so they may be accessed like any other public member.

Inheritance does not work in reverse. It is not possible for a base class to call a member function of a derived class. For example, the following classes will not compile in a program because the BadBase constructor attempts to call a function in its derived class:

```
class BadBase
{
        private:
            int x;
    public:
        BadBase() { x = getVal(); } // Error!
};
class Derived : public BadBase
{
    private:
        int y;
    public:
        Derived(int z) { y = z; }
        int getVal() { return y; }
};
```

## Checkpoint

15.1 Here is the first line of a class declaration. What is the name of the base class?
class Truck : public Vehicle
15.2 What is the name of the derived class in the following declaration line?

```
class Truck : public Vehicle
```

15.3 Suppose a program has the following class declarations:

```
class Shape
{
private:
    double area;
    public:
        void setArea(double a)
            { area = a; }
        doub1e getArea()
            { return area; }
    };
    class Circle : public Shape
    {
    private:
        double radius;
```

```
public:
    void setRadius(double r)
        { radius = r;
            setArea(3.14 * r * r); }
    double getRadius()
        { return radius; }
};
```

Answer the following questions concerning these classes:
A) When an object of the Circle class is created, what are its private members?
B) When an object of the Circle class is created, what are its public members?
C) What members of the Shape class are not accessible to member functions of the Circle class?

### 15.2 Protected Members and Class Access

CONCEPT: Protected members of a base class are like private members, but they may be accessed by derived classes. The base class access specification determines how private, public, and protected base class members are accessed when they are inherited by the derived classes.

Until now, you have used two access specifications within a class: private and public. C++ provides a third access specification, protected. Protected members of a base class are like private members, except they may be accessed by functions in a derived class. To the rest of the program, however, protected members are inaccessible.
The following code shows a modified version of the GradedActivity class declaration. The private member of the class has been made protected. This file can be found in the Student Source Code Folder Chapter 15\GradedActivity Version 2. The implementation file, GradedActivity.cpp has not changed, so it is not shown again in this example.

## Contents of GradedActivity.h (Version 2)

```
#ifndef GRADEDACTIVITY_H
#define GRADEDACTIVITY_H
// GradedActivity class declaration
class GradedActivity
{
protected:
    double score; // To hold the numeric score
public:
    // Default constructor
    GradedActivity()
        { score = 0.0; }
    // Constructor
    GradedActivity(double s)
        { score = s; }
```

18

```
    // Mutator function
    void setScore(double s)
        { score = s; }
    // Accessor functions
    double getScore() const
        { return score; }
    char getLetterGrade() const;
};
#endif
```

Now we will look at a modified version of the Fina1Exam class, which is derived from this version of the GradedActivity class. This version of the FinalExam class has a new member function named adjustScore. This function directly accesses the GradedActivity class's score member variable. If the content of the score variable has a fractional part of 0.5 or greater, the function rounds score up to the next whole number. The set function calls the adjustScore function after it calculates the numeric score. (These files are available in the Student Source Code Folder Chapter $15 \backslash$ GradedActivity Version 2.)

## Contents of Fina1Exam.h (Version 2)

```
#ifndef FINALEXAM_H
#define FINALEXAM_H
#include "GradedActivity.h"
class FinalExam : public GradedActivity
{
private:
    int numQuestions; // Number of questions
    double pointsEach; // Points for each question
    int numMissed; // Number of questions missed
public:
    // Defau7t constructor
    Fina1Exam()
        { numQuestions = 0;
                pointsEach = 0.0;
                numMissed = 0; }
    // Constructor
    Fina1Exam(int questions, int missed)
            { set(questions, missed); }
    // Mutator functions
    void set(int, int); // Defined in FinalExam.cpp
    void adjustScore(); // Defined in FinalExam.cpp
    // Accessor functions
    double getNumQuestions() const
        { return numQuestions; }
    double getPointsEach() const
        { return pointsEach; }
```

```
    int getNumMissed() const
    { return numMissed; }
};
#endif
```

## Contents of Fina1Exam. cpp (Version 2)

```
#include "FinalExam.h"
//*********************************************************
// set function
// The parameters are the number of questions and the
// number of questions missed.
//*********************************************************
void Fina1Exam::set(int questions, int missed)
{
    double numericScore; // To hold the numeric score
    // Set the number of questions and number missed.
    numQuestions = questions;
    numMissed = missed;
    // Calculate the points for each question.
    pointsEach = 100.0 / numQuestions;
    // Calculate the numeric score for this exam.
    numericScore = 100.0 - (missed * pointsEach);
    // Call the inherited setScore function to set
    // the numeric score.
    setScore(numericScore);
    // Cal1 the adjustScore function to adjust
    // the score.
    adjustScore();
}
//****************************************************************
// Definition of Test::adjustScore. If score is within
// 0.5 points of the next whole point, it rounds the score up *
// and recalculates the letter grade.
//*****************************************************************
void Fina1Exam::adjustScore()
{
    double fraction = score - static_cast<int>(score);
    if (fraction >= 0.5)
    {
        // Adjust the score variable in the GradedActivity class.
        score += (1.0 - fraction);
    }
}
```

Program 15-3 demonstrates these versions of the GradedActivity and Fina1Exam classes. (This file can be found in the Student Source Code Folder Chapter $15 \backslash$ GradedActivity Version 2.)

## Program 15-3

```
// This program demonstrates a base class with a
// protected member.
#include <iostream>
#include <iomanip>
#include "FinalExam.h"
using namespace std;
int main()
{
    int questions; // Number of questions on the exam
    int missed; /l Number of questions missed by the student
    // Get the number of questions on the final exam.
    cout << "How many questions are on the final exam? ";
    cin >> questions;
    // Get the number of questions the student missed.
    cout << "How many questions did the student miss? ";
    cin >> missed;
    // Define a FinalExam object and initialize it with
    // the values entered.
    Fina1Exam test(questions, missed);
    // Display the adjusted test results.
    cout << setprecision(2) << fixed;
    cout << "\nEach question counts "
        << test.getPointsEach() << " points.\n";
    cout << "The adjusted exam score is "
        << test.getScore() << endl;
    cout << "The exam grade is "
        << test.getLetterGrade() << endl;
    return 0;
}
```

## Program Output with Example Input Shown in Bold

How many questions are on the final exam? 16 Enter
How many questions did the student miss? 5 Enter
Each question counts 6.25 points.
The adjusted exam score is 69.00
The exam grade is D
The program works as planned. In the example run, the student missed five questions, which are worth 6.25 points each. The unadjusted score would be 68.75 . The score was adjusted to 69 .

## More about Base Class Access Specification

The first line of the FinalExam class declaration reads:

```
class FinalExam : public GradedActivity
```

This declaration gives public access specification to the base class. Recall from our earlier discussion that base class access specification affects how inherited base class members are accessed. Be careful not to confuse base class access specification with member access specification. Member access specification determines how members that are defined within the class are accessed. Base class access specification determines how inherited members are accessed.

When you create an object of a derived class, it inherits the members of the base class. The derived class can have its own private, protected, and public members, but what is the access specification of the inherited members? This is determined by the base class access specification. Table 15-1 summarizes how base class access specification affects the way that base class members are inherited.

Table 15-1 Base Class Access Specification

| Base Class Access <br> Specification | How Members of the Base Class Appear in the Derived Class |
| :--- | :--- |
| private | Private members of the base class are inaccessible to the derived class. <br> Protected members of the base class become private members of the <br> derived class. <br> Public members of the base class become private members of the derived <br> class. |
| protected | Private members of the base class are inaccessible to the derived class. <br> Protected members of the base class become protected members of the <br> derived class. <br> Public members of the base class become protected members of the derived <br> class. |
| public | Private members of the base class are inaccessible to the derived class. <br> Protected members of the base class become protected members of the <br> derived class. |
| Public members of the base class become public members of the derived class. |  |

As you can see from Table 15-1, class access specification gives you a great deal of flexibility in determining how base class members will appear in the derived class. Think of a base class's access specification as a filter that base class members must pass through when becoming inherited members of a derived class. This is illustrated in Figure 15-3.

NOTE: If the base class access specification is left out of a declaration, the default access specification is private. For example, in the following declaration, Grade is declared as a private base class:

```
class Test : Grade
```

Figure 15-3 Base class access specification

Base class members
How base class members appear

| private: $x$ <br> protected: $y$ <br> public: $z$ |
| :--- |

| private: $x$ <br> protected: <br> public: $z$ |
| :--- |

| private: $x$ <br> protected: $y$ <br> public: $z$ |
| :--- |

## Checkpoint

15.4 What is the difference between private members and protected members?
15.5 What is the difference between member access specification and class access specification?
15.6 Suppose a program has the following class declaration:

```
// Declaration of CheckPoint class.
class CheckPoint
{
    private:
        int a;
    protected:
        int b;
        int c;
        void setA(int x) { a = x;}
    public:
        void setB(int y) { b = y;}
        void setC(int z) { c = z;}
};
```

Answer the following questions regarding the class:
A) Suppose another class, Quiz, is derived from the CheckPoint class. Here is the first line of its declaration:

```
class Quiz : private CheckPoint
```

Indicate whether each member of the CheckPoint class is private, protected, public, or inaccessible:

```
a
b
c
setA
setB
setC
```

B) Suppose the Quiz class, derived from the CheckPoint class, is declared as

```
class Quiz : protected Checkpoint
```

Indicate whether each member of the CheckPoint class is private, protected, public, or inaccessible:

```
a
b
c
setA
setB
setC
```

C) Suppose the Quiz class, derived from the CheckPoint class, is declared as
class Quiz : public Checkpoint
Indicate whether each member of the CheckPoint class is private, protected, public, or inaccessible:

```
a
b
c
setA
setB
setC
```

D) Suppose the Quiz class, derived from the CheckPoint class, is declared as
class Quiz : Checkpoint
Is the CheckPoint class a private, public, or protected base class?

### 15.3 Constructors and Destructors in Base and Derived Classes

CONCEPT: The base class's constructor is called before the derived class's constructor. The destructors are called in reverse order, with the derived class's destructor being called first.

In inheritance, the base class constructor is called before the derived class constructor. Destructors are called in reverse order. Program 15-4 shows a simple set of demonstration classes, each with a default constructor and a destructor. The DerivedClass class is derived from the BaseClass class. Messages are displayed by the constructors and destructors to demonstrate when each is called.

## Program 15-4

```
// This program demonstrates the order in which base and
// derived class constructors and destructors are called.
#include <iostream>
using namespace std;
|/********************************
// BaseClass declaration *
//*********************************
```

```
class BaseClass
{
public:
    BaseClass() // Constructor
        { cout << "This is the BaseClass constructor.\n"; }
    ~BaseClass() // Destructor
        { cout << "This is the BaseClass destructor.\n"; }
};
//********************************
// DerivedClass declaration
//********************************
class DerivedClass : public BaseClass
{
public:
    DerivedClass() // Constructor
        { cout << "This is the DerivedClass constructor.\n"; }
    ~DerivedClass() // Destructor
        { cout << "This is the DerivedClass destructor.\n"; }
};
//*********************************
// main function
//********************************
int main()
{
    cout << "We will now define a DerivedClass object.\n";
    DerivedClass object;
    cout << "The program is now going to end.\n";
    return 0;
}
```

## Program Output

We will now define a DerivedClass object.
This is the BaseClass constructor.
This is the DerivedClass constructor.
The program is now going to end.
This is the DerivedClass destructor.
This is the BaseClass destructor.

## Passing Arguments to Base Class Constructors

In Program 15-4, both the base class and derived class have default constructors, which are called automatically. But what if the base class's constructor takes arguments? What if there is more than one constructor in the base class? The answer to these questions is to let the derived class constructor pass arguments to the base class constructor. For example, consider the following class:

## Contents of Rectangle.h

```
#ifndef RECTANGLE_H
#define RECTANGLE_H
class Rectangle
{
private:
    double width;
    double length;
public:
    // Default constructor
    Rectangle()
            { width = 0.0;
                length = 0.0; }
    // Constructor #2
    Rectangle(double w, double len)
            { width = w;
                1ength = 1en; }
    double getWidth() const
            { return width; }
    double getLength() const
            { return length; }
    double getArea() const
        { return width * length; }
};
#endif
```

This class is designed to hold data about a rectangle. It specifies two constructors. The default constructor, in lines 11 through 13 , simply initializes the width and length member variables to 0.0 . The second constructor, in lines 16 through 18 , takes two arguments, which are assigned to the width and length member variables. Now let's look at a class that is derived from the Rectangle class:

## Contents of Box.h

```
#ifndef BOX_H
#define BOX_H
#include "Rectangle.h"
class Box : public Rectangle
{
protected:
    double height;
    double volume;
pub1ic:
    // Default constructor
    Box() : Rectangle()
    { height = 0.0; volume = 0.0; }
```

14

```
    // Constructor #2
    Box(double w, double len, double h) : Rectangle(w, len)
    { height = h;
        volume = getArea() * h; }
    double getHeight() const
    { return height; }
    double getVolume() const
    { return volume; }
};
#endif
```

The Box class is designed to hold data about boxes, which not only have a length and width, but a height and volume as well. Look at line 12, which is the first line of the Box class's default constructor:

```
Box() : Rectangle()
```

Notice the added notation in the header of the constructor. A colon is placed after the derived class constructor's parentheses, followed by a function call to a base class constructor. In this case, the base class's default constructor is being called. When this Box class constructor executes, it will first call the Rectangle class's default constructor. This is illustrated here:

The general format of this type of constructor declaration is

```
ClassName::ClassName(ParameterList) : BaseClassName(ArgumentList)
```

You can also pass arguments to the base class constructor, as shown in the Box class's second constructor. Look at line 16:

```
Box(double w, double len, double h) : Rectangle(w, len)
```

This Box class constructor has three parameters: w, len, and h. Notice the Rectangle class's constructor is called, and the $w$ and len parameters are passed as arguments. This causes the Rectangle class's second constructor to be called.

You only write this notation in the definition of a constructor, not in a prototype. In this example, the derived class constructor is written inline (inside the class declaration), so the notation that contains the call to the base class constructor appears there. If the constructor were defined outside the class, the notation would appear in the function header. For example, the Box class could appear as follows:

```
class Box : public Rectangle
{
protected:
    double height;
    double volume;
public:
        // Default constructor
        Box() : Rectangle()
            { height = 0.0; volume = 0.0; }
        // Constructor #2
        Box(doub1e, doub1e, doub1e);
        double getHeight() const
            { return height; }
        double getVolume() const
            { return volume; }
};
// Box class constructor #2
Box::Box(double w, double len, double h) : Rectangle(w, len)
{
    height = h;
    volume = getArea() * h;
}
```

The base class constructor is always executed before the derived class constructor. When the Rectangle constructor finishes, the Box constructor is then executed.
Any literal value or variable that is in scope may be used as an argument to the derived class constructor. Usually, one or more of the arguments passed to the derived class constructor are, in turn, passed to the base class constructor. The values that may be used as base class constructor arguments are as follows:

- Derived class constructor parameters
- Literal values
- Global variables that are accessible to the file containing the derived class constructor definition
- Expressions involving any of these items

Program 15-5 shows the Rectangle and Box classes in use.

## Program 15-5

```
// This program demonstrates passing arguments to a base
// class constructor.
#include <iostream>
#include "Box.h"
using namespace std;
```

6

```
int main()
{
    double boxWidth; // To hold the box's width
    double boxLength; // To hold the box's length
    double boxHeight; // To hold the box's height
    // Get the width, length, and height from the user.
    cout << "Enter the dimensions of a box:\n";
    cout << "Width: ";
    cin >> boxWidth;
    cout << "Length: ";
    cin >> boxLength;
    cout << "Height: ";
    cin >> boxHeight;
    // Define a Box object.
    Box myBox(boxWidth, boxLength, boxHeight);
    // Display the Box object's properties.
    cout << "Here are the box's properties:\n";
    cout << "Width: " << myBox.getWidth() << endl;
    cout << "Length: " << myBox.getLength() << endl;
    cout << "Height: " << myBox.getHeight() << endl;
    cout << "Base area: " << myBox.getArea() << endl;
    cout << "Volume: " << myBox.getVolume() << endl;
    return 0;
}
```

## Program Output with Example Input Shown in Bold

Enter the dimensions of a box:
Width: 10 Enter
Length: 15 Enter
Height: 12 Enter
Here are the box's properties:
Width: 10
Length: 15
Height: 12
Base area: 150
Volume: 1800

NOTE: If the base class has no default constructor, then the derived class must have a constructor that calls one of the base class constructors.

## In the Spotlight:

## The Automobile, Car, Truck, and SUV Classes

Suppose we are developing a program that a car dealership can use to manage its inventory of used cars. The dealership's inventory includes three types of automobiles: cars, pickup trucks, and sport-utility vehicles (SUVs). Regardless of the type, the dealership keeps the following data about each automobile:

- Make
- Year model
- Mileage
- Price

Each type of vehicle that is kept in inventory has these general characteristics, plus its own specialized characteristics. For cars, the dealership keeps the following additional data:

- Number of doors (2 or 4)

For pickup trucks, the dealership keeps the following additional data:

- Drive type (two-wheel drive or four-wheel drive)

And, for SUVs, the dealership keeps the following additional data:

- Passenger capacity

In designing this program, one approach would be to write the following three classes:

- A Car class with attributes for the make, year model, mileage, price, and number of doors.
- A Truck class with attributes for the make, year model, mileage, price, and drive type.
- An SUV class with attributes for the make, year model, mileage, price, and passenger capacity.
This would be an inefficient approach, however, because all three classes have a large number of common data attributes. As a result, the classes would contain a lot of duplicated code. In addition, if we discover later we need to add more common attributes, we would have to modify all three classes.

A better approach would be to write an Automobile base class to hold all the general data about an automobile, then write derived classes for each specific type of automobile. The following code shows the Automobile class. (This file can be found in the Student Source Code Folder Chapter 15\Automobile.)

## Contents of Automobile.h

```
#ifndef AUTOMOBILE_H
#define AUTOMOBILE_H
#include <string>
using namespace std;
// The Automobile class holds general data
// about an automobile in inventory.
class Automobile
{
```

```
private:
    string make; // The auto's make
    int model; // The auto's year model
    int mileage; // The auto's mileage
    double price; // The auto's price
public:
    // Default constructor
    Automobile()
    { make = "";
        model = 0;
        mileage = 0;
        price = 0.0; }
    // Constructor
    Automobile(string autoMake, int autoMode1,
            int autoMileage, double autoPrice)
    { make = autoMake;
        model = autoMode1;
        mileage = autoMileage;
        price = autoPrice; }
    // Accessors
    string getMake() const
    { return make; }
    int getModel() const
    { return model; }
    int getMileage() const
    { return mileage; }
    double getPrice() const
    { return price; }
};
#endif
```

Notice the class has a default constructor in lines 18 and 22, and a constructor that accepts arguments for all of the class's attributes in lines 25 through 30 . The Automobile class is a complete class from which we can create objects. If we wish, we can write a program that creates instances of the Automobile class. However, the Automobile class holds only general data about an automobile. It does not hold any of the specific pieces of data that the dealership wants to keep about cars, pickup trucks, and SUVs. To hold data about those specific types of automobiles, we will write derived classes that inherit from the Automobile class. The following shows the code for the Car class. (This file is available in the Student Source Code Folder Chapter 15\Automobile.)

## Contents of Car.h

```
#ifndef CAR_H
#define CAR_H
#include "Automobile.h"
#include <string>
using namespace std;
```

```
// The Car class represents a car.
class Car : public Automobile
{
private:
    int doors;
pub1ic:
    // Default constructor
    Car() : Automobile()
    { doors = 0;}
    // Constructor #2
    Car(string carMake, int carMode1, int carMileage,
            double carPrice, int carDoors) :
            Automobile(carMake, carMode1, carMileage, carPrice)
    { doors = carDoors; }
    // Accessor for doors attribute
    int getDoors()
    {return doors;}
};
#endif
```

The Car class defines a doors attribute in line 11 to hold the car's number of doors. The class has a default constructor in lines 15 and 16 that sets the doors attribute to 0 . Notice in line 15 the default constructor calls the Automobile class's default constructor, which initializes all of the inherited attributes to their default values.

The Car class also has an overloaded constructor, in lines 19 through 22, that accepts arguments for the car's make, model, mileage, price, and number of doors. Line 21 calls the Automobile class's constructor, passing the make, model, mileage, and price as arguments. Line 22 sets the value of the doors attribute.
Now let's look at the Truck class, which also inherits from the Automobile class. (This file is available in the Student Source Code Folder Chapter 15\Automobile.)

## Contents of Truck.h

```
#ifndef TRUCK_H
#define TRUCK_H
#include "Automobile.h"
#include <string>
using namespace std;
// The Truck class represents a truck.
class Truck : public Automobile
{
private:
    string driveType;
public:
    // Default constructor
    Truck() : Automobile()
    { driveType = ""; }
```

```
    // Constructor #2
    Truck(string truckMake, int truckModel, int truckMileage,
        double truckPrice, string truckDriveType) :
        Automobile(truckMake, truckModel, truckMileage, truckPrice)
    { driveType = truckDriveType; }
    // Accessor for driveType attribute
    string getDriveType()
    { return driveType; }
};
#endif
```

The Truck class defines a driveType attribute in line 11 to hold a string describing the truck's drive type. The class has a default constructor in lines 15 and 16 that sets the driveType attribute to an empty string. Notice in line 15 the default constructor calls the Automobile class's default constructor, which initializes all of the inherited attributes to their default values.

The Truck class also has an overloaded constructor, in lines 19 through 22 , that accepts arguments for the truck's make, model, mileage, price, and drive type. Line 21 calls the Automobile class's constructor, passing the make, model, mileage, and price as arguments. Line 22 sets the value of the driveType attribute.

Now let's look at the SUV class, which also inherits from the Automobile class. (This file can be found in the Student Source Code Folder Chapter $15 \backslash$ Automobile.)

## Contents of SUV .h

```
#ifndef SUV_H
#define SUV_H
#include "Automobile.h"
#include <string>
using namespace std;
// The SUV class represents a SUV.
class SUV : public Automobile
{
private:
    int passengers;
pub1ic:
        // Default constructor
        SUV() : Automobile()
        { passengers = 0; }
    // Constructor #2
    SUV(string SUVMake, int SUVModel, int SUVMileage,
            double SUVPrice, int SUVPassengers) :
            Automobile(SUVMake, SUVMode1, SUVMileage, SUVPrice)
        { passengers = SUVPassengers; }
        // Accessor for passengers attribute
        int getPassengers()
        { return passengers; }
};
#endif
```

The SUV class defines a passengers attribute in line 11 to hold the number of passengers that the vehicle can accommodate. The class has a default constructor in lines 15 and 16 that sets the passengers attribute to 0 . Notice in line 15 the default constructor calls the Automobile class's default constructor, which initializes all of the inherited attributes to their default values.

The SUV class also has an overloaded constructor, in lines 19 through 22, that accepts arguments for the SUV's make, model, mileage, price, and number of passengers. Line 21 calls the Automobile class's constructor, passing the make, model, mileage, and price as arguments. Line 22 sets the value of the passengers attribute.
Program 15-6 demonstrates each of the derived classes. It creates a Car object, a Truck object, and an SUV object. (This file can be found in the Student Source Code Folder Chapter 15\Automobile.)

## Program 15-6

```
// This program demonstrates the Car, Truck, and SUV
// classes that are derived from the Automobile class.
#include <iostream>
#include <iomanip>
#include "Car.h"
#include "Truck.h"
#include "SUV.h"
using namespace std;
int main()
{
    // Create a Car object for a used 2007 BMW with
    // 50,000 miles, priced at $15,000, with 4 doors.
    Car car("BMW", 2007, 50000, 15000.0, 4);
    // Create a Truck object for a used 2006 Toyota
    // pickup with 40,000 miles, priced at $12,000,
    // with 4-wheel drive.
    Truck truck("Toyota", 2006, 40000, 12000.0, "4WD");
    // Create an SUV object for a used 2005 Volvo
    // with 30,000 miles, priced at $18,000, with
    // 5 passenger capacity.
    SUV suv("Volvo", 2005, 30000, 18000.0, 5);
    // Display the automobiles we have in inventory.
    cout << fixed << showpoint << setprecision(2);
    cout << "We have the following car in inventory:\n"
        << car.getModel() << " " << car.getMake()
        << " with " << car.getDoors() << " doors and "
        << car.getMileage() << " miles.\nPrice: $"
        << car.getPrice() << endl << endl;
```

```
34
35
36
3 7
38
39
4 0
4 1
4 2
4 3
4 4
4 5
4 6
    return 0;
}
```

## Program Output

We have the following car in inventory:
2007 BMW with 4 doors and 50000 miles.
Price: \$15000.00
We have the following truck in inventory:
2006 Toyota with 4WD drive type and 40000 miles.
Price: \$12000.00
We have the following SUV in inventory:
2005 Volvo with 30000 miles and 5 passenger capacity.
Price: \$18000.00

## Constructor Inheritance

C++ 11 provides a way for a derived class to inherit some of the base class's constructors. The constructors that cannot be inherited are the default constructor, the copy constructor, and the move constructor. Any other constructors in the base class can be inherited.

Constructor inheritance can be helpful in situations where the derived class's constructors simply invoke the base class's constructors. For example, look at the following classes:

```
class MyBase
{
private:
    int ival;
    double dval;
public:
    MyBase(int i)
    { ival = i; }
    MyBase(double d)
    { dval = d; }
};
```

```
class MyDerived : MyBase
{
pub1ic:
    MyDerived(int i) : MyBase(i)
    {}
    MyDerived(double d) : MyBase(d)
    {}
};
```

In this code, the MyDerived (int i) constructor simply calls the MyBase (int i) constructor, and the MyDerived (double d) constructor simply calls the MyBase (double d) constructor. In C++ 11, we rewrite the MyDerived class as follows, and achieve the same result:

```
class MyDerived : MyBase
{
    using MyBase::MyBase;
};
```

The using statement causes the MyDerived class to inherit the MyBase class's constructors. As a result, we can invoke the MyBase class's constructors when we instantiate the MyDerived class.

```
MyDerived d1(22); // Calls the MyBase(int i) constructor
MyDerived d2(3.14); // Calls the MyBase(double d) constructor
```

You can write the using statement anywhere in the derived class. The general format of the using statement in a derived class is

```
using BaseClassName::BaseClassName;
```

A derived class can have its own constructors, and inherit constructors from the base class.
Here is an example:

```
class Derived : Base
{
private:
    string str;
public:
    using Base::Base;
    Derived(string s) : Base(0)
    { str = s; }
};
```

Keep in mind, however, if a derived class constructor has the same parameter list as a base class constructor, the base class constructor will not be inherited.

## Checkpoint

15.7 What will the following program display?

```
#include <iostream>
```

using namespace std;

```
class Sky
{
public:
    Sky()
        { cout << "Entering the sky.\n"; }
    ~Sky()
        { cout << "Leaving the sky.\n"; }
};
class Ground : public Sky
{
public:
    Ground()
            { cout << "Entering the Ground.\n"; }
    ~Ground()
        { cout << "Leaving the Ground.\n"; }
};
int main()
{
    Ground object;
    return 0;
}
```

15.8 What will the following program display?

```
#include <iostream>
using namespace std;
class Sky
{
public:
        Sky()
            { cout << "Entering the sky.\n"; }
        Sky(string color)
            { cout << "The sky is " << color << endl; }
        ~Sky()
            { cout << "Leaving the sky.\n"; }
};
class Ground : public Sky
{
public:
        Ground()
            { cout << "Entering the Ground.\n"; }
        Ground(string c1, string c2) : Sky(c1)
            { cout << "The ground is " << c2 << endl; }
        ~Ground()
            { cout << "Leaving the Ground.\n"; }
};
int main()
{
        Ground object;
        return 0;
}
```

### 15.4 Redefining Base Class Functions

CONCEPT: A base class member function may be redefined in a derived class.

VideoNote
Redefining
a Base Class Function in a Derived Class

Inheritance is commonly used to extend a class, or to give it additional capabilities. Sometimes it may be helpful to overload a base class function with a function of the same name in the derived class. For example, recall the GradedActivity class that was presented earlier in this chapter:

```
class GradedActivity
{
protected:
    char letter; // To hold the letter grade
    double score; // To hold the numeric score
    void determineGrade(); // Determines the letter grade
public:
    // Default constructor
    GradedActivity()
        { letter = ' '; score = 0.0; }
    // Mutator function
    void setScore(double s)
            { score = s;
                determineGrade(); }
    // Accessor functions
    double getScore() const
        { return score; }
    char getLetterGrade() const
        { return letter; }
};
```

This class holds a numeric score and determines a letter grade based on that score. The setScore member function stores a value in score, then calls the determineGrade member function to determine the letter grade.

Suppose a teacher wants to "curve" a numeric score before the letter grade is determined. For example, Dr. Harrison determines that in order to curve the grades in her class, she must multiply each student's score by a certain percentage. This gives an adjusted score, which is used to determine the letter grade.

The following CurvedActivity class is derived from the GradedActivity class. It multiplies the numeric score by a percentage, and passes that value as an argument to the base class's setScore function. (This file can be found in the Student Source Code Folder Chapter 15\CurvedActivity.)

## Contents of CurvedActivity.h

```
#ifndef CURVEDACTIVITY_H
#define CURVEDACTIVITY_H
#include "GradedActivity.h"
class CurvedActivity : public GradedActivity
{
protected:
    double rawScore; // Unadjusted score
    double percentage; // Curve percentage
public:
    // Default constructor
    CurvedActivity() : GradedActivity()
        { rawScore = 0.0; percentage = 0.0; }
    // Mutator functions
    void setScore(double s)
        { rawScore = s;
                GradedActivity::setScore(rawScore * percentage); }
    void setPercentage(double c)
        { percentage = c; }
    // Accessor functions
    double getPercentage() const
        { return percentage; }
    double getRawScore() const
        { return rawScore; }
};
#endif
```

This CurvedActivity class has the following member variables:

- rawScore This variable holds the student's unadjusted score.
- percentage This variable holds the value that the unadjusted score must be multiplied by to get the curved score.

It also has the following member functions:

- A default constructor that calls the GradedActivity default constructor, then sets rawScore and percentage to 0.0 .
- setScore
- setPercentage
- getPercentage
- getRawScore

This function accepts an argument that is the student's unadjusted score. The function stores the argument in the rawScore variable, then passes rawScore * percentage as an argument to the base class's setScore function.
This function stores a value in the percentage variable. This function returns the value in the percentage variable. This function returns the value in the rawScore variable.

NOTE: Although we are not using the CurvedActivity class as a base class, it still has a protected member section. This is because we might want to use the CurvedActivity class itself as a base class, as you will see in the next section.

Notice the CurvedActivity class has a setScore member function. This function has the same name as one of the base class member functions. When a derived class's member function has the same name as a base class member function, it is said the derived class function redefines the base class function. When an object of the derived class calls the function, it calls the derived class's version of the function.

There is a distinction between redefining a function and overloading a function. An overloaded function is one with the same name as one or more other functions, but with a different parameter list. The compiler uses the arguments passed to the function to tell which version to call. Overloading can take place with regular functions that are not members of a class. Overloading can also take place inside a class when two or more member functions of the same class have the same name. These member functions must have different parameter lists for the compiler to tell them apart in function calls.

Redefining happens when a derived class has a function with the same name as a base class function. The parameter lists of the two functions can be the same because the derived class function is always called by objects of the derived class type.

Let's continue our look at the CurvedActivity class. Here is the setScore member function:

```
void setScore(double s)
    { rawScore = s;
        GradedActivity::setScore(rawScore * percentage); }
```

This function accepts an argument that should be the student's unadjusted numeric score, into the parameter s. This value is stored in the rawScore variable. Then, the following statement is executed:

```
GradedActivity::setScore(rawScore * percentage);
```

This statement calls the base class's version of the setScore function with the expression rawScore * percentage passed as an argument. Notice the name of the base class and the scope resolution operator precede the name of the function. This specifies that the base class's version of the setScore function is being called. A derived class function may call a base class function of the same name using this notation, which takes this form:

```
BaseClassName::functionName(ArgumentList);
```

Program 15-7 shows the GradedActivity and CurvedActivity classes used in a complete program. (This file is available in the Student Source Code Folder Chapter 15\CurvedActivity.)

## Program 15-7

```
// This program demonstrates a class that redefines
// a base class function.
#include <iostream>
#include <iomanip>
#include "CurvedActivity.h"
using namespace std;
int main()
{
    double numericScore; // To hold the numeric score
    double percentage; // To hold curve percentage
    // Define a CurvedActivity object.
    CurvedActivity exam;
    // Get the unadjusted score.
    cout << "Enter the student's raw numeric score: ";
    cin >> numericScore;
    // Get the curve percentage.
    cout << "Enter the curve percentage for this student: ";
    cin >> percentage;
    // Send the values to the exam object.
    exam.setPercentage(percentage);
    exam.setScore(numericScore);
    // Display the grade data.
    cout << fixed << setprecision(2);
    cout << "The raw score is "
        << exam.getRawScore() << endl;
    cout << "The curved score is "
        << exam.getScore() << endl;
        cout << "The curved grade is "
        << exam.getLetterGrade() << endl;
    return 0;
}
```

## Program Output with Example Input Shown in Bold

Enter the student's raw numeric score: 87 Enter
Enter the curve percentage for this student: 1.06 Enter
The raw score is 87.00
The curved score is 92.22
The curved grade is A

It is important to note even though a derived class may redefine a function in the base class, objects that are defined of the base class type still call the base class version of the function. This is demonstrated in Program 15-8.

## Program 15-8

```
// This program demonstrates that when a derived class function
// overrides a class function, objects of the base class
// still call the base class version of the function.
#include <iostream>
using namespace std;
class BaseClass
{
public:
    void showMessage()
        { cout << "This is the Base class.\n";}
};
class DerivedClass : public BaseClass
{
public:
    void showMessage()
            { cout << "This is the Derived class.\n"; }
};
int main()
{
        BaseClass b;
    DerivedClass d;
    b.showMessage();
    d.showMessage();
        return 0;
}
```

## Program Output

This is the Base class.
This is the Derived class.

In Program 15-8, a class named BaseClass is declared with a member function named showMessage. A class named DerivedClass is then declared, also with a showMessage member function. As their names imply, DerivedClass is derived from BaseClass. Two objects, $b$ and $d$, are defined in function main. The object $b$ is a BaseClass object, and d is a DerivedClass object. When b is used to call the showMessage function, it is the BaseClass version that is executed. Likewise, when d is used to call showMessage, the DerivedClass version is used.

### 15.5 Class Hierarchies

CONCEPT: A base class can also be derived from another class.
Sometimes it is desirable to establish a hierarchy of classes in which one class inherits from a second class, which in turn inherits from a third class, as illustrated by Figure 15-4. In some cases, the inheritance of classes goes on for many layers.

Figure 15-4 Class hierarchy

In Figure 15-4, Cl ass C inherits Cl assB's members, including the ones that Cl ass B inherited from ClassA. Let's look at an example of such a chain of inheritance. Consider the following PassFailActivity class, which inherits from the GradedActivity class. The class is intended to determine a letter grade of ' P ' for passing, or ' F ' for failing. (This file can be found in the Student Source Code Folder Chapter 15\PassFailActivity.)

## Contents of PassFailActivity.h

```
#ifndef PASSFAILACTIVITY_H
#define PASSFAILACTIVITY_H
#include "GradedActivity.h"
class PassFailActivity : public GradedActivity
{
protected:
    double minPassingScore; // Minimum passing score.
public:
    // Default constructor
    PassFailActivity() : GradedActivity()
        { minPassingScore = 0.0; }
```

```
1 3
14 // Constructor
1 5 ~ P a s s F a i l A c t i v i t y ( d o u b l e ~ m p s ) ~ : ~ G r a d e d A c t i v i t y ( )
16
1 7
18
19
20
21
22
23
24
25
26
27 };
28 #endif
```

The PassFailActivity class has a private member variable named minPassingScore. This variable holds the minimum passing score for an activity. The default constructor, in lines 11 and 12 , sets minPassingScore to 0.0 . An overloaded constructor in lines 15 and 16 accepts a double argument that is the minimum passing grade for the activity. This value is stored in the minPassingScore variable. The getLetterGrade member function is defined in the following PassFailActivity.cpp file. (This file can be found in the Student Source Code Folder Chapter 15\PassFailActivity.)

## Contents of PassFailActivity.cpp

```
#include "PassFailActivity.h"
//******************************************************
// Member function PassFailActivity::getLetterGrade *
// This function returns 'P' if the score is passing, *
// otherwise it returns 'F'.
|/*********************************************************
char PassFailActivity::getLetterGrade() const
{
    char letterGrade;
    if (score >= minPassingScore)
            letterGrade = 'P';
        else
            letterGrade = 'F';
        return letterGrade;
}
```

This getLetterGrade member function redefines the getLetterGrade member function of GradedActivity class. This version of the function returns a grade of ' $P$ ' if the numeric score is greater than or equal to minPassingScore. Otherwise, the function returns a grade of ' $F$ '.

The PassFailActivity class represents the general characteristics of a student's pass-orfail activity. There might be numerous types of pass-or-fail activities, however. Suppose we need a more specialized class, such as one that determines a student's grade for a pass-orfail exam. The following PassFai1Exam class is an example. This class is derived from the PassFailActivity class. It inherits all of the members of PassFailActivity, including the ones that PassFailActivity inherits from GradedActivity. The PassFailExam class calculates the number of points that each question on the exam is worth, as well as the student's numeric score. (These files are available in the Student Source Code Folder Chapter $15 \backslash$ PassFailActivity.)

## Contents of PassFailExam.h

```
#ifndef PASSFAILEXAM_H
#define PASSFAILEXAM_H
#include "PassFailActivity.h"
class PassFailExam : public PassFailActivity
{
private:
    int numQuestions; // Number of questions
    double pointsEach; // Points for each question
    int numMissed; // Number of questions missed
public:
    // Default constructor
    PassFai1Exam() : PassFailActivity()
        { numQuestions = 0;
            pointsEach = 0.0;
            numMissed = 0; }
    // Constructor
    PassFai1Exam(int questions, int missed, double mps) :
        PassFailActivity(mps)
        { set(questions, missed); }
    // Mutator function
    void set(int, int); // Defined in PassFailExam.cpp
    // Accessor functions
    double getNumQuestions() const
        { return numQuestions; }
    double getPointsEach() const
        { return pointsEach; }
    int getNumMissed() const
        { return numMissed; }
};
#endif
```

## Contents of PassFai1Exam.cpp

```
#include "PassFailExam.h"
|/********************************************************
// set function
// The parameters are the number of questions and the *
// number of questions missed.
|/***********************************************************
void PassFailExam::set(int questions, int missed)
{
    double numericScore; // To hold the numeric score
    // Set the number of questions and number missed.
    numQuestions = questions;
    numMissed = missed;
    // Calculate the points for each question.
    pointsEach = 100.0 / numQuestions;
    // Calculate the numeric score for this exam.
    numericScore = 100.0 - (missed * pointsEach);
    // Call the inherited setScore function to set
    // the numeric score.
    setScore(numericScore);
}
```

The PassFailExam class inherits all of the PassFailActivity class's members, including the ones that PassFailActivity inherited from GradedActivity. Because the public base class access specification is used, all of the protected members of PassFailActivity become protected members of PassFailExam, and all of the public members of PassFailActivity become public members of PassFailExam. Table 15-2 lists all of the member variables of the PassFailExam class, and Table 15-3 lists all the member functions. These include the members that were inherited from the base classes.

Table 15-2 Member Variables of the PassFai1Exam Class

| Member Variable | Access | Inherited? |
| :--- | :--- | :--- |
| numQuestions | protected | No |
| pointsEach | protected | No |
| numMissed | protected | No |
| minPassingScore | protected | Yes, from PassFailActivity |
| score | protected | Yes, from PassFailActivity, which inherited it from <br> GradedActivity |

Table 15-3 Member Functions of the PassFai1Exam Class

| Member Function | Access | Inherited? |
| :--- | :--- | :--- |
| set | public | No |
| getNumQuestions | public | No |
| getPointsEach | public | No |
| getNumMissed | public | No |
| setMinPassingScore | public | Yes, from PassFailActivity |
| getMinPassingScore | public | Yes, from PassFailActivity |
| getLetterGrade | public | Yes, from PassFailActivity |
| setScore | public | Yes, from PassFailActivity, which inherited it from |
| getScore | public | GradedActivity <br>  |
|  |  | YradedActivity |

Program 15-9 demonstrates the PassFai1Exam class. This file can be found in the student source code folder Chapter 15\PassFailActivity.

## Program 15-9

// This program demonstrates the PassFailExam class.
\#include <iostream>
\#include <iomanip>
\#include "PassFailExam.h"
using namespace std;
int main()
\{

```
    int questions; // Number of questions
    int missed; // Number of questions missed
    double minPassing; // The minimum passing score
    // Get the number of questions on the exam.
    cout << "How many questions are on the exam? ";
    cin >> questions;
    // Get the number of questions the student missed.
    cout << "How many questions did the student miss? ";
    cin >> missed;
    // Get the minimum passing score.
    cout << "Enter the minimum passing score for this test: ";
    cin >> minPassing;
    // Define a PassFailExam object.
    PassFailExam exam(questions, missed, minPassing);
```

## Program 15-9 (continued)

```
    // Display the test results.
    cout << fixed << setprecision(1);
    cout << "\nEach question counts "
    << exam.getPointsEach() << " points.\n";
    cout << "The minimum passing score is "
    << exam.getMinPassingScore() << endl;
    cout << "The student's exam score is "
    << exam.getScore() << endl;
    cout << "The student's grade is "
    << exam.getLetterGrade() << endl;
        return 0;
    }
```

## Program Output with Example Input Shown in Bold

How many questions are on the exam? 100 Enter
How many questions did the student miss? 25 Enter
Enter the minimum passing score for this test: $\mathbf{6 0}$ Enter
Each question counts 1.0 points.
The minimum passing score is 60.0
The student's exam score is 75.0
The student's grade is $P$
This program uses the PassFailExam object to call the getLetterGrade member function in line 37. Recall that the PassFailActivity class redefines the getLetterGrade function to report only grades of ' P ' or ' F '. Because the PassFai1Exam class is derived from the PassFailActivity class, it inherits the redefined getLetterGrade function.

Software designers often use class hierarchy diagrams. Like a family tree, a class hierarchy diagram shows the inheritance relationships between classes. Figure $15-5$ shows a class hierarchy for the GradedActivity, Fina1Exam, PassFailActivity, and PassFailExam classes. The more general classes are toward the top of the tree, and the more specialized classes are toward the bottom.

Figure 15-5 Class hierarchy

### 15.6 Polymorphism and Virtual Member Functions

CONCEPT: Polymorphism allows an object reference variable or an object pointer to reference objects of different types and to call the correct member functions, depending upon the type of object being referenced.

VideoNote
Polymorphism

Look at the following code for a function named displayGrade:

```
void displayGrade(const GradedActivity &activity)
{
    cout << setprecision(1) << fixed;
    cout << "The activity's numeric score is "
        << activity.getScore() << endl;
    cout << "The activity's letter grade is "
        << activity.getLetterGrade() << endl;
}
```

This function uses a const GradedActivity reference variable as its parameter. When a GradedActivity object is passed as an argument to this function, the function calls the object's getScore and getLetterGrade member functions to display the numeric score and letter grade. The following code shows how we might call the function:

```
GradedActivity test(88.0); // The score is 88
displayGrade(test); // Pass test to displayGrade
```

This code will produce the following output:

```
The activity's numeric score is 88.0
The activity's letter grade is B
```

Recall the GradedActivity class is also the base class for the Fina1Exam class. Because of the "is-a" relationship between a base class and a derived class, an object of the Fina1Exam class is not just a FinalExam object. It is also a GradedActivity object. (A final exam is a graded activity.) Because of this relationship, we can also pass a FinalExam object to the displayGrade function. For example, look at the following code:

```
// There are 100 questions. The student missed 25.
Fina1Exam test2(100, 25);
disp1ayGrade(test2);
```

This code will produce the following output:

```
The activity's numeric score is 75.0
The activity's letter grade is C
```

Because the parameter in the displayGrade function is a GradedActivity reference variable, it can reference any object that is derived from GradedActivity. A problem can occur with this type of code, however, when redefined member functions are involved. For example, recall that the PassFailActivity class is derived from the GradedActivity class. The PassFailActivity class redefines the getLetterGrade function. Although we can pass a PassFailActivity object as an argument to the displayGrade function, we will not get the results we wish. This is demonstrated in Program 15-10. (This file is available in the Student Source Code Folder Chapter 15\PassFailActivity.)

## Program 15-10

```
#include <iostream>
#include <iomanip>
#include "PassFailActivity.h"
using namespace std;
// Function prototype
void displayGrade(const GradedActivity &);
int main()
{
    // Create a PassFailActivity object. Minimum passing
    // score is 70.
    PassFailActivity test(70);
    // Set the score to 72.
    test.setScore(72);
    // Display the object's grade data. The letter grade
    // should be 'P'. What will be displayed?
    displayGrade(test);
    return 0;
}
//*****************************************************************
// The displayGrade function displays a GradedActivity object's *
// numeric score and letter grade.
||**********************************************************************
void displayGrade(const GradedActivity &activity)
{
    cout << setprecision(1) << fixed;
    cout << "The activity's numeric score is "
        << activity.getScore() << endl;
    cout << "The activity's letter grade is "
        << activity.getLetterGrade() << endl;
}
```

## Program Output

The activity's numeric score is 72.0
The activity's letter grade is C
As you can see from the example output, the getLetterGrade member function returned ' C ' instead of ' P '. This is because the GradedActivity class's getLetterGrade function was executed instead of the PassFailActivity class's version of the function.
This behavior happens because of the way C++ matches function calls with the correct function. This process is known as binding. In Program 15-10, C++ decides at compile time which version of the getLetterGrade function to execute when it encounters the call to the function in line 35 . Even though we passed a PassFailActivity object to the displayGrade function, the activity parameter in the displayGrade function is a

GradedActivity reference variable. Because it is of the GradedActivity type, the compiler binds the function call in line 35 with the GradedActivity class's getLetterGrade function. When the program executes, it has already been determined by the compiler that the GradedActivity class's getLetterGrade function will be called. The process of matching a function call with a function at compile time is called static binding.

To remedy this, the getLetterGrade function can be made virtual. A virtual function is a member function that is dynamically bound to function calls. In dynamic binding, C++ determines which function to call at runtime, depending on the type of the object responsible for the call. If a GradedActivity object is responsible for the call, C++ will execute the GradedActivity::getLetterGrade function. If a PassFailActivity object is responsible for the call, C++ will execute the PassFailActivity: :getLetterGrade function.

Virtual functions are declared by placing the key word virtual before the return type in the base class's function declaration, such as

```
virtual char getLetterGrade() const;
```

This declaration tells the compiler to expect getLetterGrade to be redefined in a derived class. The compiler does not bind calls to the function with the actual function. Instead, it allows the program to bind calls, at runtime, to the version of the function that belongs to the same class as the object responsible for the call.

NOTE: You place the virtual key word only in the function's declaration or prototype. If the function is defined outside the class, you do not place the virtual key word in the function header.

The following code shows an updated version of the GradedActivity class, with the getLetterGrade function declared virtua1. This file can be found in the Student Source Code Folder Chapter 15\GradedActivity Version 3. The GradedActivity.cpp file has not changed, so it is not shown again.

## Contents of GradedActivity.h (Version 3)

```
#ifndef GRADEDACTIVITY_H
#define GRADEDACTIVITY_H
// GradedActivity class declaration
class GradedActivity
{
protected:
    double score; // To hold the numeric score
public:
    // Default constructor
    GradedActivity()
            { score = 0.0; }
    // Constructor
    GradedActivity(doub1e s)
            { score = s; }
```

```
    // Mutator function
    void setScore(double s)
    { score = s; }
    // Accessor functions
    double getScore() const
        { return score; }
    virtual char getLetterGrade() const;
};
#endif
```

The only change we have made to this class is to declare getLetterGrade as virtual in line 27. This tells the compiler not to bind calls to getLetterGrade with the function at compile time. Instead, calls to the function will be bound dynamically to the function at runtime.

When a member function is declared virtual in a base class, any redefined versions of the function that appear in derived classes automatically become virtual. So, it is not necessary to declare the getLetterGrade function in the PassFailActivity class as virtual. It is still a good idea to declare the function virtual in the PassFailActivity class for documentation purposes. A new version of the PassFailActivity class is shown here. This file can be found in the Student Source Code Folder Chapter 15\GradedActivity Version 3. The PassFailActivity.cpp file has not changed, so it is not shown again.

## Contents of PassFailActivity.h

```
#ifndef PASSFAILACTIVITY_H
#define PASSFAILACTIVITY_H
#include "GradedActivity.h"
class PassFailActivity : public GradedActivity
{
protected:
    double minPassingScore; // Minimum passing score
    pub1ic:
        // Default constructor
        PassFailActivity() : GradedActivity()
            { minPassingScore = 0.0; }
        // Constructor
        PassFailActivity(doub1e mps) : GradedActivity()
            { minPassingScore = mps; }
        // Mutator
        void setMinPassingScore(double mps)
            { minPassingScore = mps; }
        // Accessors
        double getMinPassingScore() const
            { return minPassingScore; }
        virtual char getLetterGrade() const;
};
#endif
```

The only change we have made to this class is to declare getLetterGrade as virtual in line 26. Program 15-11 is identical to Program 15-10, except it uses the corrected version of the GradedActivity and PassFailActivity classes. This file is also available in the student source code folder Chapter 15\GradedActivity Version 3.

## Program 15-11

```
#include <iostream>
#include <iomanip>
#include "PassFailActivity.h"
using namespace std;
// Function prototype
void displayGrade(const GradedActivity &);
int main()
{
    // Create a PassFailActivity object. Minimum passing
    // score is 70.
    PassFailActivity test(70);
    // Set the score to 72.
    test.setScore(72);
    // Display the object's grade data. The letter grade
    // should be 'P'. What will be displayed?
    displayGrade(test);
    return 0;
}
//***************************************************************
// The displayGrade function displays a GradedActivity object's *
// numeric score and letter grade.
//*****************************************************************
void displayGrade(const GradedActivity &activity)
{
    cout << setprecision(1) << fixed;
    cout << "The activity's numeric score is "
        << activity.getScore() << endl;
    cout << "The activity's letter grade is "
        << activity.getLetterGrade() << endl;
}
```

## Program Output

The activity's numeric score is 72.0
The activity's letter grade is $P$

Now that the getLetterGrade function is declared virtual, the program works properly. This type of behavior is known as polymorphism. The term polymorphism means the ability to take many forms. Program 15-12 demonstrates polymorphism by passing objects of the GradedActivity and PassFailExam classes to the displayGrade function. This file can be found in the Student Source Code Folder Chapter 15\GradedActivity Version 3.

## Program 15-12

```
#include <iostream>
#include <iomanip>
#include "PassFailExam.h"
using namespace std;
// Function prototype
void displayGrade(const GradedActivity &);
int main()
{
    // Create a GradedActivity object. The score is 88.
    GradedActivity test1(88.0);
    // Create a PassFailExam object. There are 100 questions,
    // the student missed 25 of them, and the minimum passing
    // score is 70.
    PassFailExam test2(100, 25, 70.0);
    // Display the grade data for both objects.
    cout << "Test 1:\n";
    displayGrade(test1); // GradedActivity object
    cout << "\nTest 2:\n";
    displayGrade(test2); // PassFailExam object
    return 0;
}
|/|*************************************************************
// The displayGrade function displays a GradedActivity object's *
// numeric score and letter grade.
//*****************************************************************
void displayGrade(const GradedActivity &activity)
{
    cout << setprecision(1) << fixed;
    cout << "The activity's numeric score is "
            << activity.getScore() << endl;
    cout << "The activity's letter grade is "
        << activity.getLetterGrade() << endl;
}
```

## Program Output

Test 1:
The activity's numeric score is 88.0
The activity's letter grade is B

Test 2:
The activity's numeric score is 75.0
The activity's letter grade is $P$

## Polymorphism Requires References or Pointers

The displayGrade function in Programs 15-11 and 15-12 uses a GradedActivity reference variable as its parameter. When we call the function, we pass an object by reference. Polymorphic behavior is not possible when an object is passed by value, however. For example, suppose the displayGrade function had been written as shown here:

```
// Polymorphic behavior is not possible with this function.
void displayGrade(const GradedActivity activity)
{
    cout << setprecision(1) << fixed;
    cout << "The activity's numeric score is "
        << activity.getScore() << endl;
    cout << "The activity's letter grade is "
        << activity.getLetterGrade() << endl;
}
```

In this version of the function, the activity parameter is an object variable, not a reference variable. Suppose we call this version of the function with the following code:

```
// Create a GradedActivity object. The score is 88.
GradedActivity test1(88.0);
// Create a PassFailExam object. There are 100 questions,
// the student missed 25 of them, and the minimum passing
// score is 70.
PassFailExam test2(100, 25, 70.0);
// Display the grade data for both objects.
cout << "Test 1:\n";
displayGrade(test1); // Pass the GradedActivity object
cout << "\nTest 2:\n";
displayGrade(&test2); // Pass the PassFailExam object
```

This code will produce the following output:

```
Test 1:
The activity's numeric score is 88.0
The activity's letter grade is B
Test 2:
The activity's numeric score is 75.0
The activity's letter grade is C
```

Even though the getLetterGrade function is declared virtual, static binding still takes place because activity is not a reference variable or a pointer.

Alternatively, we could have used a GradedActivity pointer in the displayGrade function, as shown in Program 15-13. This file is also available in the Student Source Code Folder Chapter 15\GradedActivity Version 3.

## Program 15-13

```
#include <iostream>
#include <iomanip>
#include "PassFailExam.h"
using namespace std;
// Function prototype
void displayGrade(const GradedActivity *);
int main()
{
    // Create a GradedActivity object. The score is 88.
    GradedActivity test1(88.0);
    // Create a PassFailExam object. There are 100 questions,
    // the student missed 25 of them, and the minimum passing
    // score is 70.
    PassFailExam test2(100, 25, 70.0);
    // Display the grade data for both objects.
    cout << "Test 1:\n";
    displayGrade(&test1); // Address of the GradedActivity object
    cout << "\nTest 2:\n";
    displayGrade(&test2); // Address of the PassFailExam object
    return 0;
}
//**************************************************************
// The displayGrade function displays a GradedActivity object's *
// numeric score and letter grade. This version of the function *
// uses a GradedActivity pointer as its parameter.
//*****************************************************************
void displayGrade(const GradedActivity *activity)
{
    cout << setprecision(1) << fixed;
    cout << "The activity's numeric score is "
            << activity->getScore() << endl;
    cout << "The activity's letter grade is "
        << activity->getLetterGrade() << endl;
}
```

## Program Output

```
Test 1:
The activity's numeric score is 88.0
The activity's letter grade is B
Test 2:
The activity's numeric score is 75.0
The activity's letter grade is P
```

## Base Class Pointers

Pointers to a base class may be assigned the address of a derived class object. For example, look at the following code:

```
GradedActivity *exam = new PassFailExam(100, 25, 70.0);
```

This statement dynamically allocates a PassFailExam object and assigns its address to exam, which is a GradedActivity pointer. We can then use the exam pointer to call member functions, as shown here:

```
cout << exam->getScore() << endl;
cout << exam->getLetterGrade() << endl;
```

Program 15-14 is an example that uses base class pointers to reference derived class objects. This file can be found in the Student Source Code Folder Chapter 15\GradedActivity Version 3.

## Program 15-14

```
#include <iostream>
#include <iomanip>
#include "PassFailExam.h"
using namespace std;
// Function prototype
void displayGrade(const GradedActivity *);
int main()
{
    // Constant for the size of an array.
    const int NUM_TESTS = 4;
    // tests is an array of GradedActivity pointers.
    // Each element of tests is initialized with the
    // address of a dynamically allocated object.
    GradedActivity *tests[NUM_TESTS] =
        { new GradedActivity(88.0),
            new PassFailExam(100, 25, 70.0),
            new GradedActivity(67.0),
            new PassFai1Exam(50, 12, 60.0)
        };
```

## Program 15-14 (continued)

```
    // Display the grade data for each element in the array.
    for (int count = 0; count < NUM_TESTS; count++)
    {
        cout << "Test #" << (count + 1) << ":\n";
        displayGrade(tests[count]);
        cout << endl;
        }
        return 0;
}
//*****************************************************************
// The displayGrade function displays a GradedActivity object's *
// numeric score and letter grade. This version of the function *
// uses a GradedActivity pointer as its parameter.
//*****************************************************************
void displayGrade(const GradedActivity *activity)
{
    cout << setprecision(1) << fixed;
    cout << "The activity's numeric score is "
        << activity->getScore() << endl;
    cout << "The activity's letter grade is "
        << activity->getLetterGrade() << endl;
}
```

## Program Output

Test \#1:
The activity's numeric score is 88.0
The activity's letter grade is B

Test \#2:
The activity's numeric score is 75.0
The activity's letter grade is $P$

Test \#3:
The activity's numeric score is 67.0
The activity's letter grade is D

Test \#4:
The activity's numeric score is 76.0
The activity's letter grade is $P$

Let's take a closer look at this program. An array named tests is defined in lines 17 through 22. This is an array of GradedActivity pointers. The array elements are initialized with the addresses of dynamically allocated objects. The tests[0] element is initialized with the address of the GradedActivity object returned from this expression:

```
new GradedActivity(88.0)
```

The tests [1] element is initialized with the address of the GradedActivity object returned from this expression:

```
new PassFai1Exam(100, 25, 70.0)
```

The tests [2] element is initialized with the address of the GradedActivity object returned from this expression:

```
new GradedActivity(67.0)
```

Finally, the tests [3] element is initialized with the address of the GradedActivity object returned from this expression:

```
new PassFailExam(50, 12, 60.0)
```

Although each element in the array is a GradedActivity pointer, some of the elements point to GradedActivity objects, and some point to PassFailExam objects. The loop in lines 25 through 30 steps through the array, passing each pointer element to the displayGrade function.

## Base Class Pointers and References Know Only about Base Class Members

Although a base class pointer can reference objects of any class that derives from the base class, there are limits to what the pointer can do with those objects. Recall that the GradedActivity class has, other than its constructors, only three member functions: setScore, getScore, and getLetterGrade. So, a GradedActivity pointer can be used to call only those functions, regardless of the type of object to which it points. For example, look at the following code:

```
GradedActivity *exam = new PassFailExam(100, 25, 70.0);
cout << exam->getScore() << endl; // This works.
cout << exam->getLetterGrade() << endl; // This works.
cout << exam->getPointsEach() << endl; // ERROR! Won't work!
```

In this code, exam is a GradedActivity pointer, and is assigned the address of a PassFailExam object. The GradedActivity class has only the setScore, getScore, and getLetterGrade member functions, so those are the only member functions the exam variable knows how to execute. The last statement in this code is a call to the getPointsEach member function, which is defined in the PassFailExam class. Because the exam variable only knows about member functions in the GradedActivity class, it cannot execute this function.

## The "Is-a" Relationship Does Not Work in Reverse

It is important to note that the "is-a" relationship does not work in reverse. Although the statement "a final exam is a graded activity" is true, the statement "a graded activity is a
final exam" is not true. This is because not all graded activities are final exams. Likewise, not all GradedActivity objects are FinalExam objects. So, the following code will not work:

```
// Create a GradedActivity object.
GradedActivity *gaPointer = new GradedActivity(88.0);
// Error! This will not work.
FinalExam *fePointer = gaPointer;
```

You cannot assign the address of a GradedActivity object to a FinalExam pointer. This makes sense because FinalExam objects have capabilities that go beyond those of a GradedActivity object. Interestingly, the C++ compiler will let you make such an assignment if you use a type cast, as shown here:

```
// Create a GradedActivity object.
GradedActivity *gaPointer = new GradedActivity(88.0);
// This will work, but with limitations.
FinalExam *fePointer = static_cast<FinalExam *>(gaPointer);
```

After this code executes, the derived class pointer fePointer will be pointing to a base class object. We can use the pointer to access members of the object, but only the members that exist. The following code demonstrates:

```
// This will work. The object has a getScore function.
cout << fePointer->getScore() << endl;
// This will work. The object has a getLetterGrade function.
cout << fePointer->getLetterGrade() << endl;
// This will compile, but an error will occur at runtime.
// The object does not have a getPointsEach function.
cout << fePointer->getPointsEach() << endl;
```

In this code, fePointer is a FinalExam pointer, and it points to a GradedActivity object. The first two cout statements work because the GradedActivity object has getScore and a getLetterGrade member functions. The last cout statement will cause an error, however, because it calls the getPointsEach member function. The GradedActivity object does not have a getPointsEach member function.

## Redefining versus Overriding

Earlier in this chapter, you learned how a derived class can redefine a base class member function. When a class redefines a virtual function, it is said that the class overrides the function. In $\mathrm{C}++$, the difference between overriding and redefining base class functions is that overridden functions are dynamically bound, and redefined functions are statically bound. Only virtual functions can be overridden.

## Virtual Destructors

When you write a class with a destructor, and that class could potentially become a base class, you should always declare the destructor virtual. This is because the compiler will perform static binding on the destructor if it is not declared virtual. This can lead to problems when a base class pointer or reference variable references a derived class object. If the
derived class has its own destructor, it will not execute when the object is destroyed or goes out of scope. Only the base class destructor will execute. Program 15-15 demonstrates this.

## Program 15-15

```
#include <iostream>
using namespace std;
// Animal is a base class.
class Animal
{
public:
    // Constructor
    Anima1()
            { cout << "Animal constructor executing.\n"; }
    // Destructor
    ~Anima1()
    { cout << "Animal destructor executing.\n"; }
};
// The Dog class is derived from Animal
class Dog : public Animal
{
public:
    // Constructor
    Dog() : Animal()
        { cout << "Dog constructor executing.\n"; }
    // Destructor
    ~Dog()
        { cout << "Dog destructor executing.\n"; }
};
//************************************************
// main function
/|*************************************************
int main()
{
    // Create a Dog object, referenced by an
    // Animal pointer.
    Animal *myAnimal = new Dog;
    // Delete the dog object.
    delete myAnimal;
    return 0;
}
```

## Program Output

Animal constructor executing.
Dog constructor executing.
Animal destructor executing.

This program declares two classes: Animal and Dog. Animal is the base class and Dog is the derived class. Each class has its own constructor and destructor. In line 38, a Dog object is created, and its address is stored in an Animal pointer. Both the Animal and the Dog constructors execute. In line 41, the object is deleted. When this statement executes, however, only the Animal destructor executes. The Dog destructor does not execute because the object is referenced by an Animal pointer. We can fix this problem by declaring the Animal class destructor virtual, as shown in Program 15-16.

## Program 15-16

```
#include <iostream>
using namespace std;
// Animal is a base class.
class Animal
{
public:
        // Constructor
        Animal()
            { cout << "Animal constructor executing.\n"; }
        // Destructor
        virtual ~Animal()
            { cout << "Animal destructor executing.\n"; }
};
// The Dog class is derived from Animal
class Dog : public Animal
{
public:
    // Constructor
    Dog() : Animal()
            { cout << "Dog constructor executing.\n"; }
    // Destructor
        ~Dog()
            { cout << "Dog destructor executing.\n"; }
};
//***************************************************
// main function
//****************************************************
int main()
{
    // Create a Dog object, referenced by an
    // Animal pointer.
        Animal *myAnimal = new Dog;
    // Delete the dog object.
    delete myAnimal;
    return 0;
}
```

## Program Output

Animal constructor executing.
Dog constructor executing.
Dog destructor executing.
Animal destructor executing.

The only thing that has changed in this program is that the Animal class destructor is declared virtual in line 13 . As a result, the destructor is dynamically bound at runtime. When the Dog object is destroyed, both the Animal and Dog destructors execute.

A good programming practice to follow is that any class that has a virtual member function should also have a virtual destructor. If the class doesn't require a destructor, it should have a virtual destructor that performs no statements. Remember, when a base class function is declared virtual, all overridden versions of the function in derived classes automatically become virtual. Including a virtual destructor in a base class, even one that does nothing, will ensure that any derived class destructors will also be virtual.

## C++ 11's override and final Key Words

C++ 11 introduces the override key word to help prevent subtle errors when overriding virtual functions. For example, can you find the mistake in Program 15-17?

## Program 15-17

```
// This program has a subtle error in the virtual functions.
#include <iostream>
using namespace std;
class Base
{
public:
    virtual void functionA(int arg) const
            { cout << "This is Base::functionA" << endl; }
};
class Derived : public Base
{
public:
    virtual void functionA(long arg) const
        { cout << "This is Derived::functionA" << endl; }
};
int main()
{
    // Allocate instances of the Derived class.
    Base *b = new Derived();
    Derived *d = new Derived();
    // Call functionA with the two pointers.
    b->functionA(99);
```

## Program 15-17 (continued)

```
27 d->functionA(99);
28
29 return 0;
30 }
```

## Program Output

This is Base::functionA
This is Derived::functionA
Both the Base class and the Derived class have a virtual member function named functionA.
Notice in lines 22 and 23 in the main function, we allocate two instances of the Derived class. We reference one of the instances with a Base class pointer (b), and we reference the other instance with a Derived class pointer (d). When we call functionA in lines 26 and 27, we might expect that the Derived class's functionA would be called in both lines. This is not the case, however, as you can see from the program's output.

The functionA in the Derived class does not override the functionA in the Base class because the function signatures are different. The functionA in the Base class takes an int argument, but the one in the Derived class takes a long argument. So, functionA in the Derived class merely overloads functionA in the Base class.

To make sure a member function in a derived class overrides a virtual member function in a base class, you can use the override key word in the derived class's function prototype (or the function header, if the function is written inline). The override key word tells the compiler that the function is supposed to override a function in the base class. It will cause a compiler error if the function does not actually override any functions. Program 15-18 demonstrates how Program 15-17 can be fixed so the Derived class function does, in fact, override the Base class function. Notice in line 15 we have changed the parameter in the Derived class function to an int, and we have added the override key word to the function header.

## Program 15-18

```
// This program demonstrates the override key word.
#include <iostream>
using namespace std;
class Base
{
public:
    virtual void functionA(int arg) const
    { cout << "This is Base::functionA" << endl; }
};
class Derived : public Base
{
public:
```

```
    virtual void functionA(int arg) const override
    { cout << "This is Derived::functionA" << endl; }
};
int main()
{
    // Allocate instances of the Derived class.
    Base *b = new Derived();
    Derived *d = new Derived();
    // Call functionA with the two pointers.
    b->functionA(99);
    d->functionA(99);
    return 0;
}
```

## Program Output

This is Derived::functionA
This is Derived::functionA

## Preventing a Member Function from Being Overridden

In some derived classes, you might want to make sure a virtual member function cannot be overridden any further down the class hierarchy. When a member function is declared with the final key word, it cannot be overridden in a derived class. The following member function prototype is an example that uses the final key word:

```
virtual void message() const final;
```

If a derived class attempts to override a final member function, the compiler generates an error.

### 15.7 Abstract Base Classes and Pure Virtual Functions

CONCEPT: An abstract base class cannot be instantiated, but other classes are derived from it. A pure virtual function is a virtual member function of a base class that must be overridden. When a class contains a pure virtual function as a member, that class becomes an abstract base class.

Sometimes it is helpful to begin a class hierarchy with an abstract base class. An abstract base class is not instantiated itself, but serves as a base class for other classes. The abstract base class represents the generic, or abstract, form of all the classes that are derived from it.

For example, consider a factory that manufactures airplanes. The factory does not make a generic airplane, but makes three specific types of planes: two different models of propdriven planes, and one commuter jet model. The computer software that catalogs the planes might use an abstract base class called Airplane. That class has members representing the common characteristics of all airplanes. In addition, it has classes for each of the three specific airplane models the factory manufactures. These classes have members representing
the unique characteristics of each type of plane. The base class, Airplane, is never instantiated, but is used to derive the other classes.

A class becomes an abstract base class when one or more of its member functions is a pure virtual function. A pure virtual function is a virtual member function declared in a manner similar to the following:

```
virtual void showInfo() = 0;
```

The $=0$ notation indicates that showInfo is a pure virtual function. Pure virtual functions have no body, or definition, in the base class. They must be overridden in derived classes. Additionally, the presence of a pure virtual function in a class prevents a program from instantiating the class. The compiler will generate an error if you attempt to define an object of an abstract base class.
For example, look at the following abstract base class Student. It holds data common to all students, but does not hold all the data needed for students of specific majors.

## Contents of Student. h

```
// Specification file for the Student class
#ifndef STUDENT_H
#define STUDENT_H
#include <string>
using namespace std;
class Student
{
protected:
    string name; // Student name
    string idNumber; // Student ID
    int yearAdmitted; // Year student was admitted
public:
    // Defau7t constructor
    Student()
            { name = "";
            idNumber = "";
            yearAdmitted = 0; }
    // Constructor
    Student(string n, string id, int year)
        { set(n, id, year); }
    // The set function sets the attribute data.
    void set(string n, string id, int year)
        { name = n; // Assign the name
                idNumber = id; // Assign the ID number
                yearAdmitted = year; } // Assign the year admitted
    // Accessor functions
    const string getName() const
        { return name; }
    const string getIdNum() const
        { return idNumber; }
```

36
37
Pure virtual function
virtual int getRemainingHours() const $=0$;
\};
\#endif

The Student class contains members for storing a student's name, ID number, and year admitted. It also has constructors and a mutator function for setting values in the name, idNumber, and yearAdmitted members. Accessor functions are provided that return the values in the name, idNumber, and yearAdmitted members. A pure virtual function named getRemainingHours is also declared.

The pure virtual function must be overridden in classes derived from the Student class. It was made a pure virtual function because this class is intended to be the base for classes that represent students of specific majors. For example, a CsStudent class might hold the data for a computer science student, and a BiologyStudent class might hold the data for a biology student. Computer science students must take courses in different disciplines than those taken by biology students. It stands to reason that the CsStudent class will calculate the number of hours taken in a different manner than the BiologyStudent class.

Let's look at an example of the CsStudent class.

## Contents of CsStudent.h

```
// Specification file for the CsStudent class
#ifndef CSSTUDENT_H
#define CSSTUDENT_H
#include "Student.h"
// Constants for required hours
const int MATH_HOURS = 20; // Math hours
const int CS_HOURS = 40; // Computer science hours
const int GEN_ED_HOURS = 60; // General Ed hours
class CsStudent : public Student
{
private:
    int mathHours; // Hours of math taken
    int csHours; // Hours of Computer Science taken
    int genEdHours; // Hours of general education taken
public:
    // Default constructor
    CsStudent() : Student()
                { mathHours = 0;
                csHours = 0;
                genEdHours = 0; }
```

```
    // Constructor
    CsStudent(string n, string id, int year) :
        Student(n, id, year)
        { mathHours = 0;
            csHours = 0;
            genEdHours = 0; }
        // Mutator functions
        void setMathHours(int mh)
        { mathHours = mh; }
        void setCsHours(int csh)
        { csHours = csh; }
        void setGenEdHours(int geh)
        { genEdHours = geh; }
        // Overridden getRemainingHours function,
        // defined in CsStudent.cpp
        virtual int getRemainingHours() const;
};
#endif
```

This file declares the following const int member variables in lines 7 through 9: MATH HOURS, CS_HOURS, and GEN_ED_HOURS. These variables hold the required number of math, computer science, and general education hours for a computer science student. The CsStudent class, which derives from the Student class, declares the following member variables in lines 14 through 16: mathHours, csHours, and genEdHours. These variables hold the number of math, computer science, and general education hours taken by the student. Mutator functions are provided to store values in these variables. In addition, the class overrides the pure virtual getRemainingHours function in the CsStudent.cpp file.

## Contents of CsStudent. cpp

```
#include <iostream>
#include "CsStudent.h"
using namespace std;
//*****************************************************
// The CsStudent::getRemainingHours function returns *
// the number of hours remaining to be taken.
//********************************************************
int CsStudent::getRemainingHours() const
{
    int reqHours, // Total required hours
    remainingHours; // Remaining hours
        // Calculate the required hours.
        reqHours = MATH_HOURS + CS_HOURS + GEN_ED_HOURS;
        // Calculate the remaining hours.
        remainingHours = reqHours - (mathHours + csHours +
                genEdHours);
```

21
22 // Return the remaining hours.
23 return remainingHours;
24 \}
Program 15-19 provides a simple demonstration of the class.

## Program 15-19

```
// This program demonstrates the CsStudent class, which is
// derived from the abstract base class, Student.
#include <iostream>
#include "CsStudent.h"
using namespace std;
int main()
{
    // Create a CsStudent object for a student.
    CsStudent student("Jennifer Haynes", "167W98337", 2006);
    // Store values for Math, Computer Science, and Genera1
    // Ed hours.
    student.setMathHours(12); // Student has taken 12 Math hours
    student.setCsHours(20); // Student has taken 20 CS hours
    student.setGenEdHours(40); // Student has taken 40 Gen Ed hours
    // Display the number of remaining hours.
    cout << "The student " << student.getName()
        << " needs to take " << student.getRemainingHours()
        << " more hours to graduate.\n";
    return 0;
}
```

## Program Output

The student Jennifer Haynes needs to take 48 more hours to graduate.

Remember the following points about abstract base classes and pure virtual functions:

- When a class contains a pure virtual function, it is an abstract base class.
- Pure virtual functions are declared with the $=0$ notation.
- Abstract base classes cannot be instantiated.
- Pure virtual functions have no body, or definition, in the base class.
- A pure virtual function must be overridden at some point in a derived class in order for it to become nonabstract.

## Checkpoint

15.9 Explain the difference between overloading a function and redefining a function.
15.10 Explain the difference between static binding and dynamic binding.
15.11 Are virtual functions statically bound or dynamically bound?
15.12 What will the following program display?

```
#include <iostream.>
using namespace std;
class First
{
protected:
    int a;
public:
    First(int x = 1)
            { a = x; }
```

        int getVal()
            \{ return a; \}
    \};
class Second : public First
\{
private:
int b;
public:
Second (int $y=5)$
\{ b = y; \}
int getVal()
\{ return b; \}
\};
int main()
\{
First object1;
Second object2;
cout << object1.getVal() << endl;
cout << object2.getVal() << endl;
return 0;
\}
15.13 What will the following program display?

```
#include <iostream>
using namespace std;
class First
{
protected:
    int a;
public:
    First(int x = 1)
            { a = x; }
        void twist()
            { a *= 2; }
        int getVal()
            { twist(); return a; }
};
```

```
class Second : public First
{
private:
    int b;
public:
    Second(int y = 5)
            { b = y; }
        void twist()
            { b *= 10; }
};
int main()
{
    First object1;
        Second object2;
        cout << object1.getVal() << endl;
        cout << object2.getVal() << endl;
        return 0;
}
```

15.14 What will the following program display?

```
#include <iostream>
using namespace std;
class First
{
protected:
    int a;
public:
    First(int x = 1)
        { a = x; }
        virtual void twist()
            { a *= 2; }
        int getVal()
            { twist(); return a; }
};
class Second : public First
{
private:
    int b;
public:
        Second(int y = 5)
            { b = y; }
        virtual void twist()
            { b *= 10; }
};
int main()
{
        First object1;
        Second object2;
```

```
    cout << object1.getVal() << endl;
    cout << object2.getVal() << endl;
    return 0;
}
```

15.15 What will the following program display?

```
#include <iostream>
using namespace std;
class Base
{
protected:
    int baseVar;
public:
    Base(int val = 2)
                { baseVar = val; }
        int getVar()
            { return baseVar; }
};
class Derived : public Base
{
private:
    int derivedVar;
public:
    Derived(int val = 100)
            { derivedVar = val; }
    int getVar()
            { return derivedVar; }
};
int main()
{
    Base *optr = nullptr;
    Derived object;
    optr = &object;
    cout << optr->getVar() << endl;
    return 0;
}
```

### 15.8 Multiple Inheritance

CONCEPT: Multiple inheritance is when a derived class has two or more base classes.
Previously, we discussed how a class may be derived from a second class that is itself derived from a third class. The series of classes establishes a chain of inheritance. In such a scheme, you might be tempted to think of the lowest class in the chain as having multiple base classes. A base class, however, should be thought of as the class that another class is
directly derived from. Even though there may be several classes in a chain, each class (below the topmost class) only has one base class.

Another way of combining classes is through multiple inheritance. Multiple inheritance is when a class has two or more base classes. This is illustrated in Figure 15-6.

Figure 15-6 Multiple inheritance

In Figure $15-6$, class C is directly derived from classes A and B and inherits the members of both. Neither class A nor B, however, inherits members from the other. Their members are only passed down to class C. Let's look at an example of multiple inheritance. Consider the two classes declared here:

## Contents of Date. $h$

```
// Specification file for the Date class
#ifndef DATE_H
#define DATE_H
class Date
{
protected:
    int day;
    int month;
    int year;
public:
    // Default constructor
    Date(int d, int m, int y)
        { day = 1; month = 1; year = 1900; }
    // Constructor
    Date(int d, int m, int y)
        { day = d; month = m; year = y; }
    // Accessors
    int getDay() const
        { return day; }
    int getMonth() const
        { return month; }
    int getYear() const
        { return year; }
};
#endif
```

## Contents of Time.h

```
// Specification file for the Time class
#ifndef TIME_H
#define TIME_H
class Time
{
protected:
    int hour;
    int min;
    int sec;
public:
    // Default constructor
    Time()
            { hour = 0; min = 0; sec = 0; }
    // Constructor
    Time(int h, int m, int s)
        { hour = h; min = m; sec = s; }
    // Accessor functions
    int getHour() const
        { return hour; }
    int getMin() const
            { return min; }
    int getSec() const
        { return sec; }
};
#endif
```

These classes are designed to hold integers that represent the date and time. They both can be used as base classes for a third class we will call DateTime:

## Contents of DateTime.h

```
// Specification file for the DateTime class
#ifndef DATETIME_H
#define DATETIME_H
#include <string>
#include "Date.h"
#include "Time.h"
using namespace std;
class DateTime : public Date, public Time
{
public:
    // Default constructor
    DateTime();
    // Constructor
    DateTime(int, int, int, int, int, int);
```

17
18
19
// The showDateTime function displays the // date and the time. void showDateTime() const;
\};
\#endif
In line 9 , the first line in the DateTime declaration reads

```
class DateTime : public Date, public Time
```

Notice there are two base classes listed, separated by a comma. Each base class has its own access specification. The general format of the first line of a class declaration with multiple base classes is

```
class DerivedClassName : AccessSpecification BaseClassName,
    AccessSpecification BaseClassName [, ...]
```

The notation in the square brackets indicates that the list of base classes with their access specifications may be repeated. (It is possible to have several base classes.)

## Contents of DateTime.cpp

```
// Implementation file for the DateTime class
#include <iostream>
#include <string>
#include "DateTime.h"
using namespace std;
//************************************************
// Default constructor
// Note that this constructor does nothing other
// than call default base class constructors.
//************************************************
DateTime::DateTime() : Date(), Time()
{}
//***************************************************
// Constructor
// Note that this constructor does nothing other *
// than call base class constructors.
//*************************************************
DateTime::DateTime(int dy, int mon, int yr, int hr, int mt, int sc) :
    Date(dy, mon, yr), Time(hr, mt, sc)
{}
//**************************************************
// The showDateTime member function displays the *
// date and the time.
//*************************************************
void DateTime::showDateTime() const
{
    // Display the date in the form MM/DD/YYYY.
    cout << getMonth() << "/" << getDay() << "/" << getYear() << " ";
```

33 // Display the time in the form HH:MM:SS.
34 cout << getHour() << ":" << getMin() << ":" << getSec() << endl;
35 \}

The class has two constructors: a default constructor and a constructor that accepts arguments for each component of a date and time. Let's look at the function header for the default constructor, in line 12:

```
DateTime::DateTime() : Date(), Time()
```

After the DateTime constructor's parentheses is a colon, followed by calls to the Date constructor and the Time constructor. The calls are separated by a comma. When using multiple inheritance, the general format of a derived class's constructor header is

```
DerivedClassName(ParameterList) : BaseClassName(ArgumentList),
    BaseClassName(ArgumentList)[, ...]
```

Look at the function header for the second constructor, which appears in lines 20 and 21:

```
DateTime::DateTime(int dy, int mon, int yr, int hr, int mt, int sc) :
    Date(dy, mon, yr), Time(hr, mt, sc)
```

This DateTime constructor accepts arguments for the day (dy), month (mon), year (yr), hour (hr), minute (mt), and second (sc). The dy, mon, and yr parameters are passed as arguments to the Date constructor. The $\mathrm{hr}, \mathrm{mt}$, and sc parameters are passed as arguments to the Time constructor.

The order that the base class constructor calls appear in the list does not matter. They are always called in the order of inheritance. That is, they are always called in the order they are listed in the first line of the class declaration. Here is line 9 from the DateTime.h file:

```
class DateTime : public Date, public Time
```

Because Date is listed before Time in the DateTime class declaration, the Date constructor will always be called first. If the classes use destructors, they are always called in reverse order of inheritance. Program 15-20 shows these classes in use.

## Program 15-20

```
// This program demonstrates a class with multiple inheritance.
#include "DateTime.h"
using namespace std;
int main()
{
    // Define a DateTime object and use the default
    // constructor to initialize it.
    DateTime emptyDay;
    // Display the object's date and time.
    emptyDay.showDateTime();
    // Define a DateTime object and initialize it
    // with the date 2/4/1960 and the time 5:32:27.
```

```
    DateTime pastDay(2, 4, 1960, 5, 32, 27);
    // Display the object's date and time.
    pastDay.showDateTime();
    return 0
}
```

## Program Output

1/1/1900 0:0:0
4/2/1960 5:32:27

NOTE: It should be noted that multiple inheritance opens the opportunity for a derived class to have ambiguous members. That is, two base classes may have member variables or functions of the same name. In situations like these, the derived class should always redefine or override the member functions. Calls to the member functions of the appropriate base class can be performed within the derived class using the scope resolution operator (::). The derived class can also access the ambiguously named member variables of the correct base class using the scope resolution operator. If these steps aren't taken, the compiler will generate an error when it can't tell which member is being accessed.

## Checkpoint

15.16 Does the following diagram depict multiple inheritance or a chain of inheritance?

15.17 Does the following diagram depict multiple inheritance or a chain of inheritance?

15.18 Examine the following classes. The table lists the variables that are members of the Third class (some are inherited). Complete the table by filling in the access specification each member will have in the Third class. Write "inaccessible" if a member is inaccessible to the Third class.
class First
\{
private:

```
            int a;
    protected:
        double b;
    public:
        long c;
};
class Second : protected First
{
    private:
        int d;
    protected:
        double e;
    public:
        long f;
};
class Third : public Second
{
    private:
                int g;
        protected:
            double h;
        public:
        long i;
};
```

Member Variable
Access Specification in Third Class
a
b
c
d
e
f
g
h
i
15.19 Examine the following class declarations:

```
class Van
{
protected:
    int passengers;
public:
    Van(int p)
    { passengers = p; }
};
```

```
class FourByFour
{
protected:
    double cargoWeight;
public:
    FourByFour(float w)
        { cargoWeight = w; }
};
```

Write the declaration of a class named SportUtility. The class should be derived from both the Van and FourByFour classes above. (This should be a case of multiple inheritance, where both Van and FourByFour are base classes.)

## Review Questions and Exercises

## Short Answer

1. What is an "is a" relationship?
2. A program uses two classes: Dog and Poodle. Which class is the base class, and which is the derived class?
3. How does base class access specification differ from class member access specification?
4. What is the difference between a protected class member and a private class member?
5. Can a derived class ever directly access the private members of its base class?
6. Which constructor is called first, that of the derived class or the base class?
7. What is the difference between redefining a base class function and overriding a base class function?
8. When does static binding take place? When does dynamic binding take place?
9. What is a pure virtual function? When is it necessary?
10. A program has a class Potato, which is derived from the class Vegetable, which is derived from the class Food. Is this an example of multiple inheritance? Why or why not?
11. What are the base class(es) in the following line? What type of an inheritance is this? class Marks : public Exam, public Sports
12. What derived class is named in the line below?
class Pet : public Dog
13. What is the class access specification of the base class named below?
class Pet : public Dog
14. What is the class access specification of the base class named below?
```
class Pet : Fish
```

15. Protected members of a base class are like $\qquad$ members, except they may be accessed by derived classes.
16. Complete the table on the next page by filling in private, protected, public, or inaccessible in the right-hand column:
```
In a private base class, this base class ...becomes this access specification in
MEMBER access specification... the derived class.
```

```
private
protected
pub1ic
```

17. Complete the table below by filling in private, protected, public, or inaccessible in the right-hand column:

| In a protected base class, this base class | ...becomes this access specification in <br> the derived class. |
| :--- | :--- |
| MEMBER access specification... |  |

private
protected
public
18. Complete the table below by filling in private, protected, public, or inaccessible in the right-hand column:

In a public base class, this base class MEMBER access specification...
...becomes this access specification in the derived class.
private
protected
public

## Fill-in-the-Blank

19. A $\qquad$ or $\qquad$ class member can be accessed from derived class(es).
20. When both a base class and a derived class have constructors, the base class's constructor is called $\qquad$ (first/last).
21. When both a base class and a derived class have destructors, the base class's constructor is called $\qquad$ (first/last).
22. $\mathrm{A}(\mathrm{n})$ $\qquad$ access specifier allows a member to be accessible only from within the class and from a derived class.
23. When a derived class redefines a function in a base class, which version of the function do objects that are defined of the base class call? $\qquad$
24. $\mathrm{A}(\mathrm{n})$ $\qquad$ member function in a base class expects to be overridden in a derived class.
25. $\qquad$ binding is when the compiler binds member function calls at compile time.
26. Matching a function call with the correct function is called $\qquad$ .
27. $\qquad$ is when member functions in a class hierarchy behave differently, depending upon which object performs the call.
28. When a pointer to a base class is made to point to a derived class, the pointer ignores any $\qquad$ the derived class performs, unless the function is $\qquad$ .
29. $\mathrm{A}(\mathrm{n})$ $\qquad$ class cannot be instantiated.
30. A class can be made abstract by the inclusion of $a(n)$ $\qquad$ .
31. $\mathrm{A}(\mathrm{n})$ $\qquad$ of inheritance is where one class is derived from a second class, which in turn is derived from a third class.
32. The header for a pure virtual function myfunc () is $\qquad$ .
33. In multiple inheritance, the derived class should always $\qquad$ a function that has the same name in more than one base class.

## Algorithm Workbench

34. Write the first line of the declaration for a Pood1e class. The class should be derived from the Dog class with public base class access.
35. Write the first line of the declaration for aclass A. The class A should derive from three classes $B, C$, and $D$, where the base class access specification is different for each base class. Mention all assumptions in comments line.
36. Suppose a class named Tiger is derived from both the Fel is class and the Carnivore class. Here is the first line of the Tiger class declaration:
```
class Tiger : public Felis, public Carnivore
```

Here is the function header for the Tiger constructor:

```
Tiger(int \(x\), int \(y)\) : Carnivore(x), Felis(y)
```

Which base class constructor is called first, Carnivore or Felis?
37. Write the declaration for class $B$. The class's members should be as follows:

- m: an integer. This variable should not be accessible to code outside the class or to member functions in any class derived from class $B$.
- n : an integer. This variable should not be accessible to code outside the class, but should be accessible to member functions in any class derived from class $B$.
- setM, getM, setN, and getN: These are the set and get functions for the member variables $m$ and $n$. These functions should be accessible to code outside the class.
- calc: a public virtual member function that returns the value of $m$ times $n$.

Next, write the declaration for class $D$, which is derived from class $B$. The class's members should be as follows:

- q: a float. This variable should not be accessible to code outside the class but should be accessible to member functions in any class derived from class D.
- r: a float. This variable should not be accessible to code outside the class, but should be accessible to member functions in any class derived from class $D$.
- setQ, getQ, setR, and getR: These are the set and get functions for the member variables $q$ and $r$. These functions should be accessible to code outside the class.
- calc: a public member function that overrides the base class calc function. This function should return the value of $q$ times $r$.

## True or False

38. T F Inheritance represents an "IS-A" relation, unlike aggregation that represents a "HAS-A" relation among classes.
39. T F The base class's access specification affects the way the derived class inherits members of the base class.
40. T F Private members of a private base class become inaccessible to the derived class.
41. T F When a derived class is added to a base class, the base class needs to be amply changed according to the derived class specifications.
42. T F Protected members of a private base class become public members of the derived class.
43. T F Public members of a protected base class become private members of the derived class.
44. T F If the constructor is defined in the base class but not in the derived class, the compiler reports an error.
45. T F Protected members of a public base class become public members of the derived class.
46. T F The base class constructor is called after the derived class constructor.
47. T F The base class destructor is called after the derived class destructor.
48. T F A virtual function is dynamically bound to function calls.
49. T F If a virtual function is defined outside a class, the virtual keyword cannot be placed in the function header.
50. T F If class $Z$ has two base classes $X$ and $Y$, and another class $W$ attempts to derive from class $Z$, the compiler will report an error.
51. T F Pointers to a base class may be assigned the address of a derived class object.
52. T F A base class may not be derived from another class.

## Find the Errors

Each of the class declarations and/or member function definitions below has errors. Find as many as you can.
53. class Typist public: Employee
\{ public:
float type_speed;
float output_month; Typist();
~Typist();
\};
54. class Rectangle: Shape, public protected
\{
protected:
double length;
double breadth;
Rectangle();
~Rectangle();
\};
55. class SnowMobile : Vehicle
\{
protected:

```
            int horsePower;
            double weight;
        public:
            SnowMobile(int h, double w), Vehicle(h)
            { horsePower = h; }
            ~SnowMobile();
    };
56. class Table : public Furniture
    {
        protected:
            int numSeats;
        public:
            Table(int n) : Furniture(numSeats)
            { numSeats = n; }
            ~Table();
    };
57. class Tank : public Cylinder
    {
        private:
            int fuelType;
            double gallons;
        public:
            Tank();
            ~Tank();
            void setContents(double);
            void setContents(double);
    };
58. class Marks : public Exam, Sports
    {
        int extra_curriculum;
        public:
            Marks(int x, int s, int e):: Exam(x), Sports(s)
            {
                extra_curriculum = e;
            }
};
```

## Programming Challenges

1. Employee and ProductionWorker Classes

Design a class named Employee. The class should keep the following information:

- Employee name
- Employee number
- Hire date

Write one or more constructors, and the appropriate accessor and mutator functions, for the class.

Next, write a class named ProductionWorker that is derived from the Employee class. The ProductionWorker class should have member variables to hold the following information:

- Shift (an integer)
- Hourly pay rate (a double)

The workday is divided into two shifts: day and night. The shift variable will hold an integer value representing the shift that the employee works. The day shift is shift 1 , and the night shift is shift 2 . Write one or more constructors, and the appropriate accessor and mutator functions, for the class. Demonstrate the classes by writing a program that uses a ProductionWorker object.

## 2. ShiftSupervisor Class

In a particular factory, a shift supervisor is a salaried employee who supervises a shift. In addition to a salary, the shift supervisor earns a yearly bonus when his or her shift meets production goals. Design a ShiftSupervisor class that is derived from the Employee class you created in Programming Challenge 1 (Employee and Production Worker Classes). The ShiftSupervisor class should have a member variable that holds the annual salary, and a member variable that holds the annual production bonus that a shift supervisor has earned. Write one or more constructors and the appropriate accessor and mutator functions for the class. Demonstrate the class by writing a program that uses a ShiftSupervisor object.

## 3. TeamLeader Class

In a particular factory, a team leader is an hourly paid production worker who leads a small team. In addition to hourly pay, team leaders earn a fixed monthly bonus. Team leaders are required to attend a minimum number of hours of training per year. Design a TeamLeader class that extends the ProductionWorker class you designed in Programming Challenge 1 (Employee and Production Worker Classes). The TeamLeader class should have member variables for the monthly bonus amount, the required number of training hours, and the number of training hours that the team leader has attended. Write one or more constructors and the appropriate accessor and mutator functions for the class. Demonstrate the class by writing a program that uses a TeamLeader object.

## 4. Time Format

In Program 15-20, the file Time.h contains a Time class. Design a class called MilTime that is derived from the Time class. The Mi1Time class should convert time in military (24-hour) format to the standard time format used by the Time class. The class should have the following member variables:
milHours: Contains the hour in 24-hour format. For example, 1:00 p.m. would be stored as 1300 hours, and 4:30 p.m. would be stored as 1630 hours.
mi1Seconds: Contains the seconds in standard format.
The class should have the following member functions:
Constructor: The constructor should accept arguments for the hour and seconds, in military format. The time should then be converted to standard time and stored in the hours, min, and sec variables of the Time class.
setTime: Accepts arguments to be stored in the milHours and milSeconds variables. The time should then be converted to standard time and stored in the hours, min, and sec variables of the Time class.
getHour: Returns the hour in military format.
getStandHr: Returns the hour in standard format.
Demonstrate the class in a program that asks the user to enter the time in military format. The program should then display the time in both military and standard format.
Input Validation: The Mi1Time class should not accept hours greater than 2359, or less than 0 . It should not accept seconds greater than 59 or less than 0.

## 5. Time Clock

Design a class named TimeClock. The class should be derived from the MilTime class you designed in Programming Challenge 4 (Time Format). The class should allow the programmer to pass two times to it: starting time and ending time. The class should have a member function that returns the amount of time elapsed between the two times. For example, if the starting time is 900 hours (9:00 a.m.), and the ending time is 1300 hours ( $1: 00 \mathrm{p} . \mathrm{m}$.), the elapsed time is 4 hours.
Input Validation: The class should not accept hours greater than 2359 or less than 0.

## 6. Publishing Company

Design a class Publication, which has the following member variables: title, number_of_pages, year, and price. Derive the following two classes from this class:

- Book class adds a member variable author.
- Magazine class adds member variables month and yearly_subscription_price.

Include appropriate constructors, and set and get functions for all the classes. Demonstrate the classes in a complete program.

## 7. Positions in Coordinate System

Design a Position class that represents the position of a point in a two-dimensional space. The class should have the following member variables:

- x_coord that represents the position along the $x$-axis
- y_coord that represents the position along the $y$-axis

Include appropriate accessor and mutator functions in it.
Next, design a class named Restricted_Position that restricts the position of a point to an area in the first quadrant. Note that in the first quadrant, the values of x _coord and y -coord are always positive. The class should have the following member variables:

- maximum_x that represents the maximum position along the $x$-axis
- maximum_y that represents the maximum position along the $y$-axis

The mutator function of the Position class should be revised so that the position of a point is within the limits set by maximum_x and maximum_y.
Now design a class named Restricted_3D_Position that represents a point in a bounded three-dimensional space. The class should have the following member variables:

- z_coord that represents the position along the $z$-axis
- maximum $\_z$ that represents the maximum position along the $z$-axis

Include appropriate accessor and mutator functions in it. Demonstrate an object of Restricted_3D_Position class in a simple program.

## 8. PreferredCustomer Class

A retail store has a preferred customer plan where customers may earn discounts on all their purchases. The amount of a customer's discount is determined by the amount of the customer's cumulative purchases in the store.

- When a preferred customer spends $\$ 500$, he or she gets a 5 percent discount on all future purchases.
- When a preferred customer spends $\$ 1,000$, he or she gets a 6 percent discount on all future purchases.
- When a preferred customer spends $\$ 1,500$, he or she gets a 7 percent discount on all future purchases.
- When a preferred customer spends $\$ 2,000$ or more, he or she gets a 10 percent discount on all future purchases.
Design a class named PreferredCustomer, which is derived from the CustomerData class you created in Programming Challenge 7. The PreferredCustomer class should have the following member variables:
- purchasesAmount (a double)
- discountLevel (a double)

The purchasesAmount variable holds the total of a customer's purchases to date. The discountLeve 1 variable should be set to the correct discount percentage, according to the store's preferred customer plan. Write appropriate member functions for this class and demonstrate it in a simple program.

Input Validation: Do not accept negative values for any sales figures.

## 9. File Filter

A file filter reads an input file, transforms it in some way, and writes the results to an output file. Write an abstract file filter class that defines a pure virtual function for transforming a character. Create one derived class of your file filter class that performs encryption, another that transforms a file to all uppercase, and another that creates an unchanged copy of the original file. The class should have the following member function:

```
void doFilter(ifstream &in, ofstream &out)
```

This function should be called to perform the actual filtering. The member function for transforming a single character should have the prototype:

```
char transform(char ch)
```

The encryption class should have a constructor that takes an integer as an argument and uses it as the encryption key.

## 10. File Double-Spacer

Create a derived class of the abstract filter class of Programming Challenge 9 (File Filter) that double-spaces a file, that is, it inserts a blank line between any two lines of the file.

## 11. Backpack

Backpacks exist in various sizes, forms, and qualities. This may make it difficult to decide which backpack best suits your needs. Therefore, most manufacturers typically publish the following information about the backpack:

- The acceptable volume (in gallons)
- The acceptable weight (in pounds)

Both measurements are important: either things don't fit or the backpack will rip apart because the contents are too heavy.
Therefore, define an Item class that has the following members:

- Member variables for the description (string), volume and weight of that item.
- A constructor and appropriate accessors and mutators.
- A virtual print function that displays information about the item.

Then design a Backpack class that has the following members:

- Member variables for the acceptable volume and weight.
- Member variables for the actual volume and weight of the items in the backpack.
- A member variable for the list of items in the backpack.
- A constructor and appropriate accessors and mutators.
- Functions to add and remove items from the backpack. When adding an item, this is allowed only when the acceptable volume and weight are not exceeded.
- A virtual print function that displays all the information about the backpack.

Demonstrate the classes in a program.

## 12. Ship, CruiseShip, and CargoShip Classes

Design a Ship class that has the following members:

- A member variable for the name of the ship (a string)
- A member variable for the year that the ship was built (a string)
- A constructor and appropriate accessors and mutators
- A virtual print function that displays the ship's name and the year it was built.

Design a CruiseShip class that is derived from the Ship class. The CruiseShip class should have the following members:

- A member variable for the maximum number of passengers (an int)
- A constructor and appropriate accessors and mutators
- A print function that overrides the print function in the base class. The CruiseShip class's print function should display only the ship's name and the maximum number of passengers.
Design a CargoShip class that is derived from the Ship class. The CargoShip class should have the following members:
- A member variable for the cargo capacity in tonnage (an int)
- A constructor and appropriate accessors and mutators
- A print function that overrides the print function in the base class. The CargoShip class's print function should display only the ship's name and the ship's cargo capacity.

Demonstrate the classes in a program that has an array of Ship pointers. The array elements should be initialized with the addresses of dynamically allocated Ship, CruiseShip, and CargoShip objects. (See Program 15-14, lines 17 through 22, for an example of how to do this.) The program should then step through the array, calling each object's print function.

## 13. Art Works in a Museum

A museum keeps a record of all its exhibited artworks. An art object may be a painting, a sculpture, or a statue.
Design an abstract class ArtWork that should have the following member variables:

- total_number: This should be a static variable that keeps count of the total number of artworks that are recorded.
- serial: A serial number that should be automatically generated when an object of a derived class is created.
- artist: This stores the name of the artist.
- year: This stores the year in which the art object was created.

The class ArtWork should have the following member functions:

- A constructor that increments the member variable total_number and assigns the serial number to the current value of total_number.
- A mutator function.
- An accessor function.

Derive a Painting class from the ArtWork class. It should have the following members:

- type: This should denote the type of painting (like oil, watercolor, etc.).
- drawn_on: This should store the material on which the painting is drawn (like canvas, paper, wood, etc.).
Derive a Sculpture class from the ArtWork class. It should have the following members:
- height: This should store the height of the glass box required.
- size: This should store the length of the glass box. The length and breadth of the boxes are always the same.
- material: This should store the material with which the sculpture is made (like stone, wood, wax, etc.).
Derive a Statue class from the ArtWork class. It should have the following members:
- diameter: This should store the diameter of the pedestal required.

## Group Project

## 14. Crowdfunding

This program should be designed and written by a team of students. Here are some suggestions:

- Depending on the size of your team, each student may work on a single class, or you can divide the team into 3: one team works on the Person, ProjectOwner, and Investment classes, another team on the Project class, and a third team on the Crowdfunding class.
- The intended goal, parameters, and return types of each function and class member function should be decided in advance.
- The program will be best implemented as a multi-file program.

The concept of this group project is to implement a Crowdfunding platform. A project can subscribe on this platform to request a certain amount of funding from the public. Small investors can choose to put some of their money in the project and in return get early access to the results. The following classes are needed:

- A Person class that holds basic information about a person.
- A ProjectOwner class that is derived from the Person class and that additionally contains the Social Security number of the person and the nationality.
- An Investment class that keeps track of who invested how much at what date.
- A Project class that maintains information about the project, the project owner, and its investors.
- A CrowdfundingPlatform class that keeps track of all the projects and people on its platform.

The Person class is a very basic class consisting mainly of a person's name and a unique identifying number. Use a static member variable that keeps track of the number of people recorded and that creates unique numbers for the Person instances. The class should have the appropriate constructor, accessors, and mutators.
The ProjectOwner class derives from the Person class. It should have the following additional member variables and appropriate accessor functions for these variables:

- Social Security number (to be sure that the project owner really exists; because of the various representations of a Social Security number in different countries, this should be a string)
- Nationality (a string)

The Investment class has the following members:

- A reference to the investor (an instance of the Person class)
- The amount that the investor invests
- The date of the investment (a timestamp or any representation you choose)
- Appropriate constructor and accessor functions (mutator functions are not needed because the investment cannot be altered nor withdrawn)

The Project class should have the following members:

- Variable members for the name of the project, the amount of funding it would like to collect, the project owner, and a list of all investments
- A constructor that accepts as arguments the name of the project, the amount of funding, and the project owner
- The typical accessor and mutator functions
- A function member that returns the amount of funding that must still be collected
- A function member that returns a Boolean that indicates whether the funding is finalized
- A function member to add investments as long as the funding is not finalized

Finally, the CrowdfundingPl at form class should have the following variable members:

- A list of all projects within the platform
- A list of all people registered in the platform

Besides the typical constructor, accessor, and mutator functions, implement functions that

- can add a project to the platform
- can add a person to the platform
- can add an investment of a person for a project. This function should accept as arguments:
- A Person object
- A Project object
- The amount that is invested in that project

Write a complete program that demonstrates these classes.

16.4 Class Templates

### 16.1 Exceptions

CONCEPT: Exceptions are used to signal errors or unexpected events that occur while a program is running.

Error testing is usually a straightforward process involving if statements or other control mechanisms. For example, the following code segment will trap a division-by-zero error before it occurs:

```
if (denominator == 0)
    cout << "ERROR: Cannot divide by zero.\n";
else
    quotient = numerator / denominator;
```

But what if similar code is part of a function that returns the quotient, as in the following example?

```
// An unreliable division function
double divide(int numerator, int denominator)
{
    if (denominator == 0)
    {
        cout << "ERROR: Cannot divide by zero.\n";
        return 0;
    }
        else
            return static_cast<double>(numerator) / denominator;
}
```

VideoNote
Throwing an Exception

VideoNote
Handling an Exception

Functions commonly signal error conditions by returning a predetermined value. Apparently, the function in this example returns 0 when division by zero has been attempted. This is unreliable, however, because 0 is a valid result of a division operation. Even though the function displays an error message, the part of the program that calls the function will not know when an error has occurred. Problems like these require sophisticated error handling techniques.

## Throwing an Exception

One way of handling complex error conditions is with exceptions. An exception is a value or an object that signals an error. When the error occurs, an exception is "thrown." For example, the following code shows the divide function, modified to throw an exception when division by zero has been attempted:

```
double divide(int numerator, int denominator)
{
    if (denominator == 0)
        throw "ERROR: Cannot divide by zero.\n";
    else
    return static_cast<double>(numerator) / denominator;
}
```

The following statement causes the exception to be thrown:

```
throw "ERROR: Cannot divide by zero.\n";
```

The throw key word is followed by an argument, which can be any value. As you will see, the value of the argument is used to determine the nature of the error. The function above simply throws a string containing an error message.

The line containing a throw statement is known as the throw point. When a throw statement is executed, control is passed to another part of the program known as an exception handler. When an exception is thrown by a function, the function aborts.

## Handling an Exception

To handle an exception, a program must have a try/catch construct. The general format of the try/catch construct is:

```
try
{
    // code here calls functions or object member
    // functions that might throw an exception.
}
catch(ExceptionParameter)
{
    // code here handles the exception
}
// Repeat as many catch blocks as needed.
```

The first part of the construct is the try block. This starts with the key word try and is followed by a block of code executing any statements that might directly or indirectly cause an exception to be thrown. The try block is immediately followed by one or more catch blocks,
which are the exception handlers. A catch block starts with the key word catch, followed by a set of parentheses containing the definition of an exception parameter. For example, here is a try/catch construct that can be used with the divide function:

```
try
{
    quotient = divide(num1, num2);
    cout << "The quotient is " << quotient << endl;
}
catch (string exceptionString)
{
    cout << exceptionString;
}
```

Because the divide function throws an exception whose value is a string, there must be an exception handler that catches a string. The catch block shown catches the error message in the exceptionString parameter then displays it with cout. Now let's look at an entire program to see how throw, try, and catch work together. In the first sample run of Program 16-1, valid data are given. This shows how the program should run with no errors. In the second sample running, a denominator of 0 is given. This shows the result of the exception being thrown.

## Program 16-1

// This program demonstrates an exception being thrown and caught.
\#include <iostream>
\#include <string>
using namespace std;
// Function prototype
double divide(int, int);
int main()
\{
int num1, num2; // To hold two numbers
double quotient; // To hold the quotient of the numbers
// Get two numbers.
cout << "Enter two numbers: ";
cin >> num1 >> num2;
// Divide num1 by num2 and catch any
// potential exceptions.
try
\{
quotient = divide(num1, num2);
cout << "The quotient is " << quotient << endl;
\}
catch (string exceptionString)
\{
cout << exceptionString;
\}

```
Program 16-1 (continued)
```

```
    cout << "End of the program.\n";
```

    cout << "End of the program.\n";
        return 0;
        return 0;
    }
    }
    //**********************************************
    //**********************************************
    // The divide function divides the numerator *
    // The divide function divides the numerator *
    // by the denominator. If the denominator is *
    // by the denominator. If the denominator is *
    // zero, the function throws an exception.
    // zero, the function throws an exception.
    /l***********************************************
/l***********************************************
double divide(int numerator, int denominator)
double divide(int numerator, int denominator)
{
{
if (denominator == 0)
if (denominator == 0)
{
{
string exceptionString = "ERROR: Cannot divide by zero.\n";
string exceptionString = "ERROR: Cannot divide by zero.\n";
throw exceptionString;
throw exceptionString;
}
}
return static_cast<double>(numerator) / denominator;
return static_cast<double>(numerator) / denominator;
}

```
}
```

## Program Output with Example Input Shown in Bold

Enter two numbers: 122 Enter
The quotient is 6
End of the program.

## Program Output with Different Example Input Shown in Bold

Enter two numbers: 120 Enter
ERROR: Cannot divide by zero.
End of the program.

As you can see from the second output screen, the exception caused the program to jump out of the divide function and into the catch block. After the catch block has finished, the program resumes with the first statement after the try/catch construct. This is illustrated in Figure 16-1.

Figure 16-1 How the try/catch construct works

In the first output screen, the user entered nonnegative values. No exception was thrown in the try block, so the program skipped the catch block and jumped to the statement immediately following the try/catch construct, which is in line 30. This is illustrated in Figure 16-2.

Figure 16-2 No exception was thrown
If no exception is thrown in the try block, the program jumps to the statement that immediately follows the try/catch construct.

```
```

```
try
```

```
try
{
{
    quotient = divide(num1, num2);
    quotient = divide(num1, num2);
    cout << "The quotient is " << quotient << endl;
    cout << "The quotient is " << quotient << endl;
```

}

```
}
catch (string exceptionString)
catch (string exceptionString)
{
{
    cout << exceptionString;
    cout << exceptionString;
}
}
cout << "End of the program.\n";
cout << "End of the program.\n";
return 0;
```

return 0;

```

\section*{What if an Exception Is Not Caught?}

There are two possible ways for a thrown exception to go uncaught. The first possibility is for the try/catch construct to contain no catch blocks with an exception parameter of the right data type. The second possibility is for the exception to be thrown from outside a try block. In either case, the exception will cause the entire program to abort execution.

\section*{Object-Oriented Exception Handling with Classes}

Now that you have an idea of how the exception mechanism in C++ works, we will examine an object-oriented approach to exception handling. Recall the Rectangle class that was introduced in Chapter 13. That class had the mutator functions setWidth and setLength for setting the rectangle's width and length. If a negative value was passed to either of these functions, the class displayed an error message and aborted the program. The following code shows an improved version of the Rectangle class. This version throws an exception when a negative value is passed to setWidth or setLength. (These files can be found in the Student Source Code Folder Chapter 16\Rectangle Version 1.)

\section*{Contents of Rectangle.h (Version 1)}
```

// Specification file for the Rectangle class
\#ifndef RECTANGLE_H
\#define RECTANGLE_H
class Rectangle
{
private:
double width; /l The rectangle's width
double length; // The rectangle's length
pub1ic:
// Exception class
class NegativeSize
{ }; // Empty class declaration

```
                13
                14
```

15 // Default constructor
1 6 ~ R e c t a n g 1 e ( )
1 7
18
19
20
21
22
23 // Accessor functions
24 doub1e getWidth() const
25 { return width; }
26
27
28
29
30 double getArea() const
31 { return width * length; }
32 };
33 \#endif

```

Notice the empty class declaration that appears in the public section, in lines 12 and 13. The NegativeSize class has no members. The only important part of the class is its name, which will be used in the exception-handling code. Now look at the Rectangle.cpp file, where the setWidth and setLength member functions are defined.

\section*{Contents of Rectang1e.cpp (Version 1)}
```

// Implementation file for the Rectangle class.
\#include "Rectangle.h"
//*********************************************************
// setWidth sets the value of the member variable width.
//**********************************************************
void Rectangle::setWidth(double w)
{
if (w >= 0)
width = w;
else
throw NegativeSize();
}
/|*************************************************************
// setLength sets the value of the member variable length.
|/**************************************************************
void Rectangle::setLength(double len)
{
if (len >= 0)
length = 1en;
else
throw NegativeSize();
}

```

In the setWidth function, the parameter \(w\) is tested by the if statement in line 10 . If \(w\) is greater than or equal to 0 , its value is assigned to the width member variable. If \(w\) holds a negative number, however, the statement in line 13 is executed.
```

throw NegativeSize();

```

The throw statement's argument, NegativeSize(), causes an instance of the NegativeSize class to be created and thrown as an exception.

The same series of events takes place in the setLength function. If the value in the len parameter is greater than or equal to 0 , its value is assigned to the length member variable. If 1 en holds a negative number, an instance of the NegativeSize class is thrown as an exception in line 25.

This way of reporting errors is much more graceful than simply aborting the program. Any code that uses the Rectangle class must simply have a catch block to handle the NegativeSize exceptions that the Rectangle class might throw. Program 16-2 shows an example. (This file can be found in the Student Source Code Folder Chapter 16\Rectangle Version 1.)

\section*{Program 16-2}
// This program demonstrates Rectangle class exceptions.
\#include <iostream>
\#include "Rectangle.h"
using namespace std;
int main()
\{
    double width;
    double length;
    // Create a Rectangle object.
    Rectangle myRectangle;
    // Get the width and length.
    cout << "Enter the rectangle's width: ";
    cin >> width;
    cout << "Enter the rectangle's length: ";
    cin >> length;
    // Store these values in the Rectangle object.
    try
    \{
            myRectangle.setWidth(width);
            myRectangle.setLength(length);
            cout << "The area of the rectangle is "
                    << myRectangle.getArea() << endl;
    \}
    catch (Rectangle:: NegativeSize)
    \{
        cout << "Error: A negative value was entered. 1 n ";
    \}
(program continues)
```

Program 16-2 (continued)
32 cout << "End of the program.\n";
33
34 return 0;
35 }

```
Program Output with Example Input Shown in Bold
Enter the rectangle's width: 10 Enter
Enter the rectangle's length: 20 Enter
The area of the rectangle is 200
End of the program.

\section*{Program Output with Different Example Input Shown in Bold}
```

Enter the rectangle's width: 5 Enter
Enter the rectangle's length: -5 Enter
Error: A negative value was entered.
End of the program.

```

The catch statement in line 28 catches the NegativeSize exception when it is thrown by any of the statements in the try block. Inside the catch statement's parentheses is the name of the NegativeSize class. Because the NegativeSize class is declared inside the Rectangle class, we have to fully qualify the class name with the scope resolution operator.

Notice we did not define a parameter of the NegativeSize class in the catch statement. In this case, the catch statement only needs to specify the type of exception it handles.

\section*{Multiple Exceptions}

The programs we have studied so far test only for a single type of error and throw only a single type of exception. In many cases, a program will need to test for several different types of errors and signal which one has occurred. C++ allows you to throw and catch multiple exceptions. The only requirement is that each different exception be of a different type. You then code a separate catch block for each type of exception that may be thrown in the try block.
For example, suppose we wish to expand the Rectangle class so it throws one type of exception when a negative value is specified for the width, and another type of exception when a negative value is specified for the length. First, we declare two different exception classes, such as:
```

// Exception class for a negative width
class NegativeWidth
{ };
// Exception class for a negative length
class NegativeLength
{ };

```

An instance of NegativeWidth will be thrown when a negative value is specified for the width, and an instance of NegativeLength will be thrown when a negative value is specified for the length. The code for the modified Rectangle class is shown here. (These files can be found in the Student Source Code Folder Chapter 16\Rectangle Version 2.)

\section*{Contents of Rectang1e.h (Version 2)}
```

// Specification file for the Rectangle class
\#ifndef RECTANGLE_H
\#define RECTANGLE_H
class Rectang1e
{
private:
double width; // The rectangle's width
double length; // The rectangle's length
public:
// Exception class for a negative width
class NegativeWidth
{ };
// Exception class for a negative length
class NegativeLength
{ };
// Default constructor
Rectangle()
{ width = 0.0; length = 0.0; }
// Mutator functions, defined in Rectangle.cpp
void setWidth(double);
void setLength(double);
// Accessor functions
double getWidth() const
{ return width; }
double getLength() const
{ return length; }
double getArea() const
{ return width * length; }
};
\#endif

```

\section*{Contents of Rectangle.cpp (Version 2)}
```

// Implementation file for the Rectangle class.
\#include "Rectangle.h"
//*************************************************************
// setWidth sets the value of the member variable width
//************************************************************
void Rectangle::setWidth(double w)
{
if (w >= 0)
width = w;

```
```

        else
        throw NegativeWidth();
        }
        l/************************************************************
        // setLength sets the value of the member variable length.
        / /*
        void Rectang1e::setLength(doub1e 1en)
        {
        if (len >= 0)
            1ength = 1en;
        else
            throw NegativeLength();
        }
    ```

Notice in the definition of the setWidth function (in Rectangle.cpp) that an instance of the NegativeWidth class is thrown in line 13. In the definition of the setLength function, an instance of the NegativeLength class is thrown in line 25. Program 16-3 demonstrates this class. (This file can be found in the Student Source Code Folder Chapter 161 Rectangle Version 2.)

\section*{Program 16-3}
// This program demonstrates Rectangle class exceptions.
\#include <iostream>
\#include "Rectangle.h"
using namespace std;
int main()
\{
double width;
double length;
// Create a Rectangle object.
Rectangle myRectangle;
// Get the width and length.
cout << "Enter the rectangle's width: ";
cin >> width;
cout << "Enter the rectangle's length: ";
cin >> length;
// Store these values in the Rectangle object.
try
\{
myRectangle.setWidth(width) ;
myRectangle.setLength(1ength);
cout << "The area of the rectangle is "
<< myRectangle.getArea() << endl;
\}
catch (Rectangle:: NegativeWidth)
```

29
30
31
32
33
34
35
36
37
38
39
4 0
41 }

```
```

Program Output with Example Input Shown in Bold
Enter the rectangle's width: 10 Enter
Enter the rectangle's length: 20 Enter
The area of the rectangle is 200
End of the program.

```
Program Output with Different Example Input Shown in Bold
Enter the rectangle's width: -5 Enter
Enter the rectangle's length: 5 Enter
Error: A negative value was given for the rectangle's width.
End of the program.
Program Output with Different Example Input Shown in Bold
Enter the rectangle's width: 5 Enter
Enter the rectangle's length: - \(\mathbf{5}\) Enter
Error: A negative value was given for the rectangle's length.
End of the program.

The try block, in lines 21 through 27, contains code that can throw two different types of exceptions. The statement in line 23 can potentially throw a NegativeWidth exception, and the statement in line 24 can potentially throw a NegativeLength exception. To handle each of these types of exception, there are two catch statements. The statement in line 28 catches NegativeWidth exceptions, and the statement in line 33 catches Negat iveLength exceptions.
When an exception is thrown by code in the try block, C++ searches the try/catch construct for a catch statement that can handle the exception. If the construct contains a catch statement that is compatible with the exception, control of the program is passed to the catch block.

\section*{Using Exception Handlers to Recover from Errors}

Program 16-3 demonstrates how a try/catch construct can have several catch statements in order to handle different types of exceptions. However, the program does not use the exception handlers to recover from any of the errors. When the user enters a negative value for either the width or the length, this program still halts. Program 16-4 shows a better example of effective exception handling. It attempts to recover from the exceptions and get valid data from the user. (This file can be found in the Student Source Code Folder Chapter 16\Rectangle Version 2.)

\section*{Program 16-4}
```

// This program handles the Rectangle class exceptions.
\#include <iostream>
\#include "Rectangle.h"
using namespace std;
int main()
{
double width; // Rectangle's width
double length; // Rectangle's length
bool tryAgain = true; // Flag to reread input
// Create a Rectangle object.
Rectangle myRectangle;
// Get the rectangle's width.
cout << "Enter the rectangle's width: ";
cin >> width;
// Store the width in the myRectangle object.
while (tryAgain)
{
try
{
myRectangle.setWidth(width);
// If no exception was thrown, then the
// next statement will execute.
tryAgain = false;
}
catch (Rectangle::NegativeWidth)
{
cout << "Please enter a nonnegative value: ";
cin >> width;
}
}
// Get the rectangle's length.
cout << "Enter the rectangle's length: ";
cin >> length;
// Store the length in the myRectangle object.
tryAgain = true;
while (tryAgain)
{
try
{
myRectangle.setLength(length);
// If no exception was thrown, then the
// next statement will execute.
tryAgain = false;
}
catch (Rectangle::NegativeLength)

```
```

52
53
54
55
56
57
58
5 9
6 0
6 1
return 0;
}

```

\section*{Program Output with Example Input Shown in Bold}

Enter the rectangle's width: -1 Enter
Please enter a nonnegative value: 10 Enter
Enter the rectangle's length: -5 Enter
Please enter a nonnegative value: 50 Enter
The rectangle's area is 500

Let's look at how this program recovers from a NegativeWidth exception. In line 10, a bool flag variable, tryAgain, is defined and initialized with the value true. This variable will indicate whether we need to get a value from the user again. Lines 16 and 17 prompt the user to enter the rectangle's width. Then, the program enters the while loop in lines 20 through 34. The loop repeats as long as tryAgain is true. Inside the loop, the Rectang1e class's setWidth member function is called in line 24 . This statement is in a try block. If a NegativeWidth exception is thrown, the program will jump to the catch statement in line 29. In the catch block that follows, the user is asked to enter a nonnegative number. The program then jumps out of the try/catch construct. Because tryAgain is still true, the loop will repeat.

If a nonnegative number is passed to the setWidth member function in line 24 , no exception will be thrown. In that case, the statement in line 27 will execute, which sets tryAgain to false. The program then jumps out of the try/catch construct. Because tryAgain is now false, the loop will not repeat.

The same strategy is used in lines 37 through 56 to get and validate the rectangle's length.

\section*{Extracting Data from the Exception Class}

Sometimes we might want an exception object to pass data back to the exception handler. For example, suppose we would like the Rectangle class not only to signal when a negative value has been given, but also to pass the value back. This can be accomplished by giving the exception class members in which data can be stored.

In our next modification of the Rectangle class, the NegativeWidth and NegativeLength classes have been expanded, each with a member variable and a constructor. Here is the code for the NegativeWidth class:
```

class NegativeWidth
{
private:
double value;

```
```

public:
NegativeWidth(double val)
{ value = val; }
double getValue() const
{ return value; }
};

```

When we throw this exception, we want to pass the invalid value as an argument to the class's constructor. This is done in the setWidth member function with the following statement:
```

throw NegativeWidth(w);

```

This throw statement creates an instance of the Negat iveWidth class and passes a copy of the w variable to the constructor. The constructor then stores this number in NegativeWidth's member variable, value. The class instance carries this member variable to the catch block that intercepts the exception.

In the catch block, the value is extracted with code such as
```

catch (Rectangle::NegativeWidth e)
{
cout << "Error: " << e.getValue()
<< " is an invalid value for the"
<< " rectangle's width.\n";
}

```

Notice the catch block defines a parameter object named e. This is necessary because we want to call the class's getValue function to retrieve the value that caused the exception.

Here is the code for the NegativeLength class:
```

class NegativeLength
{
private:
double value;
public:
NegativeLength(double val)
{ value = val; }
double getValue() const
{ return value; }
};

```

This class also has a member variable named value, and a constructor that initializes the variable. When we throw this exception, we follow the same general steps that were just described for the NegativeWidth exception. The complete code for the revised Rectangle class is shown here. Program 16-5 demonstrates these classes. (These files can be found in the Student Source Code Folder Chapter 16\Rectangle Version 3.)

\section*{Contents of Rectang1e.h (Version 3)}

int main()
{
double width;
double length;
// Create a Rectangle object.
Rectangle myRectangle;
// Get the width and length.
cout << "Enter the rectangle's width: ";
cin >> width;
cout << "Enter the rectangle's length: ";
cin >> length;
// Store these values in the Rectangle object.
try

```
```

    {
        myRectang1e.setWidth(width);
        myRectangle.setLength(length);
        cout << "The area of the rectangle is "
        << myRectangle.getArea() << endl;
    }
    catch (Rectang1e::NegativeWidth e)
    {
        cout << "Error: " << e.getValue()
        << " is an invalid value for the"
        << " rectangle's width.\n";
    }
    catch (Rectangle::NegativeLength e)
    {
        cout << "Error: " << e.getValue()
        << " is an invalid value for the"
        << " rectangle's length.\n";
    }
    cout << "End of the program.\n";
    return 0;
}

```

\section*{Program Output with Example Input Shown in Bold}
```

Enter the rectangle's width: -1 Enter
Enter the rectangle's length: 10 Enter
Error: -1 is an invalid value for the rectangle's width.
End of the program.

```

\section*{Program Output with Different Example Input Shown in Bold}

Enter the rectangle's width: 5 Enter
Enter the rectangle's length: -1 Enter
Error: -1 is an invalid value for the rectangle's length.
End of the program.

\section*{Unwinding the Stack}

Once an exception has been thrown, the program cannot jump back to the throw point. The function that executes a throw statement will immediately terminate. If that function was called by another function, and the exception is not caught, then the calling function will terminate as well. This process, known as unwinding the stack, continues for the entire chain of nested function calls, from the throw point, all the way back to the try block.

If an exception is thrown by the member function of a class object, then the class destructor is called. If statements in the try block (or statements branching from the try block) created any other objects, their destructors will be called as well.

\section*{Rethrowing an Exception}

It is possible for try blocks to be nested. For example, look at this code segment:
```

try
{
doSomething();
}
catch(exception1)
{
// code to handle exception 1
}
catch(exception2)
{
// code to handle exception 2
}

```

In this try block, the function doSomething is called. There are two catch blocks, one that handles exception1, and another that handles exception2. If the doSomething function also has a try block, then it is nested inside the one shown.

With nested try blocks, it is sometimes necessary for an inner exception handler to pass an exception to an outer exception handler. Sometimes both an inner and an outer catch block must perform operations when a particular exception is thrown. These situations require that the inner catch block rethrow the exception so the outer catch block has a chance to catch it.
A catch block can rethrow an exception with the throw statement. For example, suppose the doSomething function (called in the throw block above) calls the doSomethingE1se function, which potentially can throw exception1 or exception3. Suppose doSomething does not want to handle exception1. Instead, it wants to rethrow it to the outer block. The following code segment illustrates how this is done:
```

try
{
doSomethingElse();
}
catch(exception1)
{
throw; // Rethrow the exception
}
catch(exception3)
{
// Code to handle exception 3
}

```

When the first catch block catches exception1, the throw statement simply throws the exception again. The catch block in the outer try/catch construct will then handle the exception.

\section*{Handling the bad_a11oc Exception}

Recall from Chapter 9 that when the new operator fails to allocate memory, an exception is thrown. Now that you've seen how to handle exceptions, you can write code that determines whether the new operator was successful.

When the new operator fails to allocate memory, C++ throws a bad_alloc exception. The bad_alloc exception type is defined in the <new> header file, so any program that attempts to catch this exception should have the following directive:
```

\#include <new>

```

The bad_alloc exception is in the std namespace, so be sure to have the using namespace std; statement in your code as well.

Here is the general format of a try/catch construct that catches the bad_alloc exception:
```

try
{
// Code that uses the new operator
}
catch (bad_alloc)
{
// Code that responds to the error
}

```

Program 16-6 shows an example. The program uses the new operator to allocate a \(10,000-\) element array of doubles. If the new operator fails, an error message is displayed.

\section*{Program 16-6}
```

// This program demonstrates the bad_alloc exception.
\#include <iostream>
\#include <new> // Needed for bad_alloc
using namespace std;
int main()
{
double *ptr = nullptr; // Pointer to double
try
{
ptr = new double [10000];
}
catch (bad_alloc)
{
cout << "Insufficient memory.\n";
}
return 0;
}

```

\section*{Checkpoint}
16.1 What is the difference between a try block and a catch block?
16.2 What happens if an exception is thrown, but not caught?
16.3 If multiple exceptions can be thrown, how does the catch block know which exception to catch?
16.4 After the catch block has handled the exception, where does program execution resume?
16.5 How can an exception pass data back to the exception handler?

\subsection*{16.2 Function Templates}

CONCEPT: A function template is a "generic" function that can work with any data type. The programmer writes the specifications of the function, but substitutes parameters for data types. When the compiler encounters a call to the function, it generates code to handle the specific data type(s) used in the call.

\section*{Introduction}

Overloaded functions make programming convenient because only one function name must be remembered for a set of functions that perform similar operations. Each of the functions, however, must still be written individually, even if they perform the same operation. For example, suppose a program uses the following overloaded square functions:
```

int square(int number)
{
return number * number;
}
double square(double number)
{
return number * number;
}

```

The only differences between these two functions are the data types of their return values and their parameters. In situations like this, it is more convenient to write a function template than an overloaded function. Function templates allow you to write a single function definition that works with many different data types, instead of having to write a separate function for each data type used.

A function template is not an actual function, but a "mold" the compiler uses to generate one or more functions. When writing a function template, you do not have to specify actual types for the parameters, return value, or local variables. Instead, you use a type parameter to specify a generic data type. When the compiler encounters a call to the function, it examines the data types of its arguments and generates the function code that will work with those data types. (The generated code is known as a template function.)

Here is a function template for the square function:
```

template <class T>
T square(T number)
{
return number * number;
}

```

The beginning of a function template is marked by a template prefix, which begins with the key word template. Next is a set of angled brackets that contains one or more generic data types used in the template. A generic data type starts with the key word class followed by a parameter name that stands for the data type. The example just given only uses one, which is named T . (If there were more, they would be separated by commas.) After this, the function definition is written as usual, except the type parameters are substituted for the actual data type names. In the example, the function header reads
```

T square(T number)

```

T is the type parameter, or generic data type. The header defines square as a function that returns a value of type \(T\) and uses a parameter, number, which is also of type \(T\). As mentioned before, the compiler examines each call to square and fills in the appropriate data type for \(T\). For example, the following call uses an int argument:
```

int y, x = 4;
y = square(x);

```

This code will cause the compiler to generate the function
```

int square(int number)
{
return number * number;
}

```
while the following statements
```

double y, f = 6.2
y = square(f);

```
will generate the function
```

doub1e square(doub1e number)
{
return number * number;
}

```

Program 16-7 demonstrates how this function template is used.

\section*{Program 16-7}
// This program uses a function template.
\#include <iostream>
\#include <iomanip>
using namespace std;
// Template definition for square function.
template <class T>
T square( T number)
\{
    return number * number;
\}
int main()
\{
    int userInt; // To hold integer input
    double userDouble; // To hold double input
    cout << setprecision(5);
    cout << "Enter an integer and a floating-point value: ";
    cin >> userInt >> userDouble;
    cout << "Here are their squares: ";
    cout \(\ll\) square(userInt) << " and "
        << square (userDouble) << endl;
        return 0;
\}
```

Program 16-7
(continued)
Program Output with Example Input Shown in Bold
Enter an integer and a floating-point value: 12 4.2 Enter
Here are their squares: 144 and 17.64

```

NOTE: All type parameters defined in a function template must appear at least once in the function parameter list.

Because the compiler encountered two calls to square in Program 16-7, each with a different parameter type, it generated the code for two instances of the function: one with an int parameter and int return type, the other with a double parameter and double return type. This is illustrated in Figure 16-3.

\section*{Figure 16-3 Generation of template functions}

Notice in Program 16-7 that the template appears before all calls to square. As with regular functions, the compiler must already know the template's contents when it encounters a call to the template function. Templates, therefore, should be placed near the top of the program or in a header file.

NOTE: A function template is merely the specification of a function and by itself does not cause memory to be used. An actual instance of the function is created in memory when the compiler encounters a call to the template function.

Program 16-8 shows another example of a function template. The function, swapVars, uses two references to type T as parameters. The function swaps the contents of the variables referenced by the parameters.

\section*{Program 16-8}
```

// This program demonstrates the swapVars function template.
\#include <iostream>
using namespace std;

```
4
```

template <class T>
void swapVars(T \&var1, T \&var2)
{
T temp;
temp = var1;
var1 = var2;
var2 = temp;
}
int main()
{
char firstChar, secondChar; // Two chars
int firstInt, secondInt; /l Two ints
double firstDouble, secondDouble; // Two doubles
// Get and swapVars two chars
cout << "Enter two characters: ";
cin >> firstChar >> secondChar;
swapVars(firstChar, secondChar);
cout << firstChar << " " << secondChar << endl;
// Get and swapVars two ints
cout << "Enter two integers: ";
cin >> firstInt >> secondInt;
swapVars(firstInt, secondInt);
cout << firstInt << " " << secondInt << endl;
// Get and swapVars two doubles
cout << "Enter two floating-point numbers: ";
cin >> firstDouble >> secondDouble;
swapVars(firstDouble, secondDouble);
cout << firstDouble << " " << secondDouble << endl;
return 0;
}

```

\section*{Program Output with Example Input Shown in Bold}

Enter two characters: ABEn Enter
B A
Enter two integers: 510 Enter
105
Enter two floating-point numbers: 1.2 9.6 Enter
9.61 .2

\section*{Using Operators in Function Templates}

The square template shown earlier uses the * operator with the number parameter. This works well as long as number is of a primitive data type such as int, float, and so on. If a user-defined class object is passed to the square function, however, the class must contain code for an overloaded * operator. If not, the compiler will generate a function with an error.

Always remember a class object passed to a function template must support all the operations the function will perform on the object. For instance, if the function performs a comparison on the object (with \(>,<,==\), or another relational operator), those operators must be overloaded by the class object.

\section*{Function Templates with Multiple Types}

More than one generic type may be used in a function template. Each type must have its own parameter, as shown in Program 16-9. This program uses a function template named larger. This template uses two type parameters: T1 and T2. The sizes of the function parameters, var1 and var2, are compared, and the function returns the number of bytes occupied by the larger of the two. Because the function parameters are specified with different types, the function generated from this template can accept two arguments of different types.

\section*{Program 16-9}
```

// This program demonstrates a function template
// with two type parameters.
\#include <iostream>
using namespace std;
template <class T1, class T2>
int largest(const T1 \&var1, T2 \&var2)
{
if (sizeof(var1) > sizeof(var2))
return sizeof(var1);
else
return sizeof(var2);
}
int main()
{
int i = 0;
char c = ' ';
float f = 0.0;
double d = 0.0;
cout << "Comparing an int and a double, the largest\n"
<< "of the two is " << largest(i, d) << " bytes.\n";
cout << "Comparing a char and a float, the largest\n"
<< "of the two is " << largest(c, f) << " bytes.\n";
return 0;
}

```

\section*{Program Output}

Comparing an int and a double, the largest of the two is 8 bytes.
Comparing a char and a float, the largest
of the two is 4 bytes.

NOTE: Each type parameter declared in the template prefix must be used somewhere in the template definition.

\section*{Overloading with Function Templates}

Function templates may be overloaded. As with regular functions, function templates are overloaded by having different parameter lists. For example, there are two overloaded versions of the sum function in Program 16-10. The first version accepts two arguments, and the second version accepts three.

\section*{Program 16-10}
```

// This program demonstrates an overloaded function template.
\#include <iostream>
using namespace std;
template <class T>
T sum(T val1, T val2)
{
return val1 + val2;
}
template <class T>
T sum(T va11, T val2, T val3)
{
return val1 + val2 + va13;
}
int main()
{
doub1e num1, num2, num3;
// Get two values and display their sum.
cout << "Enter two values: ";
cin >> num1 >> num2;
cout << "Their sum is " << sum(num1, num2) << end1;
// Get three values and display their sum.
cout << "Enter three values: ";
cin >> num1 >> num2 >> num3;
cout << "Their sum is " << sum(num1, num2, num3) << end1;
return 0;
}

```

\section*{Program Output with Example Input Shown in Bold}

Enter two values: 12.5 6.9 Enter
Their sum is 19.4
Enter three values: 45.7698 .3210 .51 Enter
Their sum is 154.59
There are other ways to perform overloading with function templates as well. For example, a program might contain a regular (nontemplate) version of a function as well as a template version. As long as each has a different parameter list, they can coexist as overloaded functions.

\subsection*{16.3 Focus on Software Engineering: Where to Start When Defining Templates}

Quite often, it is easier to convert an existing function into a template than to write a template from scratch. With this in mind, you should start designing a function template by writing it first as a regular function. For example, the swapVars template in Program 16-8 would have been started as something like the following:
```

void swapVars(int \&var1, int \&var2)
{
int temp;
temp = var1;
var1 = var2;
var2 = temp;
}

```

Once this function is properly tested and debugged, converting it to a template is a simple process. First, the template <class \(T>\) header is added, then all the references to int that must be changed are replaced with the data type parameter \(T\).

\section*{(1)}

\section*{Checkpoint}
16.6 When does the compiler actually generate code for a function template?
16.7 The following function accepts an int argument and returns half of its value as a double:
```

double half(int number)
{
return number / 2.0;
}

```

Write a template that will implement this function to accept an argument of any type.
16.8 What must you be sure of when passing a class object to a function template that uses an operator, such as * or >?
16.9 What is the best method for writing a function template?

\subsection*{16.4 Class Templates}

CONCEPT: Templates may also be used to create generic classes and abstract data types. Class templates allow you to create one general version of a class without having to duplicate code to handle multiple data types.

Recall the IntArray class from Chapter 14. By overloading the [] operator, this class allows you to implement int arrays that perform bounds checking. But suppose you would like to have a version of this class for other data types. Of course, you could design specialized classes such as LongArray, FloatArray, DoubleArray, and so forth. A better solution, however, is to design a single class template that works with any primitive data type. In this section, we will convert the IntArray class into a generalized template named SimpleVector.

Declaring a class template is very similar to declaring a function template. First, a template prefix, such as template <class \(T>\), is placed before the class declaration. As with function templates, T (or whatever identifier you choose to use) is a data type parameter. Then, throughout the class declaration, the data type parameter is used where you wish to support any data type. Below is the SimpleVector class template declaration.

\section*{Contents of SimpleVector.h}
```

// SimpleVector class template
\#ifndef SIMPLEVECTOR_H
\#define SIMPLEVECTOR_H
\#include <iostream>
\#include <new> // Needed for bad_alloc exception
\#include <cstdlib> // Needed for the exit function
using namespace std;
template <class T>
class SimpleVector
{
private:
T *aptr; // To point to the allocated array
int arraySize; /l Number of elements in the array
void memError(); // Handles memory allocation errors
void subError(); // Handles subscripts out of range
public:
// Default constructor
SimpleVector()
{ aptr = 0; arraySize = 0;}
// Constructor declaration
SimpleVector(int);
// Copy constructor declaration
SimpleVector(const SimpleVector \&);
// Destructor declaration
~SimpleVector();
// Accessor to return the array size
int size() const
{ return arraySize; }
// Accessor to return a specific element
T getElementAt(int position);
// Overloaded [] operator declaration
T \&operator[](const int \&);
};
/l**************************************************************
// Constructor for SimpleVector class. Sets the size of the *
// array and allocates memory for it.
//*****************************************************************

```
```

4 7
48 template <class T>
49 SimpleVector<T>::SimpleVector(int s)
50 {
51
52
53
5 4
55
5 6
5 7
5 8
59

arraySize = s;
// Allocate memory for the array.
try
{
aptr = new T [s];
}
catch (bad_a11oc)
{
memError();
}
// Initialize the array.
for (int count = 0; count < arraySize; count++)
*(aptr + count) = 0;
}
1/**
// Copy Constructor for SimpleVector class.
/|***********************************************
template <class T>
SimpleVector<T>::SimpleVector(const SimpleVector \&obj)
{
// Copy the array size.
arraySize = obj.arraySize;
// Allocate memory for the array.
aptr = new T [arraySize];
if (aptr == 0)
memError();
// Copy the elements of obj's array.
for(int count = 0; count < arraySize; count++)
*(aptr + count) = *(obj.aptr + count);
}
//***************************************
// Destructor for SimpleVector class. *
//***************************************
template <class T>
SimpleVector<T>::~SimpleVector()
{
if (arraySize > 0)
delete [] aptr;
}
//***********************************************************
// memError function. Displays an error message and
// terminates the program when memory allocation fails.
//***********************************************************

```

102
103
104 105 106 107 108 109
```

template <class T>
void SimpleVector<T>::memError()
{
cout << "ERROR:Cannot allocate memory.\n";
exit(EXIT_FAILURE);
}
//**************************************************************
// subError function. Displays an error message and
// terminates the program when a subscript is out of range.
||****************************************************************
template <class T>
void SimpleVector<T>::subError()
{
cout << "ERROR: Subscript out of range.\n";
exit(EXIT_FAILURE);
}
//********************************************************
// getElementAt function. The argument is a subscript.
// This function returns the value stored at the *
// subcript in the array.
//************************************************************
template <class T>
T SimpleVector<T>::getElementAt(int sub)
{
if (sub < 0 || sub >= arraySize)
subError();
return aptr[sub];
}
|/*********************************************************
// Overloaded [] operator. The argument is a subscript. *
// This function returns a reference to the element *
// in the array indexed by the subscript. *
//**********************************************************
template <class T>
T \&SimpleVector<T>::operator[](const int \&sub)
{
if (sub < 0 || sub >= arraySize)
subError();
return aptr[sub];
}

```

NOTE: The arraySize member variable is declared as an int. This is because it holds the size of the array, which will be an integer value, regardless of the data type of the array. This is also why the size member function returns an int.

\section*{Defining Objects of the Class Template}

Class template objects are defined like objects of ordinary classes, with one small difference: the data type you wish to pass to the type parameter must be specified. Placing the data type name inside angled brackets immediately following the class name does this. For example, the following statements create two SimpleVector objects: intTable and doubleTable.
```

SimpleVector<int> intTable(10);
SimpleVector<double> doubleTable(10);

```

In the definition of intTable, the data type int will be used in the template everywhere the type parameter T appears. This will cause intTable to store an array of ints. Likewise, the definition of doubleTable passes the data type double into the parameter \(T\), causing it to store an array of doubles. This is demonstrated in Program 16-11.

\section*{Program 16-11}
```

// This program demonstrates the SimpleVector template.
\#include <iostream>
\#include "SimpleVector.h"
using namespace std;
int main()
{
const int SIZE = 10; // Number of elements
int count; // Loop counter
// Create a SimpleVector of ints.
SimpleVector<int> intTable(SIZE);
// Create a SimpleVector of doubles.
SimpleVector<double> doubleTable(SIZE);
// Store values in the two SimpleVectors.
for (count = 0; count < SIZE; count++)
{
intTable[count] = (count * 2);
doubleTable[count] = (count * 2.14);
}
// Display the values in the SimpleVectors.
cout << "These values are in intTable:\n";
for (count = 0; count < SIZE; count++)
cout << intTable[count] << " ";
cout << endl;
cout << "These values are in doubleTable:\n";
for (count = 0; count < SIZE; count++)
cout << doubleTab1e[count] << " ";
cout << endl;
// Use the standard + operator on the elements.
cout << "\nAdding 5 to each element of intTable"
<< " and doubleTable.\n";
for (count = 0; count < SIZE; count++)

```

## Program Output

These values are in intTable:
024681012141618
These values are in doubleTable:
$\begin{array}{lllllllllll}0 & 2.14 & 4.28 & 6.42 & 8.56 & 10.7 & 12.84 & 14.98 & 17.12 & 19.26\end{array}$
Adding 5 to each element of intTable and doubleTable.
These values are in intTable:
$\begin{array}{llllllllll}5 & 7 & 9 & 11 & 13 & 15 & 17 & 19 & 21 & 23\end{array}$
These values are in doubleTable:
$\begin{array}{lllllllllllllllllllll}5 & 7.14 & 9.28 & 11.42 & 13.56 & 15.7 & 17.84 & 19.98 & 22.12 & 24.26\end{array}$
Incrementing each element of intTable and doubleTable.
These values are in intTable:
681012141618202224
These values are in doubleTable:
$\begin{array}{lllllllllllllllllll}6 & 8.14 & 10.28 & 12.42 & 14.56 & 16.7 & 18.84 & 20.98 & 23.12 & 25.26\end{array}$

## Class Templates and Inheritance

Inheritance can easily be applied to class templates. For example, in the following template, SearchableVector is derived from the SimpleVector class.

## Contents of SearchableVector.h

```
#ifndef SEARCHABLEVECTOR_H
#define SEARCHABLEVECTOR_H
#include "SimpleVector.h"
template <class T>
class SearchableVector : public SimpleVector<T>
{
pub1ic:
    // Default constructor
    SearchableVector() : SimpleVector<T>()
        { }
        // Constructor
        SearchableVector(int size) : SimpleVector<T>(size)
            { }
        // Copy constructor
        SearchableVector(const SearchableVector &);
        // Accessor to find an item
        int findItem(const T);
};
//*********************************************************
// Copy constructor
//*********************************************************
template <class T>
Searchab1eVector<T>: :SearchableVector(const SearchableVector &obj) :
                    SimpleVector<T>(obj.size())
{
    for(int count = 0; count < this->size(); count++)
        this->operator[](count) = obj[count];
}
//**********************************************************
// findItem function
// This function searches for item. If item is found
// the subscript is returned. Otherwise -1 is returned.
//********************************************************
template <class T>
int SearchableVector<T>::findItem(const T item)
{
    for (int count = 0; count <= this->size(); count++)
```

```
4 6
47
4 8
4 9
}
51 }
52 #endif
```

This class template defines a searchable version of the SimpleVector class. The member function findItem accepts an argument and performs a simple linear search to determine whether the argument's value is stored in the array. If the value is found in the array, its subscript is returned. Otherwise, -1 is returned.

Notice each time the name SimpleVector is used in the class template, the type parameter T is used with it. For example, here is the first line of the class declaration, in line 6, which names SimpleVector as the base class:

```
class SearchableVector : public SimpleVector<T>
```

Also, here are the function headers for the class constructors:

```
SearchableVector() : SimpleVector<T>()
SearchableVector(int size) : SimpleVector<T>(size)
```

Because SimpleVector is a class template, the type parameter must be passed to it.
Program 16-12 demonstrates the class by storing values in two SearchableVector objects, then searching for a specific value in each.

## Program 16-12

```
// This program demonstrates the SearchableVector template.
#include <iostream>
#include "SearchableVector.h"
using namespace std;
int main()
{
    const int SIZE = 10; // Number of elements
    int count; // Loop counter
    int result; // To hold search results
    // Create two SearchableVector objects.
    SearchableVector<int> intTable(SIZE);
    SearchableVector<double> doubleTable(SIZE);
    // Store values in the objects.
    for (count = 0; count < SIZE; count++)
    {
        intTable[count] = (count * 2);
        doubleTable[count] = (count * 2.14);
    }
```

## Program 16-12 (continued)

22

23
24
25
26
27
28
29
30
31
// Display the values in the objects.
cout << "These values are in intTable:\n";
for (count $=0$; count $<$ SIZE; count++)
cout << intTable[count] << " ";
cout << endl << endl;
cout << "These values are in doubleTable:\n";
for (count $=0$; count $<$ SIZE; count++)
cout << doubleTable[count] << " ";
cout << end1;
// Search for the value 6 in intTable.
cout << " n Searching for 6 in intTable. $\mathrm{nn}^{\prime}$;
result $=$ intTable.findItem(6);
if (result == -1)
cout << " 6 was not found in intTable. In";
else
cout << " 6 was found at subscript " << result << end1;
// Search for the value 12.84 in doubleTable.
cout << " $\backslash n$ Searching for 12.84 in doubleTable. $1 \mathrm{n} " ;$
result $=$ doubleTable.findItem(12.84);
if (result == -1)
cout << "12.84 was not found in doubleTable. $1 \mathrm{n} "$;
e1se
cout << " 12.84 was found at subscript " << result << end1;
return 0;

## Program Output

These values are in intTable:
0246681012141618
These values are in doubleTable:
$02.144 .286 .428 .5610 .712 .8414 .98 \quad 17.1219 .26$
Searching for 6 in intTable.
6 was found at subscript 3
Searching for 12.84 in doubleTable.
12.84 was found at subscript 6

The SearchableVector class demonstrates that a class template may be derived from another class template. In addition, class templates may be derived from ordinary classes, and ordinary classes may be derived from class templates.

## Specialized Templates

Suppose you have a template that works for all data types but one. For example, the SimpleVector and SearchableVector classes work well with numeric data, and even character data. But they will not work with C-strings. Situations like this require the use of specialized templates. A specialized template is one that is designed to work with a specific data type. In the declaration, the actual data type is used instead of a type parameter. For example, the declaration of a specialized version of the SimpleVector class might start like this:

```
class SimpleVector<char *>
```

The compiler would know that this version of the SimpleVector class is intended for the char * data type. Anytime an object is defined of the type SimpleVector <char *>, the compiler will use this template to generate the code.

## Checkpoint

16.10 Suppose your program uses a class template named List, which is defined as
template<class T>
class List
\{
// Members are declared here...
\};

Give an example of how you would use int as the data type in the definition of a List object. (Assume the class has a default constructor.)
16.11 As the following Rectang1e class is written, the width and 1 ength members are doubles. Rewrite the class as a template that will accept any data type for these members.

```
class Rectangle
{
    private:
            double width;
            double length;
        public:
            void setData(double w, double 1)
                    { width = w; length = 1;}
            double getWidth()
                    { return width; }
            double getLength()
                    { return length; }
            double getArea()
                    { return width * length; }
};
```

## Review Questions and Exercises

## Short Answer

1. What is a throw point?
2. What is an exception handler?
3. Explain the difference between a try block and a catch block.
4. What happens if an exception is thrown, but not caught?
5. What is "unwinding the stack"?
6. What happens if an exception is thrown by a class's member function?
7. How do you prevent a program from halting when the new operator fails to allocate memory?
8. Why is it more convenient to write a function template than a series of overloaded functions?
9. Why must you be careful when writing a function template that uses operators such as [] with its parameters?

## Fill-in-the-Blank

10. A value or object that signals an error is called $\qquad$ .
11. When a throw statement executes, the control of the program passes on to a part of the program that is called $\qquad$ .
12. The keywords used in $\mathrm{C}++$ to handle exceptions are $\qquad$ , , and
$\qquad$ .
13. When writing function or class templates, you use $a(n)$ $\qquad$ to specify a generic data type.
14. The beginning of a template is marked by a(n) $\qquad$ .
15. When defining objects of class templates, the $\qquad$ you wish to pass into the type parameter must be specified.
16. A(n) $\qquad$ template works with a specific data type.

## Algorithm Workbench

17. Write a function that searches a numeric array for a specified value. The function should return the subscript of the element containing the value if it is found in the array. If the value is not found, the function should throw an exception.
18. Write a function that dynamically allocates a block of memory and returns a char pointer to the block. The function should take an integer argument that is the amount of memory to be allocated. If the new operator cannot allocate the memory, the function should return a null pointer.
19. Make the function you wrote in Question 17 a template.
20. Write a function template that interchanges two values of variables of any type.

## True or False

21. T F There can be only one catch block in a program.
22. T F An exception class generally has no code in its body.
23. T F When an exception is thrown outside a try block, the exception will cause the entire program to abort execution.
24. T F If a function call throws an exception, the statements following it within the try block are skipped.
25. T F All type parameters defined in a function template must appear at least once in the function parameter list.
26. T F The compiler creates an instance of a function template in memory as soon as it encounters the template.
27. T F A class object passed to a function template must overload any operators used on the class object by the template.
28. T F A template class is a class that generates identical objects.
29. T F In the function template definition, it is not necessary to use each type parameter declared in the template prefix.
30. T F Function templates support overriding but not overloading.
31. T F It is possible to overload a function template and an ordinary (nontemplate) function.
32. T F Class templates cannot be publicly inherited.
33. T F A class template may not be used as a base class.
34. T F Specialized templates work with a specific data type.

## Find the Error

Each of the following declarations or code segments has errors. Locate as many as possible.

```
35. catch
    {
        quotient = divide(num1, num2);
        cout << "The quotient is " << quotient << endl;
    }
    try (string exceptionString)
    {
        cout << exceptionString;
    }
36. try
    {
        throw "Error: Unknown error";
        cout << "No error here" << endl;
    }
    catch ()
    {
        cout << "Error caught" << endl;
    }
37. template <class T>
    void (T number)
    {
    cout << T;
}
```

```
38. template <class T>
    int square(int number)
    {
    return number * number;
    }
39. template <class T1, class T2>
    T1 sum(T1 x, T1 y)
    {
        return x + y;
    }
```

40. Assume the following definition appears in a program that uses the SimpleVector class template presented in this chapter.
int <SimpleVector> array (25);
41. Assume the following statement appears in a program that has defined valueSet as an object of the SimpleVector class presented in this chapter. Assume valueSet is a vector of ints, and has 20 elements.
cout << valueSet<int>[2] << endl;

## Programming Challenges

## 1. Date Exceptions

Modify the Date class you wrote for Programming Challenge 1 of Chapter 13 (Date). The class should implement the following exception classes:

InvalidDay Throw when an invalid day $(<1$ or $>31)$ is passed to the class.
InvalidMonth Throw when an invalid month $(<1$ or $>12)$ is passed to the class.
Demonstrate the class in a driver program.

## 2. Time Format Exceptions

Modify the MilTime class you created for Programming Challenge 4 of Chapter 15 (Time Format). The class should implement the following exceptions:
BadHour Throw when an invalid hour $(<0$ or $>2359$ ) is passed to the class.
BadSeconds Throw when an invalid number of seconds $(<0$ or $>59)$ is passed to the class.

Demonstrate the class in a driver program.

## 3. Multiple Parameter Templates

Write a template function named showValues. The function should accept two arguments of two different generic data types. It should then display the value of each argument and the amount of memory space it occupies in bytes. Design a simple driver program that demonstrates the templates with the following data types: int, float, char, char *, and long double.
4. Function Template arrange

Write a function template named arrange. The function should accept three reference variables as arguments and arrange them in ascending order. Design a simple driver program that demonstrates the template with int, double, and char data types.

## 5. Function Template to Return Sum of Squares of an Array

Write a function template that computes the sum of squares of all the elements in an array. The function should accept the array and its size as arguments. The elements and size of the array should be of generic and integer data types, respectively. Test the template in a simple driver program that sends values of various types as arguments and displays the results.

## 6. IntArray Class Exception

Chapter 14 presented an IntArray class that dynamically creates an array of integers and performs bounds checking on the array. If an invalid subscript is used with the class, it displays an error message and aborts the program. Modify the class so it throws an exception instead.

## 7. Chess Movement

In chess, the knight can move either two squares horizontally and one square vertically or two squares vertically and one square horizontally. Write a Knight class that contains the current position of the knight. The class should have a member function to move the knight. The function should throw an exception when an invalid move is requested.

## 8. SimpleVector Modification

Modify the SimpleVector class template presented in this chapter to include the member functions push_back and pop_back. The push_back function should accept an argument and insert its value at the end of the array. The pop_back function should accept no argument and remove the last element from the array. Test the class with a driver program.

## 9. SearchableVector Modification

Modify the SearchableVector class template presented in this chapter so it performs a binary search instead of a linear search. Test the template in a driver program.

## 10. Class Template Cuboid

Design a class template Cuboid that should have member variables length, breadth, and height. It should have the member functions getVolume and getSurfaceArea. Test the class using a driver program. Note that a cuboid of sides $a, b$, and $c$ has volume $V=a \times b \times c$ and surface area $A=2(a b+b c+c a)$.

## 11. Inheritance Modification

Assuming you have completed Programming Challenges 9 and 10, modify the inheritance hierarchy of the SearchableVector class template so it is derived from the SortableVector class instead of the SimpleVector class. Implement a member function named sortAndSearch, both a sort and a binary search.

## 12. Specialized Templates

In this chapter, the section Specialized Templates within Section 16.4 describes how to design templates that are specialized for one particular data type. The section introduces a method for specializing a version of the SimpleVector class template so it will work with strings. Complete the specialization for both the SimpleVector and SearchableVector templates. Demonstrate them with a simple driver program.

## 13. Exception Project

This assignment assumes you have completed Programming Challenge 1 of Chapter 15 (Employee andProductionWorker Classes). Modify the Employee and ProductionWorker classes so they throw exceptions when the following errors occur:

- The Employee class should throw an exception named InvalidEmployeeNumber when it receives an employee number that is less than 0 or greater than 9999.
- The ProductionWorker class should throw an exception named InvalidShift when it receives an invalid shift.
- The ProductionWorker class should throw an exception named InvalidPayRate when it receives a negative number for the hourly pay rate.
Write a driver program that demonstrates how each of these exception conditions works.

### 17.1 Introduction to the Standard Template Library

CONCEPT: The Standard Template Library is an extensive collection of templates for useful data structures and algorithms.

In addition to its runtime library, which you have used throughout this book, $\mathrm{C}++$ also provides an extensive library of templates. The Standard Template Library (or STL) contains numerous generic templates for classes and functions. Most of the templates in the STL can be grouped into the following categories:

- Containers: Class templates for objects that store and organize data
- Iterators: Class templates for objects that behave like pointers, and are used to access the individual data elements in a container
- Algorithms: Function templates that perform various operations on elements of containers

This chapter introduces many of the STL's class and function templates.

### 17.2 STL Container and Iterator Fundamentals

CONCEPT: A container is an object that holds a collection of values or other objects. An iterator is an object that is used to iterate over the items in a collection, providing access to them.

## Containers

There are two types of container classes in the STL: sequence and associative. A sequence container stores its data sequentially in memory, in a fashion similar to an array. An associative container stores its data in a nonsequential way that makes it faster to locate elements.

The sequence containers currently provided in the STL are listed in Table 17-1. (Note that the deque container will be discussed in Chapter 19, and the list and forward_list containers will be discussed in Chapter 18.)

Table 17-1 Sequence Containers

| Container Class | Description |
| :--- | :--- |
| array | A fixed-size container that is similar to an array <br> A double-ended queue. Like a vector, but designed so that values can be <br> quickly added to or removed from the front and back. (This container will <br> be discussed in Chapter 19.) |
| forward_list | A singly linked list of data elements. Values may be inserted to or removed <br> from any position. (This container will be discussed in Chapter 18.) |
| list | A doubly linked list of data elements. Values may be inserted to or removed <br> from any position. (This container will be discussed in Chapter 18.) |
| vector | A container that works like an expandable array. Values may be added to <br> or removed from a vector. The vector automatically adjusts its size to <br> accommodate the number of elements it contains. |

The associative containers currently provided in the STL are listed in Table 17-2.

## Table 17-2 Associative Containers

| Container Class | Description |
| :--- | :--- |
| set | Stores a set of unique values that are sorted. No duplicates are allowed. <br> multiset <br> map |
| Stores a set of unique values that are sorted. Duplicates are allowed. <br> Maps a set of keys to data elements. Only one key per data element <br> is allowed. Duplicates are not allowed. The elements are sorted in <br> order of their keys. <br> Maps a set of keys to data elements. Many keys per data element <br> are allowed. Duplicates are allowed. The elements are sorted in <br> order of their keys. |  |
| unordered_set | Like a set, except that the elements are not sorted |
| unordered_multiset | Like a multiset, except that the elements are not sorted <br> unordered_map |
| Like a map, except that the elements are not sorted |  |

In addition to the classes listed in Tables 17-1 and 17-2, the STL also provides the three container adapter classes listed in Table 17-3. A container adapter class is not itself a container,
but a class that adapts one of the other containers to a specific use. Note we will discuss these classes in Chapter 19.

Table 17-3 Container Adapter Classes

| Container Adapter Class | Description |
| :--- | :--- |
| stack | An adapter class that stores elements in a deque (by default). A <br> stack is a last-in, first-out (LIFO) container. When you retrieve an <br> element from a stack, the stack always gives you the last element <br> that was inserted. (This class will be discussed in Chapter 19.) |
| queue | An adapter class that stores elements in a deque (by default). A queue <br> is a first-in, first-out (FIFO) container. When you retrieve an element <br> from a stack, the stack always gives you the first, or earliest, element <br> that was inserted. (This class will be discussed in Chapter 19.) |
| priority_queue | An adapter class that stores elements in a vector (by default). A <br> data structure in which the element that you retrieve is always the <br> element with the greatest value. (This class will be discussed in <br> Chapter 19.) |

The container and container adapter classes are declared in various STL header files. Table 17-4 lists the necessary header files that you will need to include, depending on the containers you intend to use.

Table 17-4 Header Files

| Header File | Classes |
| :--- | :--- |
| <array> | array |
| <deque> | deque |
| <forward_1ist> | forward_1ist |
| <list> | list |
| <map> | map, multimap |
| <queue> | queue, priority_queue |
| <set> | set, multiset |
| <stack> | stack |
| <unordered_map> | unordered_map, unordered_multimap |
| <unordered_set> | unordered_set, unordered_multiset |
| <vector> | vector |

## Introduction to the array Class

Perhaps the simplest container in the STL is the array class, which was introduced in C++ 11. An array object works very much like a regular array. It is a fixed-size container that holds elements of the same data type. In fact, an array object uses a traditional array, internally, to store its elements. An advantage array objects have over regular arrays is that array objects have a size() member function that returns the number of elements contained in the object.

When you define an array object, you must specify the data type of its elements, and the number of elements the object will store. Here is an example:

```
array<int, 5> numbers;
```

This statement defines an array object named numbers. Inside the angled brackets <>, the data type int is the type of each element, and the value 5 is the number of elements the object will have. You can provide an initialization list to initialize an array, as shown here:

```
array<int, 5> numbers = {1, 2, 3, 4, 5};
```

Here is an example of defining an array to hold four strings:

```
array<string, 4> names = {"Jamie", "Ashley", "Doug", "Claire"};
```

The array class overloads the [] operator, giving you the ability to access elements using a subscript, just as you would with a regular array. Program 17-1 gives a simple demonstration of creating and initializing an array object, and displaying its elements.

## Program 17-1

```
#include <iostream>
#include <string>
#include <array>
using namespace std;
int main()
{
    const int SIZE = 4;
    // Store some names in an array object.
    array<string, SIZE> names = {"Jamie", "Ashley", "Doug", "Claire"};
    // Display the names.
    cout << "Here are the names:\n";
    for (int index = 0; index < names.size(); index++)
        cout << names[index] << endl;
    return 0;
}
```

## Program Output

Here are the names:
Jamie
Ashley
Doug
Claire
Take a closer look at the following lines of code in Program 17-1:

- The statement in line 11 defines an array object named names, initialized with four strings.
- The for loop in lines 15 and 16 displays all of the strings. Notice the array object's size() member function is used in the loop's test expression.
- In line 16, the [] operator is used to access the object's elements.

The for loop in lines 15 and 16 of Program 17-1 is useful to demonstrate the use of the array class's size() member function, but we could easily rewrite it as a range-based for loop.

```
for (auto element : names)
    cout << element << endl;
```

WARNING! The array class's [] operator does not perform bounds checking. As with regular arrays, you must be careful not to use a subscript that is out of bounds with an array object.

As you can see, the array class is an object-oriented alternative to a traditional array in C++. The array class also provides several member functions that give additional capabilities. Table 17-5 lists the array class's member functions.

Table 17-5 The array Member Functions

| Member Function | Description |
| :---: | :---: |
| at (index) | Returns a reference to the element located at the specified index. If the specified index is out of bounds, the at function throws an out_of_bounds exception. |
| back() | Returns a reference to the last element in the container. |
| begin() | Returns an iterator to the first element in the container. |
| cbegin() | Returns a const_iterator to the first element in the container. |
| cend() | Returns a const_iterator pointing to the end of the container. |
| crbegin() | Returns a const_reverse_iterator pointing to the last element in the container. |
| crend() | Returns a const_reverse_iterator pointing to the first element in the container. |
| data() | Returns a pointer to the first element in the container. The array class uses a traditional array to store its data, so the pointer returned from the data() function points to the first element in the underlying array. |
| empty () | Returns true if the container is empty, or false otherwise. |
| end() | Returns an iterator pointing to the end of the container. |
| fill(value) | Sets the value of each element to value. |
| front() | Returns a reference to the first element in the container. |
| max_size() | Returns the number of elements in the container (the same value returned by the size() member function). |
| rbegin() | Returns a reverse_iterator pointing to the last element in the container. |
| rend() | Returns a reverse_iterator pointing to the first element in the container. |
| size() | Returns the number of elements in the container. |
| swap (second) | The second argument must be an array object of the same type and size as the calling object. The function swaps the contents of the calling object and the second object. |

Notice many of the member functions listed in Table 17-5 return iterators. Iterators are a fundamental part of the STL, so it is important to have an understanding of them.

## Iterators

Iterators are objects that work like pointers, and are used to access data stored in containers. As the name implies, you can use an iterator to iterate over the contents of a container. There are currently five categories of iterators, as described in Table 17-6. ${ }^{1}$

## Table 17-6 Categories of Iterators

| Iterator Category | Description |
| :--- | :--- |
| Forward | Can only move forward in a container (uses the ++ operator). |
| Bidirectional | Can move forward or backward in a container (uses the ++ and -- operators). <br> Random access |
| Can move forward and backward, and can jump to a specific data element <br> in a container. |  |
| Input | Can be used with an input stream to read data from an input device or a file. <br> Output |
| Can be used with an output stream to write data to an output device or a file. |  |

Iterators are associated with containers. The type of container you have determines the category of iterator you use. For example:

- The array, vector, and deque containers use random-access iterators.
- The list, set, multiset, map, and multimap containers use bidirectional iterators.
- The forward_list, unordered_map, unordered_multimap, unordered_set, and unordered_multiset containers use forward iterators.

Iterators are like pointers in the following ways:

- An iterator can point to an element in a container.
- You can use the * operator to dereference an iterator, getting the element that it points to.
- When an iterator points to an object, you can use the -> operator to access the object's members.
- You can use the $=$ operator to assign an iterator to an element.
- You can use the $==$ and != operators to compare two iterators.
- You can use the ++ operator to increment an iterator, thus moving it to the next element in the container. You can also use the + operator to add an integer to an iterator, thus moving it forward in the container by a number of elements.
- If you are using a bidirectional or random-access iterator, you can use the -- operator to decrement the iterator, thus moving it to the previous element in the container. You can also use the - operator to subtract an integer from an iterator, thus moving it backward in the container by a number of elements.

## Defining an Iterator

Before you can define an iterator, you have to know the type of container with which you want to use the iterator. The general format of an iterator definition is:

```
containerType::iterator iteratorName;
```

[^5]In the general format, containerType is the STL container type, and iteratorName is the name of the iterator variable that you are defining. For example, suppose we have defined an array object, as follows:

```
array<string, 3> names = {"Sarah", "William", "Alfredo"};
```

We can define an iterator that will work with the array object with the following statement:

```
array<string, 3>::iterator it;
```

This statement defines an iterator named it, that can be used with an array<string, 3> object. The compiler automatically chooses the right type of iterator (in this case, a ran-dom-access iterator).

## Getting an Iterator from a Container Object

All of the container classes in the STL provide a begin() member function and an end() member function. The begin() member function is straightforward: It returns an iterator pointing to the first element in a container. For example, the following code snippet does the following:

1. It defines an array object initialized with three strings.
2. It defines an iterator that can be used with the array object.
3. It makes the iterator point to the first element in the array object.
4. It uses the * operator to dereference the iterator, and displays the element to which the iterator points.
```
// Define an array object. (1)
array<string, 3> names = {"Sarah", "William", "Alfredo"};
// Define an iterator for the array object. (2)
array<string, 3>::iterator it;
// Make the iterator point to the array object's first element. (3)
it = names.begin();
// Display the element that the iterator points to. (4)
cout << *it << endl;

The end() member function returns an iterator pointing to the position after the last element. This means it returns an iterator that does not point to an element, but points to the end of the container. This is illustrated in Figure 17-1.

Figure 17-1 Iterators returned from the begin() and end () member functions

You typically use the end () member function to know when you have reached the end of a container in algorithms that iterate over a range of elements. For example, the following
code snippet shows an iterator being used with a while loop to display the contents of an array object:
```

// Define an array object.
array<string, 3> names = {"Sarah", "William", "Alfredo"};
// Define an iterator for the array object.
array<string, 3>::iterator it;
// Make the iterator point to the array object's first element.
it = names.begin();
// Display the array object's contents.
while (it != names.end())
{
cout << *it << endl;
it++;
}

```

The code previously shown could be shortened somewhat by using a for loop instead of a while loop. Program 17-2 shows an example.

\section*{Program 17-2}
```

\#include <iostream>
\#include <string>
\#include <array>
using namespace std;
int main()
{
const int SIZE = 3;
// Store some names in an array object.
array<string, SIZE> names = {"Sarah", "William", "Alfredo"};
// Create an iterator for the array object.
array<string, SIZE>::iterator it;
// Display the names.
cout << "Here are the names:\n";
for (it = names.begin(); it != names.end(); it++)
cout << *it << endl;
return 0;
}

```

\section*{Program Output}

Here are the names:
Sarah
William
Alfredo

\section*{Using auto to Define an Iterator}

Quite often, you can use auto to simplify the definition of an iterator. For example, any time you are initializing an iterator with the value that is returned from a member function, such as begin(), you can use auto in the iterator's declaration. For example, look at the following code:
```

array<string, 3> names = {"Sarah", "William", "Alfredo"};
array<string, 3>::iterator it = names.begin();

```

The second statement defines an iterator named it, and calls the names.begin() member function to initialize it. This statement can be rewritten, as shown in the following code:
```

array<string, 3> names = {"Sarah", "William", "Alfredo"};
auto it = names.begin();

```

The auto declaration shown in the second statement works because the names.begin() function returns an object of the array<string, 3>::iterator type. So, the compiler can determine that it should be an object of the array<string, 3>::iterator type. This is especially useful in for loops that use iterators to step through the elements of a container. For example, look at Program 17-3. It is similar to Program 17-2, but in this version, the iterator is auto declared in the initialization expression of the for loop (in line 15).

\section*{Program 17-3}
```

\#include <iostream>
\#include <string>
\#include <array>
using namespace std;
int main()
{
const int SIZE = 4;
// Store some names in an array object.
array<string, SIZE> names = {"Jamie", "Ashley", "Doug", "Claire"};
// Display the names.
cout << "Here are the names:\n";
for (auto it = names.begin(); it != names.end(); it++)
cout << *it << endl;
return 0;
}

```

\section*{Program Output}

Here are the names:
Sarah
William
Alfredo

\section*{Mutable Iterators and const_iterators}

An iterator of the iterator type gives you read/write access to the element to which the iterator points. This is commonly known as a mutable iterator. The following code snippet shows an example:
```

// Define an array object.
array<int, 5> numbers = {1, 2, 3, 4, 5};
// Define an iterator for the array object.
array<int, 5>::iterator it;
// Make the iterator point to the array object's first element.
it = numbers.begin();
// Use the iterator to change the element.
*it = 99;

```

In this code snippet, the numbers object initially contains the values \(1,2,3,4\), and 5 . The last statement dereferences the it iterator (which points to the first element) and changes the element's value to 99 . After the last statement executes, the numbers object contains the values \(99,2,3,4\), and 5 .
If you want to make sure that nothing changes the contents of a container, you can use the const modifier with the container definition to make the container's contents constant. Here is an example:
```

const array<string, 3> names = {"Sarah", "William", "Alfredo"};

```

This statement defines names as a const array object. As a result, the elements in the container are constant, and cannot be modified. (Attempting to modify the container's contents will result in an error at compile time.) If we need an iterator to work with the object, we must use a const_iterator, which provides read-only access to any element to which it points. The following statement shows an example of how to define a const_iterator:
```

array<string, 3>::const_iterator it;

```

All of the container classes in the STL provide a cbegin() member function and a cend() member function. The cbegin() member function returns a const_iterator pointing to the first element in a container. The cend() member function returns a const_iterator pointing to the end of the container. When working with const_iterators, simply use the container class's cbegin() and cend() member functions instead of the begin() and end () member functions.

\section*{Reverse Iterators}

A reverse iterator is a bidirectional or random-access iterator that works in reverse, allowing you to iterate backward over the elements in a container. When using a reverse iterator, the last element in a container is considered the first element, and the first element is considered the last element. The ++ operator moves a reverse iterator backward, and the -- operator moves a reverse iterator forward.

The following STL containers support the use of reverse iterators: array, deque, list, map, multimap, multiset, set, and vector. All of these classes provide an rbegin() member function and an rend () member function. The rbegin() member function returns a reverse iterator pointing to the last element in a container, and the rend () member function returns an iterator pointing to the position before the first element. This is illustrated in Figure 17-2.

Figure 17-2 Iterators returned by the rbegin() and rend () member functions

To create a reverse iterator, you define it as reverse_iterator. The following code snippet shows an example of using a reverse iterator to display the contents of an array object in reverse order:
```

// Define an array object.
array<int, 5> numbers = {1, 2, 3, 4, 5};
// Define a reverse iterator for the array object.
array<int, 5>::reverse_iterator it;
// Display the elements in reverse order.
for (it = numbers.rbegin(); it != numbers.rend(); it++)
cout << *it << endl;

```

Iterators that are declared as reverse_iterator are mutable, meaning they give you read/ write access to the element being pointed to. If you need a reverse iterator to work with a const container, you must use a const_reverse_iterator, which provides read-only access to any element that it points to. The following code shows an example of how to create a const_reverse_iterator:
```

const array<string, 3> names = {"Sarah", "William", "Alfredo"};
array<string, 3>::const_reverse_iterator it;

```

Each of the STL container classes that supports reverse iterators provides a crbegin() member function and a crend() member function. The crbegin() member function returns a const_reverse_iterator pointing to the last element in the container. The crend() member function returns a const_reverse_iterator pointing to the position before the first element in the container.

\section*{Checkpoint}
17.1 What two types of containers does the STL provide?
17.2 What is a container adapter class?
17.3 What is an iterator?
17.4 Suppose you are writing a program that uses the array, multimap, and vector classes. What header files must you \#include in the program, in order to use these classes?
17.5 What is the difference between a bidirectional iterator and a random-access iterator?
17.6 What does the ++ operator do when applied to an iterator?
17.7 What does a container's begin() and end () member functions return?
17.8 What is the difference between a mutable iterator and a const_iterator?
17.9 What is a reverse iterator?
17.10 What does a container's rbegin() and rend() member functions return?

\subsection*{17.3 The vector Class \\ CONCEPT: A vector is a sequence container that works like an array, but is dynamic in size.}

VideoNote
The vector Container

Chapter 7 introduces the vector class and discusses several of the class's member functions. In this section, we will take a closer look at the class, and discuss how to use iterators to access a vector container's elements.

Recall from our previous discussions that a vector stores a sequence of elements, like an array. In fact, a vector uses an array internally to store its elements. A vector, however, offers many advantages over an array:
- You do not have to declare the size of a vector when you define it.
- A vector is dynamic in size. You can add elements to it, or delete elements from it at runtime. The vector automatically adjusts its size according to the number of elements it contains.
- A vector can report the number of elements it contains.

To use the vector class, you need to \#include the <vector> header file in your program. Then, you can define a vector object using one of the four vector constructors. Table 17-7 shows the general format of a vector definition statement using each constructor. Table 17-8 lists most of the vector class's member functions.

Table 17-7 vector Definition Statements

\section*{Default Constructor vector<dataType> name;}

Creates an empty vector object. In the general format, dataType is the data type of each element, and name is the name of the vector.
Fill Constructor vector<dataType> name(size);
Creates a vector object of a specified size. In the general format, dataType is the data type of each element, and name is the name of the vector. The size argument is an unsigned integer that specifies the number of elements that the vector should initially have. If the elements are objects, they are initialized via their default constructors. Otherwise, the elements are initialized with the value 0 .
Fill Constructor vector<dataType> name(size, value);
Creates a vector object of a specified size, where each element is initially given a specified value. In the general format, dataType is the data type of each element, and name is the name of the vector. The size argument is an unsigned integer that specifies the number of elements that the vector should initially have, and the value argument is the value with which to fill each element.

Table 17-7 (continued)
\begin{tabular}{ll}
\hline Range Constructor & \begin{tabular}{l} 
vector<dataType> name(iterator1, iterator2) ; \\
Creates a vector object that initially contains a range of values specified \\
by two iterators. In the general format, dataType is the data type of \\
each element, and name is the name of the vector. The iterator1 and \\
iterator2 arguments mark the beginning and end of a range of values \\
that will be stored in the vector.
\end{tabular} \\
Copy Constructor \begin{tabular}{l} 
vector<dataType> name(vector2) ; \\
Creates a vector object that is a copy of another vector or object. In the \\
general format, dataType is the data type of each element, name is the name \\
of the vector, and vector2 is the vector to copy.
\end{tabular}
\end{tabular}

Table 17-8 The vector Member Functions
\begin{tabular}{|c|c|}
\hline Member Function & Description \\
\hline assign(size, value) & Assigns a new set of elements to the container, replacing its existing elements. The size argument is an unsigned integer that specifies the number of elements that the vector should have, and the value argument is the value with which to fill each element. After the function executes, the container will have size elements, each set to value. \\
\hline assign(iterator1, iterator2) & Assigns a new set of elements to the container, replacing its existing contents with a range of values specified by iterators. The iterator 1 and iterator2 arguments mark the beginning and end of a range of values that will be stored in the container. \\
\hline at (index) & The index argument is an unsigned integer. The function returns a reference to the element located at the specified index. (The first element is at index 0 , the second element is at index 1 , and so on.) If the specified index is out of bounds, the at function throws an out_of_bounds exception. \\
\hline back() & Returns a reference to the last element in the container. \\
\hline begin() & Returns an iterator to the first element in the container. \\
\hline capacity () & Returns the number of elements that the container's underlying array can hold without reallocating the array. \\
\hline cbegin() & Returns a const_iterator to the first element in the container. \\
\hline cend() & Returns a const_iterator pointing to the end of the container. \\
\hline clear () & Erases all of the elements in the container. \\
\hline crbegin() & Returns a const_reverse_iterator pointing to the last element in the container. \\
\hline crend() & Returns a const_reverse_iterator pointing to the first element in the container. \\
\hline data() & Returns a pointer to the first element in the container. The vector class uses a traditional array to store its data, so the pointer returned from the data() function points to the first element in the underlying array. \\
\hline
\end{tabular}

Table 17-8 (continued)
\begin{tabular}{|c|c|}
\hline Member Function & Description \\
\hline emplace(it, value) & Constructs a new element with value as its value. The it argument is an iterator pointing to an existing element in the container. The new element will be inserted before the one pointed to by it. \\
\hline emplace_back(value) & Constructs a new element containing the specified value at the end of the container. \\
\hline empty () & Returns true if the container is empty, or false otherwise. \\
\hline end() & Returns an iterator pointing to the end of the container. \\
\hline erase(it) & Erases the element pointed to by the iterator \(i t\). This function returns an iterator pointing to the element that follows the removed element (or the end of the container, if the removed element was the last one). \\
\hline \begin{tabular}{l}
erase(iterator1, \\
iterator2)
\end{tabular} & Erases a range of elements. The iterator1 and iterator2 arguments mark the beginning and end of a range of values that will be erased. This function returns an iterator pointing to the element that follows the removed elements (or the end of the container, if the last element was erased). \\
\hline front () & Returns a reference to the first element in the container. \\
\hline insert(it, value) & Inserts a new element with value as its value. The it argument is an iterator pointing to an existing element in the container. The new element will be inserted before the one pointed to by \(i t\). The function returns an iterator pointing to the newly inserted element. \\
\hline insert(it, n, value) & Inserts \(n\) new elements with value as their value. The it argument is an iterator pointing to an existing element in the container, and \(n\) is an unsigned integer. The new elements will be inserted before the one pointed to by \(i t\). The function returns an iterator pointing to the first element of the newly inserted elements. \\
\hline \begin{tabular}{l}
insert(iterator1, \\
iterator2, \\
iterator3)
\end{tabular} & Inserts a range of new elements. The iterator 1 argument points to an existing element in the container. The range of new elements will be inserted before the element pointed to by iterator1. The iterator2 and iterator3 arguments mark the beginning and end of a range of values that will be inserted. (The element pointed to by iterator 3 will not be included in the range.) The function returns an iterator pointing to the first element of the newly inserted range. \\
\hline max_size() & Returns the theoretical maximum size of the container. \\
\hline pop_back() & Removes the last element of the container. \\
\hline push_back(value) & Adds a new element containing value to the end of the container. \\
\hline rbegin() & Returns a reverse_iterator pointing to the last element in the container. \\
\hline rend() & Returns a reverse_iterator pointing to the first element in the container. \\
\hline resize(n) & The \(n\) argument is an unsigned integer. This function resizes the container so it has \(n\) elements. If the current size of the container is larger than \(n\), then the container is reduced in size so it keeps only the first \(n\) elements. If the current size of the container is smaller than \(n\), then the container is increased in size so it has \(n\) elements. \\
\hline
\end{tabular}

Table 17-8 (continued)
\begin{tabular}{ll}
\hline Member Function & Description \\
\hline resize( \(n\), value) & \begin{tabular}{l} 
Resizes the container so it has \(n\) elements (the \(n\) argument is an \\
unsigned integer). If the current size of the container is larger than \(n\), \\
then the container is reduced in size so it keeps only the first \(n\) \\
elements. If the current size of the container is smaller than \(n\), then \\
the container is increased in size so that it has \(n\) elements, and each of \\
the new elements is initialized with value.
\end{tabular} \\
shrink_to_fit() & \begin{tabular}{l} 
Requests that the vector be resized so its capacity is the same as its size. \\
Rize() \\
Rwap(second)
\end{tabular} \\
\begin{tabular}{l} 
Returns the number of elements in the container. \\
The second argument must be a vector object of the same type \\
as the calling object. The function swaps the contents of the calling \\
object and the second object.
\end{tabular}
\end{tabular}

\section*{Review of Basic vector Operations}

Here is an example of how you would use the default constructor to define a vector container to hold integers:
```

vector<int> numbers;

```

This statement defines an empty vector container named numbers. Inside the angled brackets <>, the data type int is the type of each element. If you are using a compiler that is compliant with \(\mathrm{C}++11\) or later, you can use an initialization list to initialize the vector, as shown here:
```

vector<int> numbers = {1, 2, 3, 4, 5};

```

Here is an example of defining a vector to hold strings:
```

vector<string> names = {"Joe", "Karen", "Lisa", "Jackie"};

```

The vector class overloads the [] operator, giving you the ability to access elements using a subscript, just as you would with an array. Program 17-4 gives a simple demonstration of creating and initializing a vector object, and displaying its elements.

\section*{Program 17-4}
```

\#include <iostream>
\#include <vector>
using namespace std;
int main()
{
const int SIZE = 10;
// Define a vector to hold 10 int values.
vector<int> numbers(SIZE);

```
```

Program 17-4 (continued)
12 // Store the values 0 through 9 in the vector.
13 for (int index = 0; index < numbers.size(); index++)
14 numbers[index] = index;
15
16
17
18
19
20
21 return 0;
22 }

```

\section*{Program Output}
```

0 1 2 3 4 5 6 7 8 9

```

Keep in mind the [] operator has its limitations. Specifically, you can use it only to access elements that already exist in a vector. In other words, you cannot add new elements to an existing vector using the [] operator. For example, the following code will cause an error at run time:
```

vector<int> numbers; // Define an empty vector
numbers[0] = 99; // Error!

```

This code will cause an error because numbers is an empty vector. Therefore, the element numbers[0] does not exist. If you want to add new elements to a vector, you must use one of the member functions that exist for that purpose in the vector class. For example, the push_back() member function adds a new element to the end of the container. You simply call the function, passing the new element's value as an argument. The following code shows an example:
```

vector <int> numbers;
numbers.push_back(10);
numbers.push_back(20);
numbers.push_back(30);

```

The first statement creates an empty vector container named numbers. The statements that follow add the values 10,20 , and 30 to the vector.

You can use the at() member function to retrieve a vector element by its index with bounds checking. The following code shows an example:
```

vector<string> names = {"Joe", "Karen", "Lisa"};
cout << names.at(3) << endl; // Throws an exception

```

The first statement in this code snippet defines a vector with three elements: "Joe" is at index 0 , "Karen" is at index 1 , and "Lisa" is at index 2 . The second statement tries to display the element at index 3 , which does not exist. As a result, the at () member function throws an out_of_bounds exception.

\section*{Using an Iterator with a vector}

The vector class supports the use of iterators of the following types:
- iterator
- const_iterator
- reverse_iterator
- const_reverse_iterator

Notice in Table 17-8 the vector class provides the following member functions for getting iterators: begin(), end (), cbegin(), cend(), rbegin(), rend(), crbegin(), and crend().

The following code shows an example of using an iterator to display all of the elements of a vector:
```

// Create a vector containing names.
vector<string> names = {"Joe", "Karen", "Lisa", "Jackie"};
// Create an iterator.
vector<string>::iterator it;
// Use the iterator to display each element in the vector.
for (it = names.begin(); it != names.end(); it++)
{
cout << *it << endl;
}

```

We can simplify this code by auto declaring the iterator in the initialization expression of the for loop, as shown here:
```

// Create a vector containing names.
vector<string> names = {"Joe", "Karen", "Lisa", "Jackie"};
// Use an iterator to display each element in the vector.
for (auto it = names.begin(); it != names.end(); it++)
{
cout << *it << endl;
}

```

\section*{Inserting New Elements into a vector}

You can use the insert member function to insert one or more new elements at a specified position in a vector. There are three overloaded versions of the insert member function shown in Table 17-8. Program 17-5 shows an example of how to use the first version.

\section*{Program 17-5}
```

\#include <iostream>
\#include <vector>
using namespace std;
int main()
{
// Define a vector with 5 int values.
vector<int> numbers = {1, 2, 3, 4, 5};

```

\section*{Program 17-5 \\ (continued)}
```

1 0 ~ / / ~ D e f i n e ~ a n ~ i t e r a t o r ~ p o i n t i n g ~ t o ~ t h e ~ s e c o n d ~ e l e m e n t .
1 1
12
13
14
15
16
17
18
19
20
21 return 0;
22 }

```

\section*{Program Output}

1992345

Let's take a closer look at the program:
- Line 8 defines a vector of ints, initialized with the values \(1,2,3,4\), and 5 .
- Line 11 defines an iterator that is pointing at the second element in the vector.
- Line 14 inserts a new element just before the one that it points to. The new element contains the value 99.
- The loop in lines 17 and 18 display all of the vector's elements.

The second version of the insert member function allows you to insert multiple elements, each with the same value. The following code snippet shows an example:
```

// Define a vector with 5 int values.
vector<int> numbers = {1, 2, 3, 4, 5};
// Define an iterator pointing to the second element.
auto it = numbers.begin() + 1;
// Insert 3 new elements, each with the value 99.
numbers.insert(it, 3, 99);

```

The last statement inserts three elements, each with the value 99. After the statement executes, the vector will contain the following elements: \(\begin{array}{lllllllll}1 & 99 & 99 & 99 & 2 & 3 & 4 & 5\end{array}\)

The third version of the insert member function allows you to insert a range of elements, perhaps from a different container, into the vector. The function takes three iterators as arguments. The first iterator specifies the position where the new elements will be inserted. The second and third iterators mark the beginning and end of a range of elements to be inserted. Program 17-6 demonstrates the function by inserting a range of elements from one vector into another.

\section*{Program 17-6}
```

\#include <iostream>
\#include <vector>
using namespace std;
int main()
{
// Define two vectors.
vector<int> v1 = {1, 2, 3};
vector<int> v2 = {100, 200, 300, 400, 500};
// Define iterators
auto it1 = v1.begin() + 1; // Points at 2 in v1
auto it2 = v2.begin(); // Points at 100 in v2
auto it3 = v2.begin() + 3; // Points at 400 in v2
// Insert a range of elements into v1.
v1.insert(it1, it2, it3);
// Display the elements of v1.
for (auto element : v1)
cout << element << " ";
cout << endl;
return 0;
}

```

\section*{Program Output}

110020030023

Program 17-6 defines two vectors: v1 and v2. Line 12 defines an iterator, it1, pointing to the second element of v 1 . Line 13 defines an iterator, \(\mathrm{it2}\), pointing to the first element of v2. Line 14 defines an iterator, it 3 , pointing to the fourth element of v 2 . These iterator positions are illustrated in Figure 17-3. Then, line 17 inserts the range of elements from it2 to it3 (not including it3) into v 1 , before the element at it .

Figure 17-3 The iterators of Program 17-6

\section*{Storing Objects of Your Own Classes as Values in a vector}

In the examples previously shown, we stored strings and primitive values in vectors. It is often useful to store objects of classes that you have written in a vector. For example, the Product class, shown here, keeps information about a product. Specifically, it keeps the product's name and the number of units on hand.

\section*{Contents of Product.h}
```

\#ifndef PRODUCT_H
\#define PRODUCT_H
\#include <string>
using namespace std;
class Product
{
private:
string name;
int units;
public:
Product(string n, int u)
{ name = n;
units = u; }
void setName(string n)
{ name = n; }
void setUnits(int u)
{ units = u; }
string getName() const
{ return name; }
int getUnits() const
{ return units; }
};
\#endif

```

Program 17-7 shows how we can define and initialize a vector to hold Product objects.

\section*{Program 17-7}
```

\#include <iostream>
\#include <vector>
\#include "Product.h"
using namespace std;
int main()
{
// Create a vector of Product objects.
vector<Product> products =
{
Product("T-Shirt", 20),
Product("Calendar", 25),
Product("Coffee Mug", 30)
};

```
```

    // Display the vector elements.
    for (auto element : products)
    {
        cout << "Product: " << element.getName() << endl
        << "Units: " << element.getUnits() << endl;
    }
    return 0;
    }

```

\section*{Program Output}

Product: T-Shirt
Units: 20
Product: Calendar
Units: 25
Product: Coffee Mug
Units: 30

Program 17-8 shows an example of using the push_back member function to add Product objects to an existing vector, then using an iterator to display the contents of the vector. Notice the use of the \(->\) operator in lines 25 and 26. In those lines, it points to a Product object, so the \(\rightarrow\) operator is used to call the object's getName() and getUnits() member functions.

\section*{Program 17-8}
```

\#include <iostream>
\#include <string>
\#include <vector>
\#include "Product.h"
using namespace std;
int main()
{
// Create Product objects.
Product prod1("T-Shirt", 20);
Product prod2("Calendar", 25);
Product prod3("Coffee Mug", 30);
// Create a vector to hold the Products
vector<Product> products;
// Add the products to the vector.
products.push_back(prod1);
products.push_back(prod2);
products.push_back(prod3);

Product: Coffee Mug
Units: 30

\section*{Inserting Elements with the emplace () and emplace_back () Member Functions}

Member functions such as insert () and push_back() can cause temporary objects to be created in memory while the insertion is taking place. For programs that do not make a lot of insertions, the overhead of creating temporary objects is not usually a problem. However, for programs that insert a lot of objects into containers, member functions such as insert() and push_back() can be inefficient.

To improve runtime performance, \(\mathrm{C}++11\) introduced a new family of member functions that use a technique known as emplacement to insert new elements. The process of emplacement avoids the creation of temporary objects in memory while a new object is being inserted into a container. As a result, the emplacement functions are much more efficient than functions such as insert() and push_back(), especially when a lot of objects are being inserted into a container.

The vector class provides two member functions that use emplacement: emplace() and emplace_back().When you use one of these member functions, it is not necessary to instantiate, ahead of time, the object you are going to insert. Instead, you pass to the emplacement function any arguments that you would normally pass to the constructor of the object you are inserting. The emplacement function handles the construction of the object, forwarding the arguments to its constructor.

Program 17-9 shows an example of how we can use the emplace_back() member function to add Product objects to a vector. Notice we do not instantiate the Product class in the program. Instead, in lines 12 through 14 we pass the arguments that we would normally pass to the Product class constructor, to the emplace_back() member function. The emplace_back () member function constructs the objects in the vector. (This type of object construction is known as in-place construction.)

\section*{Program 17-9}
```

\#include <iostream>
\#include <vector>
\#include "Product.h"
using namespace std;
int main()
{
// Create a vector to hold Products.
vector<Product> products;
// Add Products to the vector.
products.emplace_back("T-Shirt", 20);
products.emplace_back("Calendar", 25);
products.emplace_back("Coffee Mug", 30);
// Use an iterator to display the vector contents.
for (auto it = products.begin(); it != products.end(); it++)
{
cout << "Product: " << it->getName() << endl
<< "Units: " << it->getUnits() << endl;
}
return 0;
}

```

\section*{Program Output}

Product: T-Shirt
Units: 20
Product: Calendar
Units: 25
Product: Coffee Mug
Units: 30

The emplace () member function constructs an object at a specified location in the vector. The first argument you pass to the emplace () member function is an iterator. The new element will be constructed at the position just before the element that the iterator points to. After the iterator, you pass the list of arguments that is to be forwarded to the new object's constructor. Program 17-10 shows an example.

\section*{Program 17-10}
```

\#include <iostream>
\#include <vector>
\#include "Product.h"
using namespace std;

```

\section*{Program 17-10 (continued)}
```

int main()
{
// Create a vector to hold Products.
vector<Product> products =
{
Product("T-Shirt", 20),
Product("Coffee Mug", 30)
};
// Get an iterator to the 2nd element.
auto it = products.begin() + 1;
// Insert another Product into the vector.
products.emplace(it, "Calendar", 25);
// Display the vector contents.
for (auto element : products)
{
cout << "Product: " << element.getName() << endl
<< "Units: " << element.getUnits() << endl;
}
return 0;
}

```

\section*{Program Output}

Product: T-Shirt
Units: 20
Product: Calendar
Units: 25
Product: Coffee Mug
Units: 30
Let's take a closer look at the program:
- Lines 9 through 13 create a vector named products, initialized with two Product objects.
- Line 16 defines an iterator, it, pointing to the second element in the vector.
- Line 19 inserts a new element into the vector, just before the element that it points to. The new element will be a Product object that is constructed, with the arguments "Calendar" and 25 passed as arguments to the constructor.

\section*{The capacity(), max_size(), shrink_to_fit(), and reserve () Member Functions}

The vector container uses a dynamically allocated array to hold its elements. When the underlying array is full, and another element is added to the vector, the vector has to increase the size of its underlying array. Typically, this means that a new array must be
allocated, all of the elements of the old array must be copied to the new array, and the old array must be deallocated.
To prevent this process from happening each time a new element is added, it is common for the vector class to allocate more memory than it needs. That way, a certain number of elements can be added without causing the reallocation process to take place. So, a vector object has two sizes: (1) the number of elements that are stored in the vector, and (2) the number of elements that can be stored in the vector without causing its underlying array to be reallocated.

You already know that the size() member function returns the number of elements that are currently stored in the vector. The vector class also has a capacity() member function that returns the number of elements that the container's underlying array can currently store, without allocating more memory. In addition, the max_size() member function returns the theoretical maximum number of elements that the vector can ever store.

The value returned from a vector's capacity () member function will always be greaterthan or equal to the value returned by the size() member function. If you need to increase a vector's capacity, you can call the reserve() member function to make the request. You pass an integer argument to specify the desired number of elements. If you need to decrease a vector's capacity, you can call the shrink_to_fit () member function to make the request. The function takes no arguments, and it simply shrinks the vector's underlying array so its capacity is the same as the vector's size.

\section*{(8) Checkpoint}
17.11 Write a statement that defines an empty vector object named avect that can hold strings.
17.12 Write a statement that defines a vector object named avect that can hold ints. The vector should have ten elements (initialized with the default value 0 ).
17.13 Write a statement that defines a vector object named avect that can hold ints. The vector should have 100 elements, each initialized with the value 1.
17.14 Write a statement that defines a vector object named v1 that can hold ints. The vector should be a copy of another vector name v 2 .
17.15 What happens when you use an invalid index with the vector class's at () member function?
17.16 What is the difference between the vector class's insert() member function and push_back () member function?
17.17 If your program will be added a lot of objects to a vector, is it best to use the inert() member function, or the emplace() member function? Why?
17.18 Internally, how does a vector store its elements?
17.19 The vector class has a size() member function and a capacity () member function. What is the difference between these two member functions?

\subsection*{17.4 The map, multimap, and unordered_map Classes}

CONCEPT: Each element in a map has two parts: a key and a value. Each key is associated with a specific value, and can be used to locate that value.

A map is an associative container. Each element that is stored in a map has two parts: a key and a value. In fact, map elements are commonly referred to as key-value pairs. When you want to retrieve a specific value from a map, you use the key that is associated with that value. This is similar to the process of looking up a word in the dictionary, where the words are keys and the definitions are values.

For example, suppose each employee in a company has an ID number, and we want to write a program that lets us look up an employee's name by entering that employee's ID number. We could create a map in which each element contains an employee ID number as the key and that employee's name as the value. This is illustrated in Figure 17-4. If we know an employee's ID number, then we can retrieve that employee's name.

Another example would be a program that lets us enter a person's name and gives us that person's phone number. The program could use a map in which each element contains a person's name as the key and that person's phone number as the value. If we know a person's name, then we can retrieve that person's phone number.

Figure 17-4 Key-value pairs

NOTE: Key-value pairs are often referred to as mappings because each key is mapped to a value.

\section*{The map Class}

The STL provides a map class template you can use to implement a map container in your programs. The map class provides many member functions for storing elements, retrieving elements, deleting elements, iterating over the map, and much more.
To use the map class, you need to \#include the <map> header file in your program. Then, you can define a map object using one of the map class constructors. Table 17-9 shows the general format of a map definition statement using each constructor. Table 17-10 lists many (but not all) of the map class's member functions.

Table 17-9 map Definition Statements
\begin{tabular}{|c|c|}
\hline \multirow[t]{2}{*}{Default Constructor} & map<keyDatatype, valueDataType> name; \\
\hline & Creates an empty map object. In the general format, keyDatatype is the data type of each element's key, valueDataType is the data type of each element's value, and name is the name of the map. \\
\hline \multirow[t]{2}{*}{Range Constructor} & map<keyDatatype, valueDataType> name(iterator1, iterator2); \\
\hline & Creates a map object that initially contains a range of values specified by two iterators. In the general format, keyDatatype is the data type of each element's key, valueDataType is the data type of each element's value, and name is the name of the map. The iterator1 and iterator2 arguments mark the beginning and end of a range of elements that will be stored in the map. \\
\hline \multirow[t]{2}{*}{Copy Constructor} & map<keyDatatype, valueDataType> name(map2) ; \\
\hline & Creates a map object that is a copy of another map or object. In the general format, keyDatatype is the data type of each element's key, valueDataType is the data type of each element's value, and name is the name of the map, and map2 is the map to copy. \\
\hline
\end{tabular}

Table 17-10 Some of the map Member Functions
\begin{tabular}{|c|c|}
\hline Member Function & Description \\
\hline at (key) & Returns a reference to the element containing the specified key. \\
\hline begin() & Returns an iterator pointing to the first element in the container. \\
\hline cbegin() & Returns a const_iterator to the first element in the container. \\
\hline cend () & Returns a const_iterator pointing to the end of the container. \\
\hline clear () & Erases all of the elements in the container. \\
\hline count (key) & Returns the number of elements containing the specified key. \\
\hline crbegin() & Returns a const_reverse_iterator pointing to the last element in the container. \\
\hline crend () & Returns a const_reverse_iterator pointing to the first element in the container. \\
\hline emplace(key, value) & Inserts a new element containing the specified key and value into the container. If an element with the specified key already exists, the function call does nothing. \\
\hline empty () & Returns true if the container is empty, or false otherwise. \\
\hline end () & Returns an iterator pointing to the end of the container (the position after the last element). \\
\hline erase(key) & Erases the element containing the specified key. The function returns 1 if the element was erased, or 0 if no matching element was found. \\
\hline find(key) & Searches for an element with the specified key. If the element is found, the function returns an iterator to it. If the element is not found, the function returns an iterator to the end of the map. \\
\hline
\end{tabular}

Table 17-10 (continued)
\begin{tabular}{ll}
\hline Member Function & Description \\
\hline insert (pair) & \begin{tabular}{l} 
Inserts a pair object as an element to the map. If an element with the \\
specified key already exists, the function call does nothing.
\end{tabular} \\
lower_bound (key) & \begin{tabular}{l} 
Returns an iterator pointing to the first element with a key that is \\
equal to or greater than key.
\end{tabular} \\
max_size() & \begin{tabular}{l} 
Returns the theoretical maximum size of the container. \\
Returns a reverse_iterator pointing to the last element in the \\
container.
\end{tabular} \\
rend() & \begin{tabular}{l} 
Returns a reverse_iterator pointing to the first element in the \\
container.
\end{tabular} \\
size() & \begin{tabular}{l} 
Returns the number of elements in the container. \\
The second argument must be a map object of the same type as the
\end{tabular} \\
calling object. The function swaps the contents of the calling object \\
and the second object.
\end{tabular}

Here is an example of how you might define a map container to hold employee ID numbers (as ints) and their corresponding employee names (as strings):
```

map<int, string> employees;

```

This statement defines a map container named employees. Inside the angled brackets <>, the first data type (int) is the type of each key, which in this case are the employee ID numbers. The second data type (string) is the type of the corresponding values, which in this case are the employee names. So, each element of this container will be a key-value pair where the key is an int and the value is a string.

The keys in a map container must be unique. No two elements in a map container can have the same key value.

\section*{Initializing a Map}

You can initialize a map with an initialization list. The following code shows an example:
```

map<int, string> employees =
{{101, "Chris Jones"}, {102, "Jessica Smith"},
{103, "Amanda Stevens"}, (104, "Wi11 Osborn"}};

```

This code creates a map container named employees, and initializes it as follows:
- The first element is \{101, "Chris Jones"\}. In this element, 101 is the key and "Chris Jones" is the value.
- The second element is \{102, "Jessica Smith" \(\}\). In this element, 102 is the key and "Jessica Smith" is the value.
- The third element is \(\{103\), "Amanda Stevens" \(\}\). In this element, 103 is the key and "Amanda Stevens" is the value.
- The fourth element is \(\{104\), "Wi11 Osborn" \(\}\). In this element, 104 is the key and "Will Osborn" is the value.

Notice inside the initialization list:
- The initialization list is enclosed in a set of curly braces \{\}.
- Each element is enclosed in its own set of curly braces, with the key and the value separated by a comma.
- The elements are separated by commas.

As previously mentioned, the keys in a map must be unique. If two or more elements in an initialization list have the same key, only the first will be added to the map. The others will be ignored.

\section*{Adding Elements to an Existing Map}

The map class overloads the [] operator, giving you the ability to add new elements to a map with an assignment statement in the following general format:
```

mapName[key] = value;

```

In the general format, mapName is the name of the map, and key is a key. If key already exists in the map, its associated value will be changed to value. If the key does not exist, it will be added to the map, along with value as its associated value. The following code shows an example:
```

map<int, string> employees;
employees[110] = "Beth Young";
employees[111] = "Jake Brown";
employees[112] = "Emily Davis";

```

The first statement creates an empty map container named employees. The statements that follow then add the following elements to the map:
- \(\mathrm{Key}=110\), Value \(=\) "Beth Young"
- Key \(=111\), Value = "Jake Brown"
- Key \(=112\), Value \(=\) "Emily Davis"

Remember, the keys in a map must be unique. If you assign a new value to an existing key, the new value will replace the previously stored value. For example, look at the following code:
```

map<int, string> employees;
employees[110] = "Beth Young";
employees[110] = "Jake Brown";

```

The first statement creates an empty map container named employees. The second statement adds an element with the key 110 and the value "Beth Young". The third statement assigns the value "Jake Brown" to the element with the key 110.

\section*{Adding Elements with the insert () Member Function}

When an element is stored in a map, it is stored as object of the pair type. The pair type is a struct that has two member variables: first and second. The element's key is stored in the first member variable, and the element's value is stored in the second member variable.

The map class provides an insert () member function that adds a pair object as an element to the map. You can use the STL function make_pair to construct a pair object, as shown in the following code:
```

map<int, string> employees;
employees.insert(make_pair(110, "Beth Young"));
employees.insert(make_pair(111, "Jake Brown"));
employees.insert(make_pair(112, "Emily Davis"));

```

The first statement creates an empty map container named employees. The statements that follow then add the following elements to the map:
- Key \(=110\), Value \(=\) "Beth Young"
- Key \(=111\), Value = "Jake Brown"
- Key \(=112\), Value \(=\) "Emily Davis"

If the element that you are inserting with the insert () member function has the same key as an existing element, the function will not insert the new element.

NOTE: The pair struct and the make_pair function template are declared in the <utility> header file. If you have included the <map> header file, the <utility> header file will be automatically included as well.

\section*{Adding Elements with the emp1ace () Member Function}

The map class provides an emplace() member function that constructs a new element in the container. You simply call the member function, passing the new element's key and value as arguments. The following code shows an example:
```

map<int, string> employees;
employees.emplace(110, "Beth Young");
employees.emplace(111, "Jake Brown");
employees.emplace(112, "Emily Davis");

```

The first statement creates an empty map container named employees. The statements that follow then add the following elements to the map:
- \(\mathrm{Key}=110\), Value \(=\) "Beth Young"
- Key \(=111\), Value = "Jake Brown"
- \(\mathrm{Key}=112\), Value \(=\) "Emily Davis"

If the element that you are inserting with the emplace () member function has the same key as an existing element, the function will not insert the new element.

\section*{Retrieving Values from a Map}

To retrieve a value from a map, you call the at () member function, passing the key that is associated with the desired value. If the specified key exists in the container, the function returns its associated value. If the key does not exist, the function throws an exception. The following code shows an example:
```

// Create a map containing employee IDs and names.
map<int, string> employees =
{{101, "Chris Jones"}, {102, "Jessica Smith"},
{103, "Amanda Stevens"}, (104, "Wil1 Osborn"}};
// Retrieve a value from the map.
cout << employees.at(103) << endl;

```

This code retrieves and displays the value that is associated with the key 103 from the map. The code will display the string "Amanda Stevens".
If the key you pass to the at () member function does not exist in the map, the at () member function will throw an exception. To prevent this, you should first call the count () member function to determine whether the key exists in the map. You call the count () member function, passing a key as the argument. If the specified key exists in the container, the function returns 1 . If the key does not exist, the function returns 0 . The following code shows an example:
```

// Create a map containing employee IDs and names.
map<int, string> employees =
{{101, "Chris Jones"}, {102, "Jessica Smith"},
{103, "Amanda Stevens"}, (104, "Wil1 Osborn"}};
// Retrieve a value from the map.
if (employees.count(103))
cout << employees.at(103) << endl;
else
cout << "Employee not found.\n";

```

\section*{Deleting Elements}

You can delete, or erase, an element from a map using the erase () member function. You call the erase() member function, passing the key that is associated with the element you want to erase. The following code shows an example:
```

// Create a map containing employee IDs and names.
map<int, string> employees =
{{101, "Chris Jones"}, {102, "Jessica Smith"},
{103, "Amanda Stevens"}, (104, "Wi11 Osborn"}};
// Delete the employee with the ID 102.
employees.erase(102);

```

This code creates a map container with four elements. Then, it deletes the element with the key 102 (and the value "Jessica Smith"). The map then contains only three elements.

The erase() member function returns 1 if the specified element was successfully erased, or 0 if it was not found.

\section*{Iterating Over a Map with the Range-Based for Loop}

The range-based for loop is a convenient way to iterate over all of the elements in a map. The following code shows an example of how to display all of the elements in a map:
```

// Create a map containing employee IDs and names.
map<int, string> employees =
{{101, "Chris Jones"}, {102, "Jessica Smith"},
{103, "Amanda Stevens"}, (104, "Wi11 Osborn"}};
// Display each element.
for (auto element : employees)
{
cout << "ID:" << element.first << "\tName:" << element.second << endl;
}

```

Notice we used the auto key word in the declaration of the range variable, element. The auto key word tells the compiler to determine the variable's data type from the context in which it is being used. If we had written the actual data type of the element variable, the loop would have looked like this:
```

for (pair<int, string> element : employees)
{
cout << "ID: " <<element.first << "\tName:" <<element.second << endl;
}

```

As previously mentioned, elements are stored in a map container as objects of the pair type. The pair type is a struct that has two member variables: first and second. The element's key is stored in the first member variable, and the element's value is stored in the second member variable.

\section*{Using an Iterator with a Map}

You can use a bidirectional iterator to access the elements of a map. The map class has a begin() member function that returns an iterator pointing to the first element in the map, and an end () member function that returns an iterator pointing to the end of the map (the position after the last element). Program 17-11 shows an example of using an iterator to display all of the elements of a map.

\section*{Program 17-11}
```

// This program demonstrates an iterator with a map.
\#include <iostream>
\#include <string>
\#include <map>
using namespace std;
int main()
{
// Create a map containing employee IDs and names.
map<int, string> employees =
{ {101,"Chris Jones"}, {102,"Jessica Smith"},
{103,"Amanda Stevens"},{104,"Wi11 Osborn"} };

```
```

    // Create an iterator.
    map<int, string>::iterator iter;
    // Use the iterator to display each element in the map.
    for (iter = employees.begin(); iter != employees.end(); iter++)
    {
        cout << "ID: " << iter->first
                << "\tName: " << iter->second << endl;
    }
    return 0;
    }

```

\section*{Program Output}

ID: 101 Name: Chris Jones
ID: 102 Name: Jessica Smith
ID: 103 Name: Amanda Stevens
ID: 104 Name: Wil1 Osborn

Let's take a closer look at Program 17-11:
- Lines 10 through 12 define a map container named employees, and initialize it with four elements. Notice the map's type is map<int, string>.
- Line 15 defines an iterator that will work with an object of the type map<int, string>. The iterator's name is iter.
- The for loop that appears in lines 18 through 22 uses the iterator to step through the map container.
- The loop's initialization expression iter = employees.begin() causes the iterator to point to the first element in the map.
- The test expression iter != employees.end() causes the loop to execute as long as the iterator does not point to the end of the map.
- The update expression increments the iterator, moving it to the next element in the map.
- The body of the loop, in lines 20 and 21, displays the contents of the element to which the iterator is currently pointing. Remember, each element of the map is a pair object, with the key stored in the first member, and the value stored in the second member.

NOTE: When you access the elements of a map from first to last, you access them in order of their keys.

NOTE: The end() member function returns an iterator pointing to the end of the map, but it does not point to an actual element. It points to the position where an additional element would exist, if it appeared after the last element.

The map class also has a find () member function that searches for an element with a specified key. If the element is found, the find () function returns an iterator to it. If the element is not found, the find() function returns an iterator to the end of the map. The following code shows an example:
```

// Create a map containing employee IDs and names.
map<int, string> employees =
{{101, "Chris Jones"}, {102, "Jessica Smith"},
{103, "Amanda Stevens"}, (104, "Will Osborn"}};
// Create an iterator.
map<int, string>::iterator iter;
// Find employee 103.
iter = employees.find(103);
// Display the employee data.
if (iter != employees.end())
{
cout << "ID: " << iter->first
<< "\tName: " << iter->second << endl;
}
else
{
cout << "Employee not found.\n";
}

```

\section*{Storing vectors as Values in a map}

In Program 17-12, we define a map in which the keys are student names (as strings), and the values are vectors containing test scores.

\section*{Program 17-12}
```

\#include <iostream>
\#include <string>
\#include <vector>
\#include <map>
using namespace std;
int main()
{
// Create vectors to hold test scores.
vector<int> student1Scores = {88, 92, 100};
vector<int> student2Scores = {95, 74, 81};
vector<int> student3Scores = {72, 88, 91};
vector<int> student4Scores = {70, 75, 78};
// Create a map to hold all the test scores.
map<string, vector<int>> testScores;
testScores["Kayla"] = student1Scores;
testScores["Luis"] = student2Scores;
testScores["Sophie"] = student3Scores;
testScores["Ethan"] = student4Scores;

```
```

22 // Display each student's test scores.
23 for (auto element : testScores)
24
25
26
27
28
29
30
31
32
33
34
return 0;
}

```

\section*{Program Output}

Student: Ethan
70
75
78
Student: Kayla
88
92
100
Student: Luis
95
74
81
Student: Sophie
72
88
91
Let's take a closer look at Program 17-12:
- Lines 10 through 13 create four vectors, each holding a different student's test scores.
- Line 16 defines a map container named testScores. Notice the map's type is map<string, vector<int>>. This indicates the keys will be of the string type, and the values will be of the vector<int> type.
- Lines 17 through 20 add the following elements to the map:

Key = "Kayla", Value \(=\) student1Scores, which is a vector<int> object
Key = "Luis", Value = student2Scores, which is a vector<int> object
Key \(=\) "Sophie", Value \(=\) student3Scores, which is a vector<int> object
Key \(=\) "Ethan", Value \(=\) student4Scores, which is a vector<int> object
- The range-based for loop that begins in line 23 iterates over each element in the map. Remember that the range variable, element, is an object of the pair data type. The element object's first member variable is the element's key, and its second member variable is the element's value. So, the expression element.first is a string, and the expression element. second is a vector<int> object. In line 31, the expression element. second[i] is an element in the vector.

Program 17-12 illustrates the process of storing vectors as values in a map, but the program can be simplified in two ways: (1) When we define the map, we can use an initialization list that also creates the vector objects. That will allow us to eliminate the vector definition statements in lines 10 through 13. (2) We can rewrite the inner for loop in lines 29 through 32 as a range-based for loop. Program 17-13 shows the program with these changes.

\section*{Program 17-13}
```

\#include <iostream>
\#include <string>
\#include <vector>
\#include <map>
using namespace std;
int main()
{
// Create vectors to hold test scores.
map<string, vector<int>> testScores =
{ {"Kayla", vector<int> {88, 92, 100 }},
{"Luis", vector<int> {95, 74, 81 }},
{"Sophie", vector<int> {72, 88, 91 }},
{"Ethan", vector<int> {70, 75, 78 }} };
// Display each student's test scores.
for (auto element : testScores)
{
// Display the student name.
cout << "Student: " << element.first << endl;
// Display the student's test scores.
for (auto score : element.second)
{
cout << "\t" << score << endl;
}
}
return 0;
}

```

\section*{Storing Objects of Your Own Classes as Values in a map}

In the examples previously shown, we stored strings, primitive values, and vectors in maps. It is often useful to store objects of classes that you have written in a map. For example, suppose you are writing a program to keep a contact list, and you want to search for a person's contact information by entering that person's name. You could create a map that contains an element for each person in the contact list. In each element, the key is a person's name, and the value is an object containing that person's contact data. You can search the map, using a person's name as the key, and retrieve the object containing that person's contact data.

If you want to store an object as a value in a map, there is one requirement for that object's class: It must have a default constructor. For example, the Contact class shown here holds a person's name and e-mail address. Because it has a default constructor (in lines 12 through 14), objects of this class can be stored as values in a map.

\section*{Contents of Contact. h}
```

\#ifndef CONTACT_H
\#define CONTACT_H
\#include <string>
using namespace std;
class Contact
{
private:
string name;
string email;
public:
Contact()
{ name = "";
email = ""; }
Contact(string n, string em)
{ name = n;
emai1 = em; }
void setName(string n)
{ name = n; }
void setEmail(string em)
{ email = em; }
string getName() const
{ return name; }
string getEmail() const
{ return email; }
};
\#endif

```

Program 17-14 demonstrates how to store objects of the Contact class in a map. The program creates three Contact objects, then stores them in a map, using each Contact object's name field as the key. The user is prompted to enter a name to search for.

\section*{Program 17-14}
```

\#include <iostream>
\#include <string>
\#include <map>
\#include "Contact.h"
using namespace std;
int main()
{
string searchName; // The name to search for
// Create some Contact objects
Contact contact1("Ash1ey Mil1er", "amil1er@faber.edu");
Contact contact2("Jacob Brown", "jbrown@gotham.edu");
Contact contact3("Emily Ramirez", "eramirez@coolidge.edu");
// Create a map to hold the Contact objects.
map<string, Contact> contacts;
// Create an iterator for the map.
map<string, Contact>::iterator iter;
// Add the contact objects to the map.
contacts[contact1.getName()] = contact1;
contacts[contact2.getName()] = contact2;
contacts[contact3.getName()] = contact3;
// Get the name to search for.
cout << "Enter a name: ";
get1ine(cin, searchName);
// Search for the name.
iter = contacts.find(searchName);
// Display the results.
if (iter != contacts.end())
{
cout << "Name: " << iter->second.getName() << endl;
cout << "Email: " << iter->second.getEmail() << endl;
}
else
{
cout << "Contact not found.\n";
}
return 0;
}

```

\section*{Program Output (with Example Input Shown in Bold)}

Enter a name: Emily Ramirez Enter
Name: Emily Ramirez
Emai1: eramirez@coolidge.edu

\section*{Program Output (with Example Input Shown in Bold)}

Enter a name: Billy Clark Enter
Contact not found.

Let's take a closer look at Program 17-14:
- Lines 12 through 14 create three Contact objects named contact1, contact2, and contact3.
- Line 17 defines a map named contacts. Inside the angled brackets <>, the first data type (string) is the type of each key. The second data type (Contact) is the type of the corresponding values. So, each element of this container will be a key-value pair where the key is a string and the value is a Contact object.
- Line 20 defines an iterator that can be used with the contacts map.
- Line 23 adds an element to the contacts map. The key is the string "Ashley Miller", and the value is the contact1 object.
- Line 24 adds another element to the contacts map. The key is the string "Jacob Brown", and the value is the contact2 object.
- Line 25 adds another element to the contacts map. The key is the string "Emily Ramirez", and the value is the contact 3 object.
- Lines 28 and 29 prompt the user to enter a name to search for. The user's input is stored in searchName.
- Line 32 calls the contacts. find() member function to search for the name that was entered by the user. If the name is found as a key in the map, the member function returns an iterator to the element. If the name is not found, the member function returns an iterator to the end of the map.
- If the name was found, the statements in lines 37 and 38 display the name and e-mail address for the contact. Remember, the iterator is pointing to a pair object. The pair object's first member variable is the element's key, and the pair object's second member variable is the element's value. So, in lines 37 and 38 , the expression iter->second references a Contact object. The expression iter->second.getName() returns that object's name field, and the expression iter->second.getEmail () returns that object's email field.

Program 17-15 shows another example in which we use a range-based for loop to iterate over a map containing Contact objects as values.

\section*{Program 17-15}
```

\#include <iostream>
\#include <string>
\#include <map>
\#include "Contact.h"
using namespace std;

```
```

Program 17-15 (continued)
int main()
{
// Create some Contact objects
Contact contact1("Ash1ey Miller", "amiller@faber.edu");
Contact contact2("Jacob Brown", "jbrown@gotham.edu");
Contact contact3("Emily Ramirez", "eramirez@coolidge.edu");
// Create a map to hold the Contact objects.
map<string, Contact> contacts;
// Add the contact objects to the map.
contacts[contact1.getName()] = contact1;
contacts[contact2.getName()] = contact2;
contacts[contact3.getName()] = contact3;
// Display all objects in the map.
for (auto element : contacts)
{
cout << element.second.getName() << "\t"
<< element.second.getEmail() << endl;
}
return 0;
}

```

\section*{Program Output}

Ashley Miller amiller@faber.edu
Emily Ramirez eramirez@coolidge.edu
Jacob Brown jbrownegotham.edu
In lines 25 and 26, the range variable element is a pair object. The pair object's first member variable is the element's key, and the pair object's second member variable is the element's value. So, the expression element. second references a Contact object. The expression element. second.getName() returns that object's name field, and the expression element. second.getEmail() returns that object's email field.
Program 17-15 illustrates the process of using your own objects as values in a map, but the program can be simplified. When we define the map, we can use an initialization list that also creates the Contact objects. That will allow us to eliminate the Contact definition statements in lines 10 through 12. Program 17-16 shows the program with these changes.

\section*{Program 17-16}
```

\#include <iostream>
\#include <string>
\#include <map>
\#include "Contact.h"
using namespace std;

```
6
```

int main()
{
// Create a map holding the Contact objects.
map<string, Contact> contacts =
{{ "Ashley Miller", Contact("Ash1ey Miller", "amiller@faber.edu") },
{ "Jacob Brown", Contact("Jacob Brown", "jbrown@gotham.edu") },
{ "Emily Ramirez", Contact("Emily Ramirez", "eramirez@coolidge.edu")}
};
// Display all objects in the map.
for (auto element : contacts)
{
cout << element.second.getName() << "\t"
<< element.second.getEmail() << endl;
}
return 0;
}

```

\section*{Program Output}

Ashley Miller amiller@faber.edu
Emily Ramirez eramirez@coolidge.edu
Jacob Brown jbrown@gotham.edu

\section*{Using an Object of Your Own Class as a Key}

You can use objects of a class that you have written as keys in a map, as long as the class has overloaded the < operator. For example, look at the Customer class shown here:

\section*{Contents of Customer.h}
```

\#ifndef CUSTOMER_H
\#define CUSTOMER_H
\#include<string>
using namespace std;
class Customer
{
private:
int custNumber;
string name;
public:
Customer(int cn, string n)
{ custNumber = cn;
name = n; }
void setCustNumber(int cn)
{ custNumber = cn; }
void setName(string n)
{ name = n; }
int getCustNumber() const
{ return custNumber; }

```
```

    string getName() const
    { return name; }
        bool operator < (const Customer &right) const
        { bool status = false;
        if (custNumber < right.custNumber)
        status = true;
    return status; }
    };
\#endif

```

The Customer class holds two pieces of data about a customer: the customer number (custNumber) and the customer's name (name). The overloaded < operator (in lines 28 through 35 ) returns true if the custNumber member is less than the parameter's custNumber member. Otherwise, it returns false.

Suppose we are writing a program that assigns seats in a theater to customers, and we want to use Customer objects as the keys in a map. Program 17-17 shows an example. In line 15 , the program defines a map that uses Customer objects as keys, and strings as values.

\section*{Program 17-17}
```

\#include <iostream>
\#include <string>
\#include <map>
\#include "Customer.h"
using namespace std;
int main()
{
// Create some Customer objects.
Customer customer1(1001, "Sarah Scott");
Customer customer2(1002, "Austin Hil1");
Customer customer3(1003, "Megan Cruz");
// Create a map to hold the seat assignments.
map<Customer, string> assignments;
// Use the map to store the seat assignments.
assignments[customer1] = "1A";
assignments[customer2] = "2B";
assignments[customer3] = "3C";
// Display all objects in the map.
for (auto element : assignments)
{
cout << element.first.getName() << "\t"
<< element.second << endl;
}
return 0;
}

```

\section*{Program Output}
\begin{tabular}{ll} 
Sarah Scott & \(1 A\) \\
Austin Hil1 & \(2 B\) \\
Megan Cruz & \(3 C\)
\end{tabular}

Program 17-17 illustrates the process of using your own objects as keys in a map, but the program can be simplified. When we define the map, we can use an initialization list that also creates the Customer objects. That will allow us to eliminate the Customer definition statements in lines 10 through 12 . Program 17-18 shows the program with these changes.

\section*{Program 17-18}
```

\#include <iostream>
\#include <string>
\#include <map>
\#include "Customer.h"
using namespace std;
int main()
{
// Create a map to hold the seat assignments.
map<Customer, string> assignments =
{ { Customer(1001, "Sarah Scott"), "1A"},
{ Customer(1002, "Austin Hil1"), "2B"},
{ Customer(1003, "Megan Cruz"), "3C" } };
// Display all objects in the map.
for (auto element : assignments)
{
cout << element.first.getName() << "\t"
<< element.second << endl;
}
return 0;
}

```

\section*{Program Output}

Sarah Scott 1A
Austin Hill 2B
Megan Cruz 3C

\section*{The unordered_map Class}

Beginning in C++11, the STL provides a class template named unordered_map that is similar to the map class, except in two regards: (1) the keys in an unordered_map are not sorted in any particular way, and (2) the unordered_map class has better performance. If you will be making a lot of searches on a large number of elements, and you are not concerned with retrieving them in key order, you should probably use the unordered_map class instead of the map class.

To use the unordered_map class, you must write the \#include <unordered_map> directive in your program. The unordered_map class has a similar set of member functions as the map class (many of which are listed in Table 17-10), and in most cases, working with an unordered_map is just like working with a map. The following code shows an unordered_map being initialized with elements, then an element being retrieved and displayed:
```

// Create an unordered_map containing employee IDs and names.
unordered_map<int, string> employees =
{{101, "Chris Jones"}, {102, "Jessica Smith"},
{103, "Amanda Stevens"}, (104, "Wi11 Osborn"}};
// Retrieve a value from the map.
cout << employees.at(103) << endl;

```

The following code shows an example of using a range-based for loop to display all of the elements in a map:
```

// Create an unordered_map containing employee IDs and names.
unordered_map <int, string> employees =
{{101, "Chris Jones"}, {102, "Jessica Smith"},
{103, "Amanda Stevens"}, (104, "Wi11 Osborn"}};
// Display each element.
for (auto element : employees)
{
cout << "ID:" << element.first << "\tName:" << element.second << endl;
}

```

NOTE: The differences between the unordered_map class and the map class are a result of the way each internally stores its elements. The map class uses a data structure known as a binary tree, and the unordered_map class uses a hash table.

\section*{The multimap Class}

The multimap class lets you create a map container in which multiple elements can have the same key. In other words, duplicate keys are allowed in a multimap. To use the multimap class, you will need to write the \#include<map> directive in your program. Table 17-11 lists many (but not all) of the multimap class's member functions.

Table 17-11 Some of the multimap Member Functions
\begin{tabular}{ll}
\hline Member Function & Description \\
\hline begin() & Returns an iterator to the first element in the container. \\
cbegin () & Returns a const_iterator to the first element in the container. \\
cend () & Returns a const_iterator pointing to the end of the container. \\
clear () & Erases all of the elements in the container. \\
count (key) & Returns the number of elements containing the specified key.
\end{tabular}

Table 17-11 (continued)
\begin{tabular}{|c|c|}
\hline Member Function & Description \\
\hline crbegin() & Returns a const_reverse_iterator pointing to the last element in the container. \\
\hline crend () & Returns a const_reverse_iterator pointing to the first element in the container. \\
\hline emplace(key, value) & Inserts a new element containing the specified key and value into the container. \\
\hline empty () & Returns true if the container is empty, or false otherwise. \\
\hline end () & Returns an iterator to the last element in the container. \\
\hline equa1_range(key) & Returns a pair object. The pair object's first member is an iterator pointing to the first element in the multimap that matches the specified key. The pair object's second member is an iterator pointing to the position after the last element that matches the specified key. If the specified key is not found, both iterators will point to the element that would naturally appear after the element that was searched for. \\
\hline erase(key) & Erases all of the elements containing the specified key. The function returns the number of elements that were erased. \\
\hline find(key) & Searches for an element with the specified key, and returns an iterator to the first matching element. If the element is not found, the function returns an iterator to the end of the container. \\
\hline insert(pair) & Inserts a pair object as an element to the map. \\
\hline lower_bound (key) & Returns an iterator pointing to the first element with a key that is equal to or greater than key. \\
\hline max_size() & Returns the theoretical maximum size of the container. \\
\hline rbegin() & Returns a reverse_iterator pointing to the last element in the container. \\
\hline rend() & Returns a reverse_iterator pointing to the first element in the container. \\
\hline size() & Returns the number of elements in the container. \\
\hline swap (second) & The second argument must be a map object of the same type as the calling object. The function swaps the contents of the calling object and the second object. \\
\hline upper_bound (key) & Returns an iterator pointing to the first element with a key that is greater than key. \\
\hline
\end{tabular}

For example, in a phone book application, you could store names and phone numbers in a multimap container, using the names as keys and the phone numbers as values. If a person has multiple phone numbers, you could store multiple elements using that person's name as the key. Figure 17-5 illustrates this concept.

Figure 17-5 Duplicate keys stored in a multimap container

In Figure 17-5, there are two elements with the key "Will", two elements with the key "Faye", and two elements with the key "Sarah". Program 17-19 shows how to define a multimap and initialize it with these elements.

\section*{Program 17-19}
```

\#include <iostream>
\#include <string>
\#include <map>
using namespace std;
int main()
{
// Define a phonebook multimap.
multimap<string, string> phonebook =
{ {"Wil1", "555-1212"}, {"Wi11", "555-0123"},
{"Faye", "555-0707"}, {"Faye", "555-1234"},
{"Sarah", "555-8787"}, {"Sarah", "555-5678"} };
// Display the elements in the multimap.
for (auto element : phonebook)
{
cout << element.first << "\t"
<< element.second << endl;
}
return 0;
}

```

\section*{Program Output}
\begin{tabular}{ll} 
Faye & \(555-0707\) \\
Faye & \(555-1234\) \\
Sarah & \(555-8787\) \\
Sarah & \(555-5678\) \\
Will & \(555-1212\) \\
Will & \(555-0123\)
\end{tabular}

As with the map class, the elements of a multimap are ordered. When you iterate over a multimap, you retrieve its elements in order of their keys. The multimap class also provides many of the same member functions as the map class. There are some differences between the multimap class and the map class, however, and we will focus on many of those differences in the rest of this section.

\section*{Adding Elements to a multimap}

Unlike the map class, the multimap class does not overload the [] operator. So, you cannot write an assignment statement to add a new element to a multimap. Instead, you can use either the emplace() member function, or the insert () member function.

The multimap class's emplace() member function adds a new element to the container. You simply call the member function, passing the new element's key and value as arguments. The following code shows an example:
```

multimap<string, string> phonebook;
phonebook.emplace("Wi11", "555-1212");
phonebook.emplace("Wi11", "555-0123");
phonebook.emplace("Faye", "555-0707");
phonebook.emplace("Faye", "555-1234");
phonebook.emplace("Sarah", "555-8787");
phonebook.emplace("Sarah", "555-5678");

```

The first statement creates an empty mult imap container named phonebook. The statements that follow use the emplace() member function to add the elements shown in Figure 17-5.

If the element that you are inserting with the emplace() member function has the same key as an existing element, the function adds a new element with the same key.

The insert() member function adds a pair object as an element to the multimap. You can use the STL function make_pair to construct a pair object, as shown in the following code:
```

multimap<string, string> phonebook;
phonebook.insert(make_pair("Wi11", "555-1212"));
phonebook.insert(make_pair("Wi11", "555-0123"));
phonebook.insert(make_pair("Faye", "555-0707"));
phonebook.insert(make_pair("Faye", "555-1234"));
phonebook.insert(make_pair("Sarah", "555-8787"));
phonebook.insert(make_pair("Sarah", "555-5678"));

```

The first statement creates an empty mult imap container named phonebook. The statements that follow use the insert () member function to add the elements shown in Figure 17-5.

If the element that you are inserting with the insert () member function has the same key as an existing element, the function adds a new element with the same key.

\section*{Getting the Number of Elements with a Specified Key}

The multimap class's count () member function accepts a key as its argument, and returns the number of elements that match the specified key. Program 17-20 demonstrates.

\section*{Program 17-20}
```

\#include <iostream>
\#include <string>
\#include <map>
using namespace std;
int main()
{
// Define a phonebook multimap.
multimap<string, string> phonebook =
{ {"Wil1", "555-1212"}, {"Wil1", "555-0123"},
{"Faye", "555-0707"}, {"Faye", "555-1234"},
{"Sarah", "555-8787"}, {"Sarah", "555-5678"} };
// Display the number of elements that match "Faye".
cout << "Faye has " << phonebook.count("Faye") << " elements.\n";
return 0;
}

```

\section*{Program Output}

Faye has 2 elements.

\section*{Retrieving the Elements with a Specified Key}

Like the map class, the multimap class has a find() member function that searches for an element with a specified key. If the key is found, the find() function returns an iterator to the first element matching it. If the element is not found, the find() function returns an iterator to the end of the map.

If you want to retrieve all of the elements matching a specified key, use the multimap class's equal_range member function. The equal_range member function returns a pair object. The pair object's first member is an iterator pointing to the first element in the multimap that matches the specified key. The pair object's second member is an iterator pointing to the position after the last element that matches the specified key. Program 17-21 demonstrates how to use the function.

\section*{Program 17-21}
```

\#include <iostream>
\#include <string>
\#include <map>
using namespace std;
int main()
{
// Define a phonebook multimap.
multimap<string, string> phonebook =
{ {"Wil1", "555-1212"}, {"Wil1", "555-0123"},
{"Faye", "555-0707"}, {"Faye", "555-1234"},
{"Sarah", "555-8787"}, {"Sarah", "555-5678"} };

```
```

14
15
16
17
18
19
20
21
22
23
24
25
26
27
28
29
30
31 return 0;
32 }

```

\section*{Program Output}
Faye 555-0707

Faye 555-1234

Let's take a closer look at the program:
- Lines 9 through 12 define a multimap container named phonebook, initialized with six elements.
- Lines 16 and 17 define a pair variable named range. The range variable will receive the object that is returned from the equal_range member function. The object's first and second members will both be iterators for the multimap container.
- Line 20 defines an iterator named iter for the multimap container.
- Line 23 calls the phonebook container's equal_range member function, specifying "Faye" as the key to search for. The equal_range function returns a pair object that is assigned to the range variable.
- The for loop in lines 26 through 29 iterates over all of the elements matching the key "Faye", displaying their values. Here are the details of the loop:
o The iter iterator is initially set to range.first.
o The loop repeats as long as iter is not equal to range. second.
o At the end of each loop iteration, iter is incremented to the next element.
o Each time the loop iterates, it displays the contents of the element to which iter is pointing (line 26).

NOTE: When searching for a range of elements with the equal_range member function, if the specified key is not found, both iterators will point to the element that would naturally appear after the element that was searched for.

\section*{Deleting Elements from a multimap}

You can delete, or erase, elements from a multiap using the erase() member function. You call the erase () member function, passing the key that is associated with the elements that you want to erase. All of the elements matching the specified key will be erased from the multimap. The erase() member function returns the number of elements that were erased. The following code shows an example:
```

// Define a phonebook multimap.
multimap<string, string> phonebook =
{ {"Wi11", "555-1212"}, {"Wi11", "555-0123"},
{"Faye", "555-0707"}, {"Faye", "555-1234"},
{"Sarah", "555-8787"}, {"Sarah", "555-5678"} };
// Delete Will's phone numbers from the multimap.
phonebook.erase("Wi11");

```

This code creates a multimap container with six elements. Then, it deletes all of the elements with the key "Will". (Two elements will be deleted.) The multimap then contains only four elements.

\section*{The unordered_multimap Class}

Beginning in C++11, the STL provides a class template named unordered_multimap that is similar to the multimap class, except in two regards: (1) the keys in an unordered_ multimap are not sorted in any particular order, and (2) the unordered_multimap class has better performance. If you will be making a lot of searches on a large number of elements, and you are not concerned with retrieving them in key order, you should probably use the unordered_multimap class instead of the multimap class.

To use the unordered_multimap class, you must write the \#include <unordered_ multimap> directive in your program. The unordered_multimap class has a similar set of member functions as the multimap class, and in most cases, working with an unordered_multimap is just like working with a multimap.

NOTE: The differences between the unordered_multimap class and the multimap class are a result of the way each internally stores its elements. The multimap class uses a data structure known as a binary tree, and the unordered_multimap class uses a hash table.

\section*{Checkpoint}
17.20 Each element that is stored in a map has two parts. What are they?
17.21 Write a statement that defines a map named myMap. The keys in myMap should be ints, and the values should be strings.
17.22 Suppose an empty map named employee has been created. What does the following statement do?
employee[543] = "Joanne Manchester";
17.23 Describe two ways in which you can retrieve an element with a particular key in a map.
17.24 If you want to store objects of a class you have written, as values in a map, what do you have to make sure that the class has?
17.25 If you want to store objects of a class you have written, as keys in a map, what do you have to make sure that the class has?
17.26 What is the difference between a map and an unordered_map?
17.27 What is the difference between a map and an multimap?

\subsection*{17.5 The set, multiset, and unordered_set Classes}

CONCEPT: A set contains a collection of unique values.
A set is an associative container that stores a collection of unique values in a way that is similar to a mathematical set. You use the STL class template set to implement a set container in C++. Here are two important things to know about the STL set container:
- All the elements in a set must be unique. No two elements can have the same value.
- The elements in a set are automatically sorted in ascending order.

To use the set class, you will need to \#include the <set> header file in your program. Then, you can define a set object using one of the set class constructors. Table 17-12 shows the general format of a set definition statement using each constructor. Table 17-13 lists many (but not all) of the set class's member functions.

Table 17-12 set Definition Statements
\begin{tabular}{ll} 
Default Constructor & \begin{tabular}{l} 
set<dataType> name; \\
Creates an empty set object. In the general format, dataType is the \\
data type of each element, and name is the name of the set.
\end{tabular} \\
Ret<dataType> name (iterator1, iterator2) ; \\
Censtructor \\
Creates a set object that initially contains a range of values speci- \\
fied by two iterators. In the general format, dataType is the data \\
type of each element, and name is the name of the set. The \\
iterator1 and iterator2 arguments mark the beginning and \\
end of a range of values that will be stored in the set. (iterator2 \\
marks the end of the range, but the element pointed to by \\
iterator2 will not be included in the range.) Any duplicate \\
values in the range will be added only once to the set.
\end{tabular}

Table 17-13 Some of the set Member Functions
\begin{tabular}{|c|c|}
\hline Member Function & Description \\
\hline begin() & Returns an iterator to the first element in the container. \\
\hline cbegin() & Returns a const_iterator to the first element in the container. \\
\hline cend () & Returns a const_iterator pointing to the end of the container. \\
\hline clear () & Erases all of the elements in the container. \\
\hline count (value) & Returns the number of elements containing the specified value. (For the set class, the count () function returns either 0 or 1 . For the multiset class, the function can return values greater than 1.) \\
\hline crbegin() & Returns a const_reverse_iterator pointing to the last element in the container. \\
\hline crend () & Returns a const_reverse_iterator pointing to the first element in the container. \\
\hline emplace(args...) & Constructs a new element into the container, passing the list of arguments to the element's constructor. If an element with the specified value already exists, the function call does nothing. \\
\hline empty () & Returns true if the container is empty, or false otherwise. \\
\hline end () & Returns an iterator to the end of the container (the position after the last element). \\
\hline equa1_range(value) & Returns a pair object. The pair object's first member is an iterator pointing to the first element in the set that matches the specified value. The pair object's second member is an iterator pointing to the position after the last element that matches the specified value. If the specified value is not found, both iterators will point to the element that would naturally appear after the element that was searched for. (With the set class, the range will have at most one element. With the multiset class, the range can have multiple elements.) \\
\hline erase(value) & Erases the element containing the specified value. The function returns 1 if the element was erased, or 0 if no matching element was found. \\
\hline find(value) & Searches for an element with the specified value. If the element is found, the function returns an iterator to it. If the element is not found, the function returns an iterator to the end of the set. \\
\hline insert(value) & Inserts a value as an element to the set. If an element with the specified value already exists, the function does not insert a new element. The function returns a pair object, with its first member being an iterator pointing to the newly inserted element (or the equivalent element, if it was already present), and with the second member being the bool value true if a new element was inserted, or false if the element was already present. \\
\hline lower_bound(value) & Returns an iterator pointing to the first element with a key that is equal to or greater than value. \\
\hline max_size() & Returns the theoretical maximum size of the container. \\
\hline rbegin() & Returns a reverse_iterator pointing to the last element in the container. \\
\hline rend() & Returns a reverse_iterator pointing to the first element in the container. \\
\hline size() & Returns the number of elements in the container. \\
\hline swap (second) & The second argument must be a map object of the same type as the calling object. The function swaps the contents of the calling object and the second object. \\
\hline upper_bound(value) & Returns an iterator pointing to the first element with a key that is greater than value. \\
\hline
\end{tabular}

Here is an example of how you might define a set container to hold integers:
```

set<int> numbers;

```

This statement defines a set container named numbers. Inside the angled brackets <>, the data type int is the type of each element. You can provide an initialization list to initialize the set, as shown here:
```

set<int> numbers = {1, 2, 3, 4, 5};

```

Here is an example of defining a set to hold strings:
```

set<string> names = {"Joe", "Karen", "Lisa", "Jackie"};

```

A set cannot contain duplicate items, so, if the same value appears more than once in an initialization list, it will be added to the set only one time. For example, the following set will contain the values \(1,2,3,4\), and 5 :
```

set<int> numbers = {1, 1, 2, 3, 3, 3, 4, 5, 5};

```

\section*{Adding Elements to an Existing set}

The set class provides an insert () member function that adds a new element to the container. You simply call the member function, passing the new element's value as an argument. The following code shows an example:
```

set<int> numbers;
numbers.insert(10);
numbers.insert(20);
numbers.insert(30);

```

The first statement creates an empty set container named numbers. The statements that follow add the values 10,20 , and 30 to the set. If the value that you are inserting already exists in the set, the insert()member function will do nothing (no new element will be inserted).

NOTE: The set class also provides the emplace() member function, for inserting elements. You will see an example of it momentarily. For a review of the difference between the emplace() and insert() member functions, see the discussion on emplacement that appears in this chapter's section on vectors.

\section*{Iterating Over a set with the Range-Based for Loop}

The range-based for loop is a convenient way to iterate over all of the elements in a set. The following code shows an example of how to display all of the elements in a set:
```

// Create a set containing names.
set<string> names = {"Joe", "Karen", "Lisa", "Jackie"};
// Display each element.
for (string element : names)
{
cout << element << endl;
}

```

\section*{Using an Iterator with a set}

You can use a bidirectional iterator to access the elements of a set. The set class provides the begin() and cbegin() member functions that return an iterator pointing to the first element in the set, and the end () and cend () member functions that return an iterator pointing to the end of the set (the position after the last element). The following code shows an example of using an iterator to display all of the elements of a set:
```

// Create a set containing names.
set<string> names = {"Joe", "Karen", "Lisa", "Jackie"};
// Create an iterator.
set<string>::iterator iter;
// Use the iterator to display each element in the set.
for (iter = names.begin(); iter != names.end(); iter++)
{
cout << *iter << endl;
}

```

NOTE: The end() and cend()member functions return an iterator pointing to the end of the set, but it does not point to an actual element. It points to the position where an additional element would exist, if it appeared after the last element.

\section*{Determining Whether a Value Exists in a set}

You can use either the count () member function or the find() member function to determine whether a value exists in a set. The count () member function accepts the desired value as an argument, and returns 1 if the value is found in the set, or 0 if the value is not found. Here is an example:
```

set<string> names = {"Joe", "Karen", "Lisa", "Jackie"};
if (names.count("Lisa"))
cout << "Lisa was found in the set.\n";
else
cout << "Lisa was not found.\n";

```

The find() member function accepts the desired value as an argument, and returns an iterator that points to the element if it is found in the set. If the element is not found, the find() function returns an iterator to the end of the set. The following code shows an example:
```

// Create a set containing names.
set<string> names = {"Joe", "Karen", "Lisa", "Jackie"};
// Create an iterator.
set<string>::iterator iter;
// Find "Karen".
iter = names.find("Karen");
// Display the result.
if (iter != names.end())

```
```

{
cout << *iter << " was found.\n";
}
else
{
cout << "Karen was not found.\n";
}

```

\section*{Storing Objects of Your Own Classes in a set}

You can store objects of a class that you have written in a set, as long as the class has overloaded the < operator. The set class uses the < operator to determine the order in which to store elements, and to detect duplicates. (Suppose we are comparing two values: value1 and value2. If value1 is NOT less than value2, and value2 is NOT less than value1, then the two values are equal. This is the logic that the set class uses to determine whether two values are duplicates.)
For example, recall the Customer class shown earlier in this chapter, in our discussion of the map class. (See the contents of the Customer.h file.) The Customer class holds two pieces of data about a customer: the customer number and the customer's name. The class also has an overloaded < operator that compares customer numbers. If we store objects of the Customer class in a set container, the objects will be sorted by customer number, and the container will not allow objects with the same customer number to be stored. Program 17-22 demonstrates this.

\section*{Program 17-22}
```

\#include <iostream>
\#include <set>
\#include "Customer.h"
using namespace std;
int main()
{
// Create a set of Customer objects.
set<Customer> customerset =
{ Customer(1003, "Megan Cruz"),
Customer(1002, "Austin Hil1"),
Customer(1001, "Sarah Scott")
};
// Try to insert a duplicate customer number.
customerset.emplace(1001, "Evan Smith");
// Display the set elements
cout << "List of customers:\n";
for (auto element : customerset)
{
cout << element.getCustNumber() << " "
<< element.getName() << endl;
}

```
```

Program 17-22 (continued)
// Search for customer number 1002.
cout << "\nSearching for Customer Number 1002:\n";
auto it = customerset.find(Customer(1002, ""));
if (it != customerset.end())
cout << "Found: " << it->getName() << endl;
else
cout << "Not found.\n";
return 0;
}

```

\section*{Program Output}

List of customers:
1001 Sarah Scott
1002 Austin Hill
1003 Megan Cruz
Searching for Customer Number 1002:
Found: Austin Hill

Let's take a closer look at the program:
- Lines 9 through 13 define a set container named customerset. The container is initialized with three Customer objects.
- Line 16 calls the emplace() member function to add a Customer object to the set. However, the customer number that is being passed to the emplace() function is already in the set. As a result, the object will not be added to the set.
- The loop in lines 20 through 24 displays all of the set container's elements. Notice in the program output, the elements are retrieved in order of their customer numbers.
- Next, the program searches the set container for an object with the customer number 1002. The statement in line 28 defines an iterator, assigning it the value returned from the find () member function.

Look carefully at the argument we are passing to the find() member function. The expression Customer (1002, " " ) constructs a temporary, nameless Customer object that has 1002 as the customer number, and " " as the customer name. (Because we are simply using this object to search for an element with customer number 1002, there is no need to provide a meaningful value for the customer name.) The find() member function will accept this Customer object as an argument, and it will search the container for an element that has a matching customer number. (Remember, the set container uses the Customer class's overloaded < operator to determine whether two objects are equal.) If a matching element is found, the function returns an iterator pointing to it. Otherwise, it returns an iterator pointing to the end of the container.
- The if/else statement in lines 30 through 33 tests the iterator to determine whether it is pointing to a matching element, or the end of the container, and displays a message indicating the results of the search.

\section*{The multiset Class}

The multiset class lets you create a set container that can store duplicate elements. To use the multiset class, you will need to \#include the <set> header file in your program. The class provides the same member functions as the set class, with these two differences:
- In the set class, the count () member function returns either 0 or 1 . In the multiset class, the count () member function can return values greater than 1.
- In the set class, the equal_range() member function returns a range with, at most, one element. In the multiset class, the equal_range() member function can return a range with multiple elements.

\section*{The unordered_set and unordered_multiset Classes}

Beginning in C++11, the STL provides class templates named unordered_set and unordered_multiset. These are similar to the set and multiset classes, except in two regards: (1) the values stored in an unordered_set or an unordered_multiset are not sorted in any particular way, and (2) the unordered_set and unordered_multiset classes has better performance than the set and multiset classes. If you will be making a lot of searches on a large number of elements, and you are not concerned with retrieving them in any order, you should probably use the unordered_set or unordered_multiset classes instead of set or multiset.

To use the unordered_set or unordered_multiset classes, you must write the \#include <unordered_set> directive in your program. In most cases, working with an unordered_set or unordered_multiset is similar to working with a set or multiset.

\section*{Checkpoint}
17.28 What are two differences between a set and a vector?
17.29 Write a statement that defines an empty set object named aset, that can hold strings.
17.30 Write a statement that defines a set object named aset, that can hold ints. The set should be initialized with these values: \(10,20,30,40\)
17.31 What happens when you use the insert () member function to insert a value into a set, and that value is already in the set?
17.32 What value does the set class's count member function return?
17.33 If you store objects of a class that you have written in a set, what must the class overload?
17.34 What is the difference between a set and a multiset?
17.35 In what two ways are the unordered_set and unordered_multiset different from the set and multiset classes?

\subsection*{17.6 Algorithms \\ CONCEPT: Many commonly used algorithms are written as function templates in the STL.}

The STL provides a number of algorithms, implemented as function templates, in the <algorithm> header file. These functions perform various operations on ranges of elements. A range of elements is a sequence of elements denoted by two iterators. The first iterator points to the first element in the range, and the second iterator points to the end of the range (the element to which the second iterator points is not included in the range). The algorithms can be organized in the following categories:
- Min/max algorithms:

Determine the smallest (min) and largest (max) values in a range of elements
- Sorting algorithms:

Sort a range of elements, or determine whether a range is sorted
- Search algorithms:

Perform various searching operations on a sorted range of elements
- Read-only sequence algorithms:

Iterate over a range of elements, performing various operations that do not modify the elements
- Copying and moving algorithms:

Use various techniques to copy or move ranges of elements.
- Swapping algorithms:

Swap values, ranges of elements, or the values pointed to by iterators
- Replacement algorithms:

Replace elements of a specified value
- Removal algorithms:

Remove elements
- Reversal algorithms:

Reverse the order of elements in a range
- Fill algorithms:

Fill the elements in a range with values
- Rotation algorithms:

Rotate the elements in a range with values
- Shuffling algorithms:

Shuffle the elements in a range
- Set algorithms:

Perform common mathematical set operations on a range of elements
- Transformation algorithm:

Iterate over ranges of elements, performing an operation using each element
- Partition algorithms:

Partition a range of elements into two groups
- Merge algorithms:

Merge ranges of elements

\section*{- Permutation algorithms:}

Rearrange a range of elements into all of its different possible permutations
- Heap algorithms:

Create and work with a heap data structure
- Lexicographical comparison algorithm:

Makes a lexicographical comparison between two ranges of elements
At the time this was written, there are 85 function templates in the <al gorithm> header file. For a summary of all of the STL algorithms, see Appendix H on the Computer Science Portal at www.pearsonglobaleditions.com/gaddis. We will not discuss all of the STL algorithms in this chapter, but we will look at examples of some of the more interesting ones.

\section*{Sorting and Searching Algorithms}

The <algorithm> header file defines several function templates for sorting and searching. We will look at two of them: sort () and binary_search(). The sort function takes the following general format:
```

sort(iterator1, iterator2)

```

In the general format, iterator1 and iterator2 mark the beginning and end of a range of elements. The function sorts the range of elements in ascending order. The binary_ search () function takes the following general format:
```

binary_search(iterator1, iterator2, value)

```

In the general format, the iterator1 and iterator2 arguments mark the beginning and end of a range of elements that are sorted in ascending order, and value is the value to search for. The function returns true if the value is found in the range of elements, or false otherwise. Program 17-23 demonstrates both the sort() and binary_search()functions.

\section*{Program 17-23}
```

\#include <iostream>
\#include <vector>
\#include <algorithm>
using namespace std;
int main()
{
int searchValue; // Value to search for
// Create a vector of unsorted integers.
vector<int> numbers = {10, 1, 9, 2, 8, 3, 7, 4, 6, 5};
// Sort the vector.
sort(numbers.begin(), numbers.end());

```
```

Program 17-23 (continued)
// Display the vector.
cout << "Here are the sorted values:\n";
for (auto element : numbers)
cout << element << " ";
cout << endl;
// Get the value to search for.
cout << "Enter a value to search for: ";
cin >> searchValue;
// Search for the value.
if (binary_search(numbers.begin(), numbers.end(), searchValue))
cout << "That value is in the vector.\n";
else
cout << "That value is not in the vector.\n";
return 0;
}

```

\section*{Program Output}

Here are the sorted values:
12345678910
Enter a value to search for: 8
That value is in the vector.

\section*{Program Output}

Here are the sorted values:
123445678910
Enter a value to search for: 99
That value is not in the vector.

The sort () and binary_search () functions use the < operator to compare elements. If the elements that you are sorting and searching contain your own class objects, be sure to overload the < operator. For example, recall the Customer class shown earlier in this chapter, in our discussion of the map class. (See the contents of the Customer.h file.) The Customer class holds two pieces of data about a customer: the customer number and the customer's name. The class also has an overloaded < operator that compares customer numbers. If we store objects of the Customer class in a sequence container, we can use the STL sort () and binary_search() functions to sort and search the container for an object containing a particular customer number. Program 17-24 demonstrates this.

\section*{Program 17-24}
```

\#include <iostream>
\#include <vector>
\#include <algorithm>
\#include "Customer.h"
using namespace std;

```
```

int main()
{
int searchValue; // Value to search for
// Create a vector of unsorted Customer objects.
vector<Customer> customers =
{ Customer(1003, "Megan Cruz"),
Customer(1001, "Sarah Scott"),
Customer(1002, "Austin Hil1")
};
// Sort the vector.
sort(customers.begin(), customers.end());
// Display the vector.
cout << "Here are the sorted customers:\n";
for (auto element : customers)
{
cout << element.getCustNumber() << " "
<< element.getName() << endl;
}
cout << end1;
// Get the customer number to search for.
cout << "Enter a customer number to search for: ";
cin >> searchValue;
// Search for the customer number.
if (binary_search(customers.begin(), customers.end(),
Customer(searchValue, "")))
cout << "That customer is in the vector.\n";
else
cout << "That customer is not in the vector.\n";
return 0;
}

```

\section*{Program Output}

Here are the sorted customers:
1001 Sarah Scott
1002 Austin Hill
1003 Megan Cruz
Enter a customer number to search for: 1001
That customer is in the vector.

\section*{Program Output}

Here are the sorted customers:
1001 Sarah Scott
1002 Austin Hill
1003 Megan Cruz
Enter a customer number to search for: 1009
That customer is not in the vector.

Let's take a closer look at the program:
- Lines 12 through 16 define a vector named customers, initialized with three Customer objects.
- Line 19 calls the sort function to sort the vector. Because the Customer class's overloaded < operator compares customer numbers, the objects in the vector will be sorted by customer number, in ascending order.
- The loop in lines 23 through 27 displays all of the vector's elements.
- Line 31 prompts the user to enter a customer number, and line 32 stores the user's input in the searchValue variable.
- Next, the program searches the vector for an object with the customer number entered by the user. Look carefully at the third argument we are passing to the bi nary_ search() function. The expression Customer(searchValue, " ") constructs a temporary, nameless Customer object that has searchValue's value as the customer number, and "" as the customer name. (Because we are simply using this object to search for an element with a specified customer number, there is no need to provide a meaningful value for the customer name.) The binary_search () function will accept this Customer object as an argument, and it will search the specified range of elements for an object that has a matching customer number. (The binary_search function will use the Customer class's overloaded < operator to determine whether two objects are equal.) If a matching element is found, the function returns true. Otherwise, it returns false.

\section*{Detecting Permutations}

If a range has \(N\) elements, there are \(N\) ! possible arrangements of those elements. Each arrangement is called a permutation. For example, suppose we have a vector with the following integer elements:
\(1,2,3\)
There are three elements in the vector, so there are six possible ways to rearrange the elements. The six possible permutations are:

1, 2, 3
1, 3, 2
2, 1, 3
2, 3, 1
3, 1, 2
3, 2, 1
The STL's is_permutation() function determines whether one range of elements is a permutation of another range of elements. Here is the function's general format:
```

is_permutation(iterator1, iterator2, iterator3)

```

In the general format, iterator1 and iterator2 mark the beginning and end of the first range of elements. The iterator 3 argument marks the beginning of the second range of elements, assumed to have the same number of elements as the first range. The function returns true if the second range is a permutation of the first range, or false otherwise.
Program 17-25 demonstrates the is_permutation() function. It uses the function to determine whether a set of numbers matches the winning lottery numbers.

\section*{Program 17-25}
```

\#include <iostream>
\#include <vector>
\#include <algorithm>
using namespace std;
int main()
{
const int MAX = 5; // Numbers in 1 lottery ticket
vector<int> winning(MAX); // The winning numbers
vector<int> player(MAX); // Numbers on a ticket
// Get the winning numbers.
cout << "Enter the " << MAX << " winning numbers:\n";
for (auto \&element : winning)
{
cout << "> ";
cin >> element;
}
// Get the numbers purchased on a lottery ticket.
cout << "\nEnter your " << MAX << " lottery numbers:\n";
for (auto \&element : player)
{
cout << "> ";
cin >> element;
}
// Check for a winner.
if (is_permutation(winning.begin(), winning.end(),
player.begin()))
cout << "You won the lottery!\n";
else
cout << "Sorry, you did not win.\n";
return 0;
}

```

\section*{Program Output}

Enter the 5 winning numbers:
> 10
\(>25\)
\(>67\)
\(>88\)
\(>93\)
Enter your 5 lottery numbers:
> 25
\(>15\)
> 62
```

Program 17-25 (continued)
> 93
> 88
Sorry, you did not win.

```

\section*{Program Output}
```

Enter the 5 winning numbers:
> 10
$>25$
> 67
> 88
> 93
Enter your 5 lottery numbers:
> 67
$>10$
> 93
$>88$
> 25
You won the lottery!

```

\section*{Plugging Your Own Functions into an Algorithm}

When a C++ program is running, the executable code for each of the functions in that program is stored in memory. You can use the name of a function to get that function's address in memory, in the same way that you can use the name of an array to get that array's address in memory. This capability allows you to get a function pointer, which is a pointer to a function's executable code.

Many of the function templates in the STL are designed to accept function pointers as arguments. This allows you to "plug" one of your own functions into the algorithm. For example, here is the general format of the for_each function:
```

for_each(iterator1, iterator2, function)

```

In the general format, the iterator1 and iterator2 arguments mark the beginning and end of a range of elements. The function argument is the address of a function that accepts an element as its argument (Any value returned from function is ignored). The for_each () function iterates over the range of elements, passing each element as an argument to function.

Program 17-26 demonstrates the for_each() function. The program defines a function named doubleNumber (). The doubleNumber() function accepts a reference to an int as its argument, and it doubles the value of the argument. The program uses the for_each () function to double the value of every element in a vector of integers.

\section*{Program 17-26}
```

\#include <iostream>
\#include <vector>
\#include <algorithm>
using namespace std;

```
```

// Function prototype
void doubleNumber(int \&);
int main()
{
vector<int> numbers = { 1, 2, 3, 4, 5 };
// Display the numbers before doubling.
for (auto element : numbers)
cout << element << " ";
cout << endl;
// Double the value of each vector element.
for_each(numbers.begin(), numbers.end(), doubleNumber);
// Display the numbers before doubling.
for (auto element : numbers)
cout << element << " ";
cout << endl;
return 0;
}
//******************************************************
// The doubleNumber function doubles the value of n. *
//******************************************************
void doubleNumber(int \&n)
{
n = n * 2;
}

```

\section*{Program Output}

12345
246810

Another example is the count_if() function. The general format of the count_if() function is:
```

count_if(iterator1, iterator2, function)

```

In the general format, the iterator 1 and iterator 2 arguments mark the beginning and end of a range of elements. The function argument is the address of a function that accepts an element as its argument, and returns either true or false. (The function should not make changes to the element.) The count_if function iterates over the range of elements, passing each element as an argument to function. The count_if function returns the number of elements for which function returns true.

Program 17-27 demonstrates the count_if() function. The program defines a function named outOfRange(). The outOfRange() function accepts an int as its argument, and it returns true if the argument is less than 0 or greater than 100 . The program uses the count_if () function to determine the number of elements in a vector that are not within the range of 1 through 100.

\section*{Program 17-27}
```

\#include <iostream>
\#include <vector>
\#include <algorithm>
using namespace std;
// Function prototype
bool outOfRange(int);
int main()
{
// Create a vector of ints.
vector<int> numbers = { 0, 99, 120, -33, 10, 8, -1, 101 };
// Get the number of elements that are < 0 or > 100.
int invalid = count_if(numbers.begin(), numbers.end(), outOfRange);
// Display the results.
cout << "There are " << invalid << " elements out of range.\n";
return 0;
}
//*******************************************************************
// The outOfRange function returns true if n is out of range.*
//****************************************************************
bool outOfRange(int n)
{
// Constants for min and max values
const int MIN = 0, MAX = 100;
// Flag to hold the status
bool status;
// Determine whether n out of range.
if (n < MIN || n > MAX)
status = true;
else
status = false;
return status;
}

```

\section*{Program Output}

There are 4 elements out of range.

\section*{Using the STL to Perform Set Operations}

The STL provides a number of function templates for performing the basic set operations you probably learned in math class. Table 17-14 summarizes these methods.

Table 17-14 STL Algorithms to Perform Set Operations
\begin{tabular}{ll} 
Function Template & Description \\
set_union(iterator1, \\
iterator2, iterator3, \\
iterator4, iterator5)
\end{tabular} \begin{tabular}{l} 
Finds the union of two sets. The union of two sets is a set that \\
contains all the elements of both sets, excluding duplicates. \\
The iterator1 and iterator2 arguments mark the beginning \\
and end of the first set. The iterator3 and iterator4 arguments \\
mark the beginning and end of the second set. The iterator5 \\
argument marks the beginning of the container that will hold the \\
union of the two sets.
\end{tabular}

The ranges of elements with which these member functions work can be stored in set containers, vectors, arrays, or any other type of container that supports iterators. Keep in mind, however, the ranges of elements must be sorted in ascending order before you can use any of the functions in Table 17-14 with them. For that reason, the set container is convenient because it automatically sorts its elements.

\section*{Finding the Union of Sets with the set_union Function}

The union of two sets is a set that contains all the elements of both sets, with no duplicates. For example, suppose set 1 contains the values \(1,2,3,4\), and set2 contains the values 3,4 , 5,6 . The union of set1 and set2 would be a set containing the values \(1,2,3,4,5,6\).

You can call the STL algorithm function set_union to get the union of two sets. The function stores the union in a third container. Program 17-28 demonstrates how to use the function.

\section*{Program 17-28}
```

\#include <iostream>
\#include <set>
\#include <algorithm>
\#include <vector>
using namespace std;
int main()
{
// Create two sets.
set<int> set1 = {1, 2, 3, 4};
set<int> set2 = {3, 4, 5, 6};
// Create a vector to hold the union. The
// vector must be large enough to hold both sets.
vector<int> result(set1.size() + set2.size());
// Get the union of the sets. The result vector
// will hold the union, and iter will point to
// the end of the result vector.
auto iter = set_union(set1.begin(), set1.end(),
set2.begin(), set2.end(),
result.begin());
// Resize the result vector to remove unused elements.
result.resize(iter - result.begin());
// Display the result vector's elements
cout << "The union of the sets is:\n";
for (auto element : result)
{
cout << element << " ";
}

```
```

    cout << endl;
    35 return 0;

```
34
36 \}

\section*{Program Output}

The union of the sets is:
123456

Let's take a closer look at Program 17-28:
- Lines 10 and 11 define set 1 and set2, initialized with the values \(1,2,3,4\), and \(3,4,5,6\), respectively.
- Line 15 defines a vector named result. We will use the vector to hold the union of set1 and set2. Notice the value we are passing to the vector constructor: set1.size() + set2.size(). This causes the vector to be large enough to hold both sets. (The vector elements will be initialized with 0 .) Figure 17-6 shows the state of set1, set2, and result at this point in the program.
- Line 18 defines an iterator that can be used with the vector. The name of the iterator is iter.
- Lines 20 through 22 call the set_union function. The function gets the union of set1 and set2, and stores the union in the result vector. The function returns an iterator that is assigned to iter. The iter iterator points to the end of the range of elements in the union. Figure 17-7 shows the state of set1, set2, result, and iter at this point in the program. (Notice the last two elements of the result vector are unused.)
- Line 25 resizes the result vector to remove the unused elements. Figure 17-8 shows the state of set1, set2, result, and iter at this point in the program.
- Lines 28 through 36 display the program's output, which includes the contents of the result vector.

Figure 17-6 State of set1, set2, and result after line 15 has executed

Figure 17-7 State of set1, set2, result, and iter after lines 20 through 22 have executed

Figure 17-8 State of set1, set2, result, and iter after line 25 has executed

\section*{Finding the Intersection of Sets with the set_intersection Function}

The intersection of two sets is a set that contains only the elements that are found in both sets. For example, suppose set 1 contains the values \(1,2,3,4\), and set 2 contains the values \(3,4,5,6\). The intersection of set1 and set 2 would be a set containing the values 3,4 .

You can call the STL algorithm function set_intersection to get the intersection of two sets. The function stores the intersection in a third container. Program 17-29 demonstrates how to use the function.

\section*{Program 17-29}
```

\#include <iostream>
\#include <set>
\#include <algorithm>
\#include <vector>
using namespace std;
int main()
{
// Create two sets.
set<int> set1 = {1, 2, 3, 4};
set<int> set2 = {3, 4, 5, 6};
// Create a vector to hold the intersection. The
// vector must be large enough to hold both sets.
vector<int> result(set1.size() + set2.size());
// Get the intersection of the sets. The result vector
// will hold the intersection, and iter will point to
// the end of the result vector.
auto iter = set_intersection(set1.begin(), set1.end(),
set2.begin(), set2.end(),
result.begin());
// Resize the result vector to remove unused elements.
result.resize(iter - result.begin());
// Display the result vector's elements
cout << "The intersection of the sets is:\n";
for (auto element : result)

```
```

30 {
31 cout << element << " ";
32
33
34
35
return 0;
}

```

\section*{Program Output}

The intersection of the sets is:
34

Let's take a closer look at Program 17-29:
- Lines 10 and 11 define set 1 and set2, initialized with the values \(1,2,3,4\), and 3, \(4,5,6\), respectively.
- Line 15 defines a vector named result. We will use the vector to hold the intersection of set1 and set2. Notice the value we are passing to the vector constructor: set1.size() + set2.size(). This causes the vector to be large enough to hold both sets. (The vector elements will be initialized with 0 .)
- Line 18 defines an iterator that can be used with the vector. The name of the iterator is iter.
- Lines 20 through 22 call the set_intersection function. The function gets the intersection of set1 and set2, and stores the intersection in the result vector. The function returns an iterator that is assigned to iter. The iter iterator points to the end of the range of elements in the intersection.
- Line 25 resizes the result vector to remove any unused elements.
- Lines 28 through 33 display the program's output, which includes the contents of the result vector.

\section*{Finding the Difference of Sets with the set_difference Function}

The difference of two sets is the set of elements that appear in the first set, but not the second set. For example, suppose set1 contains the values \(1,2,3,4\), and set2 contains the values \(3,4,5,6\). The difference of set1 and set 2 would be a set containing the values 1,2 .

You can call the STL algorithm function set_difference to get the difference of two sets. The function stores the difference in a third container. Program 17-30 demonstrates how to use the function.

\section*{Program 17-30}
```

\#include <iostream>
\#include <set>
\#include <algorithm>
\#include <vector>
using namespace std;
int main()

```

\section*{Program 17-30 (continued)}
```

{
// Create two sets.
0 set<int> set1 = {1, 2, 3, 4};
return 0;
}

```
11
12
13
14
15
16
17
18

\section*{Program Output}

The difference of set1 and set2 is:
12
Let's take a closer look at Program 17-30:
- Lines 10 and 11 define set 1 and set2, initialized with the values \(1,2,3,4\), and \(3,4,5,6\), respectively.
- Line 15 defines a vector named result. We will use the vector to hold the difference of set1 and set2. Notice the value we are passing to the vector constructor: set1.size() + set2.size(). This causes the vector to be large enough to hold both sets. (The vector elements will be initialized with 0 .)
- Line 18 defines an iterator that can be used with the vector. The name of the iterator is iter.
- Lines 20 through 22 call the set_difference function. The function gets the difference of set1 and set2, and stores the difference in the result vector. The function returns an iterator that is assigned to iter. The iter iterator points to the end of the range of elements in the difference.
- Line 25 resizes the result vector to remove any unused elements.
- Lines 28 through 33 display the program's output, which includes the contents of the result vector.

\section*{Finding the Symmetric Difference of Sets with the set_symmetric_difference Function}

The symmetric difference of two sets is the set of elements that are in either set, but not in both. For example, suppose set 1 contains the values \(1,2,3,4\), and set 2 contains the values \(3,4,5,6\). The symmetric difference of set 1 and set 2 would be a set containing the values \(1,2,5,6\).

You can call the STL algorithm function set_symmetric_difference to get the symmetric difference of two sets. The function stores the symmetric difference in a third container. Program 17-31 demonstrates how to use the function.

\section*{Program 17-31}
```

\#include <iostream>
\#include <set>
\#include <algorithm>
\#include <vector>
using namespace std;
int main()
{
// Create two sets.
set<int> set1 = {1, 2, 3, 4};
set<int> set2 = {3, 4, 5, 6};
// Create a vector to hold the symmetric difference.
// The vector must be large enough to hold both sets.
vector<int> result(set1.size() + set2.size());
// Get the symmetric difference of the sets. The result
// vector will hold the symmetric difference, and iter
// will point to the end of the result vector.
auto iter = set_symmetric_difference(set1.begin(), set1.end(),
set2.begin(), set2.end(),
result.begin());
// Resize the result vector to remove unused elements.
result.resize(iter - result.begin());
// Display the result vector's elements
cout << "The symmetric difference of the sets is:\n";
for (auto element : result)
{
cout << element << " ";
}
cout << endl;
return 0;
}

```

\section*{Program Output}

The symmetric difference of the sets is:
1256

Let's take a closer look at Program 17-31:
- Lines 10 and 11 define set1 and set2, initialized with the values \(1,2,3,4\), and \(3,4,5,6\), respectively.
- Line 15 defines a vector named result. We will use the vector to hold the difference of set1 and set2. Notice the value we are passing to the vector constructor: set1.size() + set2.size(). This causes the vector to be large enough to hold both sets. (The vector elements will be initialized with 0 .)
- Line 18 defines an iterator that can be used with the vector. The name of the iterator is iter.
- Lines 20 through 22 call the set_symmetric_difference function. The function gets the symmetric difference of set1 and set2, and stores the symmetric difference in the result vector. The function returns an iterator that is assigned to iter. The iter iterator points to the end of the range of elements in the symmetric difference.
- Line 25 resizes the result vector to remove any unused elements.
- Lines 28 through 33 display the program's output, which includes the contents of the result vector.

\section*{Finding Subsets}

Suppose you have two sets and one of those sets includes all of the elements of the other set. For example, suppose set 1 contains the values \(1,2,3,4\), and set 2 contains the values 2,3 . In this example, set1 contains all of the elements of set2, which means that set2 is a subset of set1.

You can call the STL function includes to determine whether one set includes all of the elements of another set. You use iterators to pass two sorted ranges of elements to the includes function, and the function returns true if the first range includes all of the elements in the second range. Otherwise, the function returns false. Program 17-32 demonstrates how to use the function. The program determines whether the elements in set1 include all of the elements in set2.

\section*{Program 17-32}
```

\#include <iostream>
\#include <set>
\#include <algorithm>
using namespace std;
int main()
{
// Create two sets.
set<int> set1 = {1, 2, 3, 4};
set<int> set2 = {2, 3};
// Determine whether set1 includes the
// elements of set2.
if (includes(set1.begin(), set1.end(),
set2.begin(), set2.end()))
{
cout << "set2 is a subset of set1.\n";
}

```
```

    else
    {
        cout << "set2 is NOT a subset of set1.\n";
    }
    return 0;
    }

```

\section*{Program Output}
set2 is a subset of set1.

\section*{In the Spotlight:}

\section*{Set Operations}

In this section, you will look at Program 17-33, which demonstrates various set operations. The program creates two sets: one that holds the names of students on the baseball team, and another that holds the names of students on the basketball team. The program then performs the following operations:
- It finds the intersection of the sets to display the names of students who play both sports.
- It finds the union of the sets to display the names of students who play either sport.
- It finds the difference of the baseball and basketball sets to display the names of students who play baseball but not basketball.
- It finds the difference of the basketball and baseball (basketbal1-baseball) sets to display the names of students who play basketball but not baseball. It also finds the difference of the baseball and basketball (baseball-basketball) sets to display the names of students who play baseball but not basketball.
- It finds the symmetric difference of the basketball and baseball sets to display the names of students who play one sport but not both.

\section*{Program 17-33}
```

\#include <iostream>
\#include <string>
\#include <algorithm>
\#include <set>
\#include <vector>
using namespace std;
// Function prototypes
void displaySet(set<string>);
void displayIntersection(set<string>, set<string>);
void displayUnion(set<string>, set<string>);
void displayDifference(set<string>, set<string>);
void displaySymmetricDifference(set<string>, set<string>);

```

\section*{Program 17-33 (continued)}
```

int main()
{
// Create sets for the basebal1 \& basketbal1 teams.
set<string> basebal1 = {"Jodi", "Carmen", "Aida", "Alicia"};
set<string> basketba11 = {"Eva", "Carmen", "Alicia", "Sarah"};
// Display the elements of the baseball set.
cout << "The following students are on the baseball team:\n";
displaySet(baseba11);
// Display the elements of the basketball set.
cout << "\n\nThe following students are on the basketball team:\n";
displaySet(basketba11);
// Display the intersection of the two sets.
cout << "\n\nThe following students play both sports:\n";
displayIntersection(basebal1, basketbal1);
// Display the union of the two sets.
cout << "\n\nThe following students play either sport:\n";
displayUnion(basebal1, basketbal1);
// Display the difference of basebal1 and basketbal1.
cout << "\n\nThe following students play baseball, "
<< "but not basketbal1:\n";
displayDifference(baseba11, basketba11);
// Display the difference of basketbal1 and basebal1.
cout << "\n\nThe following students play basketball, "
<< "but not baseball:\n";
displayDifference(basketba11, basebal1);
// Display the symmetric difference of the two sets.
cout << "\n\nThe following students play one sport, "
<< "but not both:\n";
displaySymmetricDifference(basketba11, basebal1);
return 0;
}
// The displaySet function displays the contents of a set<string>.
void displaySet(set<string> s)
{
for (auto element : s)
cout << element << " ";
}
// The displayIntersection function displays the intersection
// of two set<string> objects.
void displayIntersection(set<string> set1, set<string> set2)

```
```

    // Create a vector to hold the intersection.
    vector<string> result(set1.size() + set2.size());
    // Get the intersection of the sets.
    auto iter = set_intersection(set1.begin(), set1.end(),
                                    set2.begin(), set2.end(),
                                    result.begin());
    // Resize the result vector to remove unused elements.
    result.resize(iter - result.begin());
    // Display the result vector's elements
    for (auto element : result)
    {
        cout << element << " ";
    }
    }
// The displayUnion function displays the union of two
// set<string> objects.
void displayUnion(set<string> set1, set<string> set2)
{
// Create a vector to hold the union.
vector<string> result(set1.size() + set2.size());
// Get the union of the sets.
auto iter = set_union(set1.begin(), set1.end(),
set2.begin(), set2.end(),
result.begin());
// Resize the result vector to remove unused elements.
result.resize(iter - result.begin());
// Display the result vector's elements
for (auto element : result)
{
cout << element << " ";
}
}
// The displayDifference function displays the difference
// of two set<string> objects.
void displayDifference(set<string> set1, set<string> set2)
{
// Create a vector to hold the union.
vector<string> result(set1.size() + set2.size());
// Get the difference of the sets.
auto iter = set_difference(set1.begin(), set1.end(),
set2.begin(), set2.end(),
result.begin());

```

\section*{Program 17-33 (continued)}
```

    // Resize the result vector to remove unused elements.
    result.resize(iter - result.begin());
    // Display the result vector's elements
    for (auto element : result)
    {
        cout << element << " ";
    }
    }
// The displaySymmetricDifference function displays the
// symmetric difference of two set<string> objects.
void displaySymmetricDifference(set<string> set1, set<string> set2)
{
// Create a vector to hold the union.
vector<string> result(set1.size() + set2.size());
// Get the symmetric difference of the sets.
auto iter = set_symmetric_difference(set1.begin(), set1.end(),
set2.begin(), set2.end(),
result.begin());

result.resize(iter - result.begin());
// Display the result vector's elements
for (auto element : result)
{
cout << element << " ";
}
}

```

\section*{Program Output}

The following students are on the baseball team:
Aida Alicia Carmen Jodi
The following students are on the basketball team:
Alicia Carmen Eva Sarah
The following students play both sports:
Alicia Carmen
The following students play either sport:
Aida Alicia Carmen Eva Jodi Sarah
The following students play baseball, but not basketbal1:
Aida Jodi
The following students play basketball, but not baseball:
Eva Sarah
The following students play one sport, but not both:
Aida Eva Jodi Sarah

\section*{Checkpoint}
17.36 When a range of elements is denoted by two iterators, to what does the first iterator point? To what does the second iterator point?
17.37 What value will be stored in \(\mathrm{v}[0]\) after the following code executes?
```

vector<int> v = {8, 4, 6, 1, 9};

```
sort(v.begin(), v.end());
17.38 What must you do to a range of elements before searching it with the binary_ search() function?
17.39 If the elements that you are sorting with the sort() function contain your own class objects, you must be sure that the class overloads what operator?
17.40 If the elements that you are searching with the binary_search () function contain your own class objects, you must be sure that the class overloads what operator?
17.41 What is a function pointer?
17.42 Assume vect is a vector that contains 100 int elements, and the following statement appears in a program:
for_each(vect.begin(), vect.end(), myFunction);
Without knowing anything else about the program, answer the following questions:
A) What is myFunction?
B) How many arguments does myFunction accept? What are the data type(s) of the argument(s)?
C) What value does myFunction return?
D) How many times will the statement cause myFunction to be called?

\subsection*{17.7 Introduction to Function Objects and Lambda Expressions}

CONCEPT: A function object is an object of a class that overloads the function call operator. Function objects behave just like functions, and can be passed as parameters to other functions. A lambda expression is a convenient way of creating a function object.

VideoNote
Function Objects and Lambda Expressions

A function object, also known as a functor, is an object that acts like a function. Function objects can be called, just like regular functions. They can accept arguments, and they can return values. To create a function object, you write a class that overloads the parentheses () operator, which is also known as the function call operator. Let's look at a simple example, the Sum class.

\section*{Contents of Sum.h}
```

\#ifndef SUM_H
\#define SUM_H
class Sum
{
public:
int operator()(int a, int b)
{ return a + b; }
};
\#endif

```

The Sum class has one member function: the operator() function. When you write an operator() function, the function can have as many parameter variables as necessary. Notice in the Sum class, the operator () function has two int parameter variables: a and b. Also, notice in the Sum class the operator() function returns an int. The value it returns is the sum of a and b. Program 17-34 demonstrates the Sum class.

\section*{Program 17-34}
```

\#include <iostream>
\#include "Sum.h"
using namespace std;
int main()
{
// Local variables
int x = 10;
int y = 2;
int z = 0;
// Create a Sum object.
Sum sum;
// Call the sum function object.
z = sum(x, y);
// Display the result.
cout << z << endl;
return 0;
}

```

\section*{Program Output}

Let's take a closer look at Program 17-34:
- Lines 8 through 10 define three local int variables: \(x, y\), and \(z\).
- Line 13 creates an instance of the Sum class. The object's name is sum.
- Line 16 calls the sum object, as if it were a function. The statement passes x and y as arguments, and assigns the return value to the \(z\) variable.
- Line 19 displays the \(z\) variable.

In the previous section on STL algorithms, you saw examples of STL function templates that accept function pointers as arguments, allowing you to plug one of your own functions into the algorithm. If you prefer, you can pass a function object instead of a function pointer to any of these STL algorithms.

Let's look at an example, using the count_if() function. Recall the count_if() function iterates over a range of elements, passing each element as an argument to a function that you provide. The function you provide must accept one argument, and return either true or false. You can provide the function as either a function pointer, or a function object. The count_if function returns the number of elements for which function returns true. We will use a function object along with the count_if() function to count the number of even numbers that appear in a vector. Our function object will be an instance of the IsEven class, shown here:

\section*{Contents of IsEven.h}
```

\#ifndef IS_EVEN_H
\#define IS_EVEN_H
class IsEven
{
public:
bool operator()(int x)
{ return x % 2 == 0; }
};
\#endif

```

The IsEven class has one member function: the operator() function. The operator() function has one int parameter variable, x . The function returns true if x is an even number, or false otherwise. Program 17-35 creates an instance the IsEven class, and uses it as a function object with the count_if() function.

\section*{Program 17-35}
```

\#include <iostream>
\#include <vector>
\#include <algorithm>
\#include "IsEven.h"
using namespace std;
int main()
{
// Create a vector of ints.
vector<int> v = { 1, 2, 3, 4, 5, 6, 7, 8 };
// Create an instance of the IsEven class.
IsEven isNumberEven;
// Get the number of elements that even.
int evenNums = count_if(v.begin(), v.end(), isNumberEven);

```

\section*{Program 17-35 (continued)}
```

18 // Display the results.
19 cout << "The vector contains " << evenNums << " even numbers.\n";
20 return 0;
21 }

```

\section*{Program Output}

The vector contains 4 even numbers.

\section*{Constructing an Anonymous Function Object}

In line 13 of Program 17-35, we created an instance of the IsEven class, and we named it isNumberEven. Then, in line 16 we passed the object to the count_if() function. Function objects can be called at the point of their creation, however, without ever being given a name. For example, the following code creates an IsEven function object and calls it with the argument 2 , without ever giving the function object a name:
```

if (IsEven(2))
cout << "The number is even.\n";
else
cout << "The number is not even.\n";

```

Objects that are created and used without being given a name are said to be anonymous. Program 17-36 is similar to Program 17-35, except that an anonymous instance of the IsEven class is passed to the count_if() function.

\section*{Program 17-36}
```

\#include <iostream>
\#include <vector>
\#include <algorithm>
\#include "IsEven.h"
using namespace std;
int main()
{
// Create a vector of ints.
vector<int> v = { 1, 2, 3, 4, 5, 6, 7, 8 };
// Get the number of elements that even.
int evenNums = count_if(v.begin(), v.end(), IsEven());
// Display the results.
cout << "The vector contains " << evenNums << " even numbers.\n";
return 0;
}

```

\section*{Program Output}

The vector contains 4 even numbers.

\section*{Predicate Terminology}

A function or function object that returns a Boolean value is called a predicate. A predicate that takes only one argument is called a unary predicate. (An instance of the IsEven class, previously shown, would be a unary predicate.) A predicate that takes two arguments is called a binary predicate. It is important that you are familiar with this terminology because it is used in much of the available C++ documentation and literature.

\section*{Lambda Expressions}

A lambda expression is a compact way of creating a function object without having to write a class declaration. It is an expression that contains only the logic of the object's operator() member function. When the compiler encounters a lambda expression, it automatically generates a function object in memory, using the code that you provide in the lambda expression for the operator () member function.

Typically, a lambda expression takes the following general format:
```

[](parameter list) { function body }

```

The [] at the beginning of the expression is known as the lambda introducer. It marks the beginning of a lambda expression. The parameter 1 ist is a list of parameter declarations for the function object's operator() member function, and the function body is the code that should be the body of the object's operator () member function.

For example, the lambda expression for a function object that computes the sum of two integers is:
```

[](int a, int b) { return x + y; }

```

And, the lambda expression for a function object that determines whether an integer is even is:
```

[](int x) { return x % 2 == 0; }

```

As another example, the lambda expression that takes an integer as input and prints the square of that integer is written like this:
```

[](int a) { cout << a * a << " "; }

```

NOTE: Optionally, a capture list can appear inside the brackets [] of a lambda expression. A capture list is a list of variables in the surrounding scope of the lambda expression that can be accessed from the lambda's function body.

When you call a lambda expression, you write a list of arguments, enclosed in parentheses, right after the expression. For example, the following code snippet displays 7, which is the sum of the variables \(x\) and \(y\) :
```

int x = 2;
int y = 5;
cout << [](int a, int b) {return a + b;}(x, y) << endl;

```

The following code segment counts the even numbers in a vector, in the manner of Program 17-36. However, it uses a lambda expression in place of the IsEven() function object as the third argument to the count_if() function.
```

// Create a vector of ints.
vector<int> v = { 1, 2, 3, 4, 5, 6, 7, 8 };
// Get the number of elements that are even.
int evenNums = count_if(v.begin(), v.end(), [](int x) {return x % 2 == 0;});
// Display the results.
cout << "The vector contains " << evenNums << " even numbers.\n";

```

Because lambda expressions generate function objects, you can assign a lambda expression to a variable of a suitable type then call it through the variable's name. For example, the lambda expression shown in the following code gives us a function object that adds two integers. The function object is assigned to a variable named sum:
```

auto sum = [](int a, int b) {return a + b;};

```

Once the statement has executed, we can use the sum variable to call the function object, as shown here:
```

int x = 2;
int y = 5;
int z = sum(x, y);

```

After this code has executed, the variable \(z\) will be assigned 7. Program 17-37 shows another example. It is similar to Program 17-36, except that a lambda expression (which determines whether a value is even) is assigned to a variable named isEven, and that variable is passed as the third argument to the count_if() function.

\section*{Program 17-37}
```

\#include <iostream>
\#include <vector>
\#include <algorithm>
using namespace std;
int main()
{
// Create a vector of ints.
vector<int> v = { 1, 2, 3, 4, 5, 6, 7, 8 };
// Use a lambda expression to create a function object.
auto isEven = [](int x) { return x % 2 == 0; };
// Get the number of elements that even.
int evenNums = count_if(v.begin(), v.end(), isEven);
// Display the results.
cout << "The vector contains " << evenNums << " even numbers.\n";
return 0;
}

```

\section*{Program Output}

The vector contains 4 even numbers.

\section*{Functional Classes in the STL}

Function objects are so useful the C++ library defines a number of classes that you can instantiate to create function objects in your program. To use these classes, you must \#include the <functional> header file. Table 17-15 lists those that can be used to compare objects, but you can find information on many more in various resources online.

Table 17-15 STL Function Object Classes
\begin{tabular}{|c|c|}
\hline Functional Class & Description \\
\hline \(1 \mathrm{ess}<\mathrm{T}>\) & less<T>() (Ta, T b ) is true if and only if \(\mathrm{a}<\mathrm{b}\) \\
\hline 1ess_equal<T> & 1ess_equal () ( \(T\) a, \(T\) b) is true if an only if \(\mathrm{a}<=\mathrm{b}\) \\
\hline greater<T> & greater \(<T>()(T a, T b)\) is true if and only if \(a>b\) \\
\hline greater_equal<T> & greater_equal<T>() ( \(T\) a, \(T\) b \()\) is true if and only if \(a>=b\) \\
\hline
\end{tabular}

For example, the STL sort function normally sorts the elements in a range in ascending order. This is because the sort function, by default, uses the < operator to compare elements. But what if you want to use the function to sort a range of elements in descending order? All you have to do is make the function use the > operator instead.
As it turns out, the sort function takes a comparison function as an optional third argument. The argument can be a function pointer or a function object. The function must accept two arguments (of the same type as the range elements), and must return a Boolean value. When you pass a comparison function as the third argument to the sort function, the sort function will use the comparison function instead of the < operator to compare range elements. To make the sort function use the > operator, you can pass an instance of the greater \(<T>\) class as the comparison function. Program 17-38 demonstrates how this can be done to sort a vector in descending order.

\section*{Program 17-38}
```

\#include <iostream>
\#include <vector>
\#include <functional>
\#include <algorithm>
using namespace std;
int main()
{
// Create an unsorted vector of ints.
vector<int> v = {8, 1, 7, 2, 6, 3, 5, 4};
// Display the vector contents.
cout << "Original order:\n";
for (auto element : v)
cout << element << " ";
// Sort the vector in ascending order.
sort(v.begin(), v.end());

```

\section*{Program 17-38 (continued)}
```

    // Display the vector contents again.
    cout << "\nAscending order:\n";
    for (auto element : v)
        cout << element << " ";
    // Sort the vector in descending order.
    sort(v.begin(), v.end(), greater<int>());
    // Display the vector contents again.
    cout << "\nDescending order:\n";
    for (auto element : v)
    cout << element << " ";
    cout << endl;
    return 0;
    }

```

\section*{Program Output}

Original order:
81726354
Ascending order:
12345678
Descending order:
87654321

\section*{(1) Checkpoint}
17.43 What is a function object?
17.44 Which operator must be overloaded in a class before the class can be used to create function objects?
17.45 What is an anonymous function object?
17.46 What is a predicate?
17.47 What is a unary predicate?
17.48 What is a binary predicate?
17.49 What is a lambda expression?

\section*{Review Questions and Exercises}

\section*{Short Answer}
1. What two emplacement member functions are provided by the vector class? How are these member functions different from the insert() and push_back() member functions?
2. What is the difference between the vector class's size() member function and the capacity() member function?
3. If you want to store objects of a class that you have written as values in a map, what requirement must the class meet?
4. If you want to store objects of a class that you have written as keys in a map, what requirement must the class meet?
5. What is the difference between a map and an unordered_map?
6. What is the difference between a map and a multimap?
7. What happens if you use the insert () member function to insert a value into a set, and that value already exists in the set?
8. If you want to store objects of a class that you have written as keys in a set, what requirement must the class meet?
9. What is the difference between a set and a multiset?
10. How does the behavior of the count () member function differ between the set class and the multiset class?
11. How does the behavior of the equal_range() member function differ between the set class and the multiset class?
12. What are two differences between the set and unordered_set classes?
13. When using one of the STL algorithm function templates, you typically work with a range of elements that are denoted by two iterators, to what does the first iterator point? To what does the second iterator point?
14. You have written a class, and you plan to store objects of that class in a vector. If you plan to use the sort () and/or binary_search() functions on the vector's elements, what operator must the class overload?
15. What is a function object?
16. If you want to create function objects from a class, what must the class overload?
17. What is an anonymous function object?
18. What is a lambda expression?

\section*{Fill-in-the-Blank}
19. There are two types of container classes in the STL: \(\qquad\) and \(\qquad\) .
20. A(n) \(\qquad\) container organizes data in a sequential fashion similar to an array.
21. A container \(\qquad\) class is not itself a container, but a class that adapts a container to a specific use.
22. \(\mathrm{A}(\mathrm{n})\) \(\qquad\) container stores its data in a nonsequential way that makes it faster to locate elements.
23. \(\qquad\) are pointer-like objects used to access data stored in a container.
24.

Each element that is stored in a map has two parts: a \(\qquad\) and a \(\qquad\) .
25. \(\qquad\) is a map container that allows duplicate keys.
26. The \(\qquad\) class is an associative container that stores a collection of unique, sorted values.
27. The \(\qquad\) header file defines several function templates that implement useful algorithms.
28. A \(\qquad\) is a pointer to a function's executable code.
29. A \(\qquad\) object is an object that can be called, like a function.
30. A \(\qquad\) is a function or function object that returns a Boolean value.
31. A \(\qquad\) is a predicate that takes one argument.
32. A \(\qquad\) is a predicate that takes two arguments.
33. A \(\qquad\) is a compact way of creating a function object without having to write a class declaration.

\section*{True or False}
34. \(\mathrm{T} \quad \mathrm{F}\) The array class is a fixed-size container.
35. T F The vector class is a fixed-size container.
36. T F You use the * operator to dereference an iterator.
37. T F You can use the ++ operator to increment an iterator.
38. T F A container's end () member function returns an iterator pointing to the last element in the container.
39. \(\mathrm{T} \quad \mathrm{F}\) A container's rbegin() member function returns a reverse iterator pointing
to the first element in a container.
40. T F You do not have to declare the size of a vector when you define it.
41. T F A vector uses an array internally to store its elements.
42. T F A map is a sequence container.
43. \(\mathrm{T} \quad \mathrm{F}\) You can store duplicate keys in a map container.
44. T F The mu7timap class's erase () member function erases only one element at a time. If you want to erase multiple elements that all have the same key, you will have to call the erase () member function multiple times.
45. T F All the elements in a set must be unique.
46. T F The elements in a set are sorted in ascending order.
47. \(\mathrm{T} \quad \mathrm{F}\) If the same value appears more than once in the initialization list of a set definition, an exception will occur at runtime.
48. T F The unordered_set container has better performance than the set container.
49. T F If two iterators denote a range of elements that will be processed by an STL algorithm function, the element pointed to by the second iterator is not included in the range.
50. T F You must sort a range of elements before searching it with the binary_ search () function.
51. T F Any class that will be used to create function objects must overload the operator [] member function.
52. T F Writing a lambda expression usually requires more code than writing a function object's class declaration and then instantiating the class.
53. \(\mathrm{T} \quad \mathrm{F}\) You can assign a lambda expression to a variable, and then use the variable to call the lambda expression's function object.

\section*{Algorithm Workbench}
54. Write a statement that defines an array object named numbers that can hold ten elements of the double data type.
55. Write a statement that defines an iterator that can be used with the array object that you defined in question 54. The iterator's name should be it.
56. Write a statement that defines a vector named numbers that can hold elements of the int data type. Initialize the vector with the values \(10,20,30,40\), and 50 .
57. The following statement defines a vector of ints named \(v\). Write a statement that defines another vector, named \(v 2\), which is a copy of \(v\).
vector<int> v = \{1, 2, 3, 4, 5\};
58. Write a range-based for loop that displays all of the elements of the vector that you defined in question 56.
59. Write a for loop that uses an iterator to display all of the elements of the vector that you defined in question 56.
60. The following code defines a vector and an iterator. Rewrite the statement that defines the iterator so it uses the auto key word.
vector<string> strv \(=\) \{"one", "two", "three"\};
vector<string>::iterator it = strv.begin();
61. The following statement defines a vector of ints named \(v\). Write a statement that defines a const_iterator named cit, and initializes it to point to the first element in \(v\).
vector<int> v = \{1, \(2,3,4,5\}\);
62. The following statement defines a vector of ints named v . The vector's initial contents are: \(1,2,3,4,5\). Write code to insert the value 999 into the vector, so its contents are: \(1,2,999,3,4,5\).
vector<int> v = \{1, 2, 3, 4, 5\};
63. Write a statement that defines a map named food. The keys should be strings, and the values should be ints.
64. Suppose a program defines a map as follows:
map<int, string> customers;
Write statements that use the map class's emplace member function to insert the following elements:
9001, "Jen Williams"
9002, "Frank Smith"
9003, "Geri Rose"
65. Look at the following vector definition:
vector<int> v = \(\{7,2,1,6,4,3,5\}\);
Write code that displays a message indicating whether the value 6 is found in the vector. Use the STL binary_search() algorithm to search the vector for the value 6 .
66. Write a declaration for a class named Display. The class should be written in such a way that it can be used to create a function object. A function object created from the class should accept an int argument, and display that argument on the screen.
67. Write code that does the following:
- Uses a lambda expression that accepts two int arguments, \(a\) and \(b\), and returns the value of \(a{ }^{*} b\).
- Assigns the lambda expression to a variable named multiply.
- Uses the multiply variable to call the lambda expression, passing the values 2 and 10 as arguments. The result should be assigned to an int variable named product.

\section*{Find the Errors}

Each of the following code snippets has errors. Find as many as you can.
68. // This code has an error. array<int, 5> a;
\(a[5]=99\);
69. // This code has an error.
vector<string> strv = \{"one", "two", "three"\};
vector<string>::iterator it = strv.cbegin();
70. // This code has an error.
vector<int> numbers(10);
for (int index \(=0\); index < numbers.length(); index++) numbers[index] = index;
71. // This code has an error.
vector<int> numbers \(=\{1,2,3\}\);
numbers.insert(99);
72. // This code has an error. map<string, string> contacts;
contacts.insert("Beth Young", "555-1212);
73. // This code has an error.
multimap<string, string> phonebook;
phonebook["Megan"] = "555-1212";
74. // This code has an error.
vector<int> \(v=\{6,5,4,2,3,1\}\);
sort(v);
if (binary_search(v, 1))
cout << "The value 1 is found in the vector. \(\ln\) ";
else
cout << "The value 1 is NOT found in the vector. 1 n ";
75. // This code has an error.

\section*{Programming Challenges}
1. Unique Words

Write a program that opens a specified text file then displays a list of all the unique words found in the file.
Hint: Store each word as an element of a set.

VideoNote

The Course Information Problem

\section*{2. Course Information}

Write a program that creates a map containing course numbers and the room numbers of the rooms where the courses meet. The map should have the following key-value pairs:
\begin{tabular}{ll}
\hline Course Number (Key) & Room Number (Value) \\
\hline CS101 & 3004 \\
CS102 & 4501 \\
CS103 & 6755 \\
NT110 & 1244 \\
CM241 & 1411 \\
\hline
\end{tabular}

The program should also create a map containing course numbers and the names of the instructors that teach each course. The map should have the following key-value pairs:
\begin{tabular}{ll}
\hline Course Number (Key) & Instructor (Value) \\
\hline CS101 & Haynes \\
CS102 & Alvarado \\
CS103 & Rich \\
NT110 & Burke \\
CM241 & Lee \\
\hline
\end{tabular}

The program should also create a map containing course numbers and the meeting times of each course. The map should have the following key-value pairs:
\begin{tabular}{ll}
\hline Course Number (Key) & Meeting Time (Value) \\
\hline CS101 & 8:00 a.m. \\
CS102 & 9:00 a.m. \\
CS103 & 10:00 a.m. \\
NT110 & 11:00 a.m. \\
CM241 & 1:00 p.m. \\
\hline
\end{tabular}

The program should let the user enter a course number, then it should display the course's room number, instructor, and meeting time.

\section*{3. Tokenized Strings to JSON}

The JSON (JavaScript Object Notation) format is becoming more and more popular. The format is quite flexible, but in its most basic format everything is expressed as key-value pairs in the format "key": "value", with pairs delimited by a comma, like \{"book": "C++", "author": "Gaddis", "chapters": " 21 "\}. Write a program that first creates a map from the values in the file challenge3.txt and prints out the (simplified) JSON format described above.

\section*{4. File Encryption and Decryption}

Write a program that uses a map to assign "codes" to each letter of the alphabet. For example:
```

map<char, char> codes =
{ {'A', '%'}, {'a', '9'}, {'B', '@'}, {'b', '\#'}, etc ...};

```

Using this example, the letter 'A' would be assigned the symbol \(\%\), the letter ' \(a\) ' would be assigned the number 9 , the letter ' B ' would be assigned the symbol @, and so forth. The program should open a specified text file, read its contents, then use the map to write an encrypted version of the file's contents to a second file. Each character in the second file should contain the code for the corresponding character in the first file. Write a second program that opens an encrypted file and displays its decrypted contents on the screen.

\section*{5. Text File Analysis}

Write a program that reads the contents of two text files and compares them in the following ways:
- It should display a list of all the unique words contained in both files.
- It should display a list of the words that appears in both files.
- It should display a list of the words that appears in the first file, but not the second.
- It should display a list of the words that appears in the second file, but not the first.
- It should display a list of the words that appears in either the first or second file, but not in both.
Hint: Use set operations to perform these analyses. Also, see Chapter 10 for a discussion of string tokenizing.

\section*{6. Word Frequency}

Write a program that reads the contents of a text file. The program should create a map in which the keys are the individual words found in the file and the values are the number of times each word appears. For example, if the word "the" appears 128 times, the map would contain an element with "the" as the key and 128 as the value. The program should either display the frequency of each word or create a second file containing a list of each word and its frequency.
Hint: See Chapter 10 for a discussion of string tokenizing.

\section*{7. Word Index}

Write a program that reads the contents of a text file. The program should create a map in which the key-value pairs are described as follows:
- Key-The keys are the individual words found in the file.
- Values-Each value is a set that contains the line numbers in the file where the word (the key) is found.
For example, suppose the word "robot" is found in lines 7, 18, 94, and 138. The map would contain an element in which the key was the string "robot", and the value was a set containing the numbers \(7,18,94\), and 138 .
Once the map is built, the program should create another text file, known as a word index, listing the contents of the map. The word index file should contain an alphabetical listing of the words that are stored as keys in the map, along with the line numbers where the words appears in the original file. Figure 17-9 shows an example of an original text file (Kennedy.txt) and its index file (index.txt).
Hint: See Chapter 10 for a discussion of string tokenizing.

Figure 17-9 Example original file and index file

\section*{8. Prime Number Generation}

A positive integer greater than 1 is said to be prime if it has no divisors other than 1 and itself. A positive integer greater than 1 is composite if it is not prime. Write a program that asks the user to enter an integer greater than 1 , then displays all of the prime numbers that are less than or equal to the number entered. The program should work as follows:
- Once the user has entered a number, the program should populate a vector with all of the integers from 2 , up through the value entered.
- The program should then use the STL's for_each function to step through the vector. The for_each function should pass each element to a function object that displays the element if it is a prime number.

\section*{9. Gas Prices}

In the student sample program files for this chapter, you will find a text file named GasPrices.txt. The file contains the weekly average prices for a gallon of gas in the U.S., beginning on April 5, 1993, and ending on August 26, 2013. Figure 17-10 shows an example of the first few lines of the file's contents.

Figure 17-10 The GasPrices.txt file
\begin{tabular}{|llll|}
\hline- GasPrices.txt - Notepad & - & \(\square\) & \(\times\) \\
File Edit Format View & Help & & \\
\hline \(04-05-1993: 1.068\) & & & \\
\(04-12-1993: 1.079\) & & & \\
\(04-19-1993: 1.079\) & & & \\
\(04-26-1993: 1.086\) & & & \\
\(05-03-1993: 1.086\) & & & \\
\(05-10-1993: 1.097\) & & & \(\checkmark\) \\
\(05-17-1993: 1.106\) & & & \(\rangle\) \\
\hline & & Ln 1, Col \\
\hline
\end{tabular}

Each line in the file contains the average price for a gallon of gas on a specific date. Each line is formatted in the following way:

MM-DD-YYYY:Price
\(M M\) is the two-digit month, \(D D\) is the two-digit day, and \(Y Y Y Y\) is the four-digit year. Price is the average price per gallon of gas on the specified date.
For this assignment, you are to write one or more programs that read the contents of the file and perform the following calculations:
Average Price Per Year: Calculate the average price of gas per year, for each year in the file. (The file's data starts in April of 1993, and it ends in August 2013. Use the data that is present for the years 1993 and 2013.)

Average Price Per Month: Calculate the average price for each month in the file.
Highest and Lowest Prices Per Year: For each year in the file, determine the date and amount for the lowest price, and the highest price.
List of Prices, Lowest to Highest: Generate a text file that lists the dates and prices, sorted from the lowest price to the highest.
List of Prices, Highest to lowest: Generate a text file that lists the dates and prices, sorted from the highest price to the lowest.
You can write one program to perform all of these calculations, or you can write different programs, one for each calculation. Regardless of the approach that you take, you should read the contents of the GasPrices.txt file, and extract its data into one or more STL containers appropriate for your algorithm.
Hint: See Chapter 10 for a discussion of string tokenizing.

\section*{\(\square \square \square \square \square \square \square\)}

TOPICS
18.1 Introduction to the Linked List ADT
18.2 Linked List Operations
18.3 A Linked List Template
18.4 Variations of the Linked List
18.5 The STL 1 ist and forward_1ist Containers

\subsection*{18.1 Introduction to the Linked List ADT}

\section*{CONCEPT: Dynamically allocated data structures may be linked together in memory} to form a chain.

A linked list is a series of connected nodes, where each node is a data structure. A linked list can grow or shrink in size as the program runs. This is possible because the nodes in a linked list are dynamically allocated. If new data need to be added to a linked list, the program simply allocates another node and inserts it into the series. If a particular piece of data needs to be removed from the linked list, the program deletes the node containing that data.

\section*{Advantages of Linked Lists over Arrays and vectors}

Although linked lists are more complex to code and manage than arrays, they have some distinct advantages. First, a linked list can easily grow or shrink in size. In fact, the programmer doesn't need to know how many nodes will be in the list. They are simply created in memory as they are needed.

One might argue that linked lists are not superior to vectors (found in the Standard Template Library), because vectors, too, can expand or shrink. The advantage that linked lists have over vectors, however, is the speed at which a node may be inserted into or deleted from the list. To insert a value into the middle of a vector requires all the elements below the insertion point to be moved one position toward the vector's end, thus making room for the new value. Likewise, removing a value from a vector requires all the elements below the removal point to be moved one position toward the vector's beginning. When a node is inserted into or deleted from a linked list, none of the other nodes have to be moved.

\section*{The Composition of a Linked List}

Each node in a linked list contains one or more members that represent data. (Perhaps the nodes hold inventory records, or customer names, addresses, and telephone numbers.) In addition to the data, each node contains a pointer, which can point to another node. The makeup of a node is illustrated in Figure 18-1.

Figure 18-1 A node

A linked list is called "linked" because each node in the series has a pointer that points to the next node in the list. This creates a chain where the first node points to the second node, the second node points to the third node, and so on. This is illustrated in Figure 18-2.

Figure 18-2 Nodes linked by pointers

The list depicted in Figure 18-2 has three nodes, plus a pointer known as the list head. The head simply points to the first node in the list. Each node, in turn, points to the next node in the list. The first node points to the second node, which points to the third node. Because the third node is the last one in the list, it points to the null address (address 0 ). This is usually how the end of a linked list is signified-by letting the last node point to null.

NOTE: Figure 18-2 depicts the nodes in the linked list as being very close to each other, neatly arranged in a row. In reality, the nodes may be scattered around various parts of memory.

\section*{Declarations}

So how is a linked list created in C++? First you must declare a data structure that will be used for the nodes. For example, the following struct could be used to create a list where each node holds a double:
```

struct ListNode
{
double value;
ListNode *next;
};

```

The first member of the ListNode structure is a double named value. It will be used to hold the node's data. The second member is a pointer named next. The pointer can hold the address of any object that is a ListNode structure. This allows each ListNode structure to point to the next ListNode structure in the list.

Because the ListNode structure contains a pointer to an object of the same type as that being declared, it is known as a self-referential data structure. This structure makes it possible to create nodes that point to other nodes of the same type.

The next step is to define a pointer to serve as the list head, as shown here:
```

ListNode *head;

```

Before you use the head pointer in any linked list operations, you must be sure it is initialized to nullptr because that marks the end of the list. Once you have declared a node data structure and have created a null head pointer, you have an empty linked list. The next step is to implement operations with the list.

\section*{(1) Checkpoint}
18.1 Describe the two parts of a node.
18.2 What is a list head?
18.3 What signifies the end of a linked list?
18.4 What is a self-referential data structure?

\subsection*{18.2 Linked List Operations}

CONCEPT: The basic linked list operations are appending a node, traversing the list, inserting a node, deleting a node, and destroying the list.

In this section, we will develop an abstract data type that performs basic linked list operations using the ListNode structure and head pointer defined in the previous section. We will use the following class declaration, which is stored in NumberList.h.

\section*{Contents of NumberList.h}
```

// Specification file for the NumberList class
\#ifndef NUMBERLIST_H
\#define NUMBERLIST_H
class NumberList
{
private:
// Declare a structure for the list
struct ListNode
{
double value; // The value in this node
struct ListNode *next; // To point to the next node
};
ListNode *head; // List head pointer

```
```

public:
// Constructor
NumberList()
{ head = nullptr; }
// Destructor
~NumberList();
// Linked list operations
void appendNode(double);
void insertNode(double);
void deleteNode(double);
void displayList() const;
};
\#endif

```

Notice the constructor initializes the head pointer to nullptr. This establishes an empty linked list. The class has member functions for appending, inserting, and deleting nodes, as well as a displayList function that displays all the values stored in the list. The destructor destroys the list by deleting all its nodes. These functions are defined in NumberList.cpp. We will examine the member functions individually.

\section*{Appending a Node to the List}

To append a node to a linked list means to add the node to the end of the list. The appendNode member function accepts a double argument, num. The function will allocate a new ListNode structure, store the value in num in the node's value member, and append the node to the end of the list. Here is a pseudocode representation of the general algorithm:
```

Create a new node.
Store data in the new node.
If there are no nodes in the list
Make the new node the first node.
Else
Traverse the list to find the last node.
Add the new node to the end of the list.
End If.

```

Here is the actual \(\mathrm{C}++\) code for the function:
```

void NumberList::appendNode(double num)
{
13 ListNode *newNode; // To point to a new node
L4 ListNode *nodePtr; // To move through the list
16 // Allocate a new node and store num there.
17 newNode = new ListNode;
18 newNode->value = num;
19 newNode->next = nullptr;
21 // If there are no nodes in the list
22 // make newNode the first node.

```
15
20
```

    if (!head)
        head = newNode;
        else // Otherwise, insert newNode at end.
        {
        // Initialize nodePtr to head of list.
        nodePtr = head;
        // Find the last node in the list.
        while (nodePtr->next)
            nodePtr = nodePtr->next;
        // Insert newNode as the last node.
        nodePtr->next = newNode;
    }
    }

```

Let's examine the statements in detail. In lines 13 and 14, the function defines the following local variables:
```

ListNode *newNode; // To point to a new node
ListNode *nodePtr; // To move through the list

```

The newNode pointer will be used to allocate and point to the new node. The nodePtr pointer will be used to travel down the linked list, in search of the last node.

The following statements, in lines 17 through 19 , create a new node and store num in its value member:
```

newNode = new ListNode;
newNode->value = num;
newNode->next = nullptr;

```

The statement in line 19 is important. Because this node will become the last node in the list, its next pointer must be a null pointer.
In line 23 , we test the head pointer to determine whether there are any nodes already in the list. If head points to nullptr, we make the new node the first in the list. Making head point to the new node does this. Here is the code:
```

if (!head)
head = newNode;

```

If head does not point to nullptr, however, there are nodes in the list. The else part of the if statement must contain code to find the end of the list and insert the new node. The code, in lines 25 through 36, is shown here:
```

else
{
// Initialize nodePtr to head of list.
nodePtr = head;
// Find the last node in the list.
while (nodePtr->next)
nodePtr = nodePtr->next;
// Insert newNode as the last node.
nodePtr->next = newNode;
}

```

The code uses nodePtr to travel down the list. It does this by first assigning nodePtr to head in line 28.
```

nodePtr = head;

```

The while loop in lines 31 and 32 is then used to traverse (or travel through) the list searching for the last node. The last node will be the one whose next member points to nullptr.
```

while (nodePtr->next)
nodePtr = nodePtr->next;

```

When nodePtr points to the last node in the list, we make its next member point to newNode in line 35 with the following statement:
```

nodePtr->next = newNode;

```

This inserts newNode at the end of the list. (Remember, newNode->next already points to nul1ptr.)

Program 18-1 demonstrates the function.

\section*{Program 18-1}
```

// This program demonstrates a simple append
// operation on a linked list.
\#include <iostream>
\#include "NumberList.h"
using namespace std;
int main()
{
// Define a NumberList object.
NumberList list;
// Append some values to the list.
1ist.appendNode(2.5);
1ist.appendNode(7.9);
1ist.appendNode(12.6);
return 0;
}

```
(This program displays no output.)

Let's step through the program, observing how the appendNode function builds a linked list to store the three argument values used.

The head pointer is declared as a private member variable of the NumberList class. head is initialized to nu1 1 ptr by the NumberList constructor, which indicates that the list is empty.
The first call to appendNode in line 13 passes 2.5 as the argument. In the following statements, a new node is allocated in memory, 2.5 is copied into its value member, and nullptr is assigned to the node's next pointer:
```

newNode = new ListNode;
newNode->value = num;
newNode->next = nullptr;

```

Figure 18-3 illustrates the state of the head pointer and the new node.
Figure 18-3 State of the head pointer and the new node

The next statement to execute is the following if statement:
```

if (!head)
head = newNode;

```

Because head is a null pointer, the condition ! head is true. The statement head \(=\) newNode; is executed, making newNode the first node in the list. This is illustrated in Figure 18-4.

Figure 18-4 head points to newNode

There are no more statements to execute, so control returns to function main. In the second call to appendNode, in line \(14,7.9\) is passed as the argument. Once again, the first three statements in the function create a new node, store the argument in the node's value member, and assign its next pointer to nullptr. Figure 18-5 illustrates the current state of the list and the new node.

\section*{Figure 18-5 A new node is created}

newNode
head

Because head no longer points to nullptr, the else part of the if statement executes:
```

else // Otherwise, insert newNode at end.
{
// Initialize nodePtr to head of list.
nodePtr = head;
// Find the last node in the list.
while (nodePtr->next)
nodePtr = nodePtr->next;
// Insert newNode as the last node.
nodePtr->next = newNode;
}

```

The first statement in the else block assigns the value in head to nodePtr. This causes nodePtr to point to the same node that head points to. This is illustrated in Figure 18-6.

Figure 18-6 nodePtr points to the first node

Look at the next member of the node that nodePtr points to. It is a null pointer, which means that nodePtr->next is also a null pointer. nodePtr is already at the end of the list, so the while loop immediately terminates. The last statement, nodePtr \(\rightarrow\) next \(=\) newNode; causes nodePtr \(\rightarrow\) next to point to the new node. This inserts newNode at the end of the list as shown in Figure 18-7.

Figure 18-7 The new node is added to the list

The third time appendNode is called, in line \(15,12.6\) is passed as the argument. Once again, the first three statements create a node with the argument stored in the value member. This is shown in Figure 18-8.

Figure 18-8 A new node is created

Next, the else part of the if statement executes. As before, nodePtr is made to point to the same node as head, as shown in Figure 18-9.

Figure 18-9 nodePtr points to the first node

Because nodePtr->next is not a null pointer, the while loop will execute. After its first iteration, nodePtr will point to the second node in the list. This is shown in Figure 18-10.

Figure 18-10 nodePtr points to the second node

The while loop's conditional test will fail after the first iteration because nodePtr->next is now a null pointer. The last statement, nodePtr->next = newNode; causes nodePtr->next to point to the new node. This inserts newNode at the end of the list as shown in Figure 18-11.

Figure 18-11 The new node is added to the list

Figure 18-11 depicts the final state of the linked list.

\section*{Traversing a Linked List}

The appendNode function demonstrated in the previous section contains a while loop that traverses, or travels through the linked list. In this section, we will demonstrate the
displayList member function that traverses the list, displaying the value member of each node. The following pseudocode represents the algorithm:
```

Assign List head to node pointer.
While node pointer is not null
Display the value member of the node pointed to by node pointer.
Assign node pointer to its own next member.
End While.

```

The function is shown here:
```

void NumberList::displayList() const
{
ListNode *nodePtr; // To move through the list
// Position nodePtr at the head of the list.
nodePtr = head;
// While nodePtr points to a node, traverse
// the list.
while (nodePtr)
{
// Display the value in this node.
cout << nodePtr->value << endl;
// Move to the next node.
nodePtr = nodePtr->next;
}
}

```

Program 18-2, a modification of Program 18-1, demonstrates the function.

\section*{Program 18-2}
```

// This program demonstrates the displayList member function.
\#include <iostream>
\#include "NumberList.h"
using namespace std;
int main()
{
// Define a NumberList object.
NumberList list;
// Append some values to the list.
1ist.appendNode(2.5);
1ist.appendNode(7.9);
1ist.appendNode(12.6);
// Display the values in the list.
1ist.displayList();
return 0;
}

```

\section*{Program Output}
2.5
7.9
12.6

Usually, when an operation is to be performed on some or all the nodes in a linked list, a traversal algorithm is used. You will see variations of this algorithm throughout this chapter.

\section*{Inserting a Node}

Appending a node is a straightforward procedure. Inserting a node in the middle of a list, however, is more involved. For example, suppose the values in a list are sorted, and you wish all new values to be inserted in their proper position. This will preserve the order of the list. Using the ListNode structure again, the following pseudocode shows an algorithm for finding a new node's proper position in the list and inserting it there. The algorithm assumes the nodes in the list are already in order.
```

Create a new node.
Store data in the new node.
If there are no nodes in the list
Make the new node the first node.
Else
Find the first node whose value is greater than or equal to the new
value, or the end of the list (whichever is first).
Insert the new node before the found node, or at the end of the list
if no such node was found.
End If.

```

Notice the new algorithm finds the first node whose value is greater than or equal to the new value. The new node is then inserted before the found node. This will require the use of two node pointers during the traversal: one to point to the node being inspected, and another to point to the previous node. The code for the traversal algorithm is as follows. (As before, num holds the value being inserted into the list.)
```

// Position nodePtr at the head of list.
nodePtr = head;
// Initialize previousNode to nullptr.
previousNode = nullptr;
// Skip all nodes whose value is less than num.
while (nodePtr != nullptr \&\& nodePtr->value < num)
{
previousNode = nodePtr;
nodePtr = nodePtr->next;
}

```

This code segment uses the ListNode pointers nodePtr and previousNode. previousNode always points to the node before the one pointed to by nodePtr. The entire insertNode function is shown here:
```

void NumberList::insertNode(double num)
{
71 ListNode *newNode; // A new node
72 ListNode *nodePtr; // To traverse the list
73 ListNode *previousNode = nullptr; // The previous node
75 // Allocate a new node and store num there.
76 newNode = new ListNode;
77 newNode->value = num;
79 // If there are no nodes in the list
80 // make newNode the first node
81 if (!head)
83 head = newNode;
84 newNode->next = nullptr;
85 }
86 else // Otherwise, insert newNode
91 // Initialize previousNode to nullptr.
92 previousNode = nul1ptr;
94 // Skip all nodes whose value is less than num.
95 while (nodePtr != nullptr \&\& nodePtr->value < num)

```
74
78
82 \{
87
88
89
90

109
110
111
112
113
114 \}

Program 18-3 is a modification of Program 18-2. It uses the insertNode member function to insert a value in its ordered position in the list.

\section*{Program 18-3}
```

// This program demonstrates the insertNode member function.
\#include <iostream>
\#include "NumberList.h"
using namespace std;
int main()
{
// Define a NumberList object.
NumberList list;
// Build the list with some values.
1ist.appendNode(2.5);
1ist.appendNode(7.9);
1ist.appendNode(12.6);
// Insert a node in the middle of the list.
1ist.insertNode(10.5);
// Display the list
1ist.displayList();
return 0;
}

```

\section*{Program Output}
2.5
7.9
10.5
12.6

Like Program 18-2, Program 18-3 calls the appendNode function three times to build the list with the values \(2.5,7.9\), and 12.6. The insertNode function is then called, with the argument 10.5 .

In insertNode, a new node is created, and the function argument is copied to its value member. Because the list already has nodes stored in it, the el se part of the if statement will execute. It begins by assigning nodePtr to head. Figure 18-12 illustrates the state of the list at this point.

Figure 18-12 nodePtr points to the first node

Because nodePtr is not a null pointer and nodePtr->value is less than num, the while loop will iterate. During the iteration, previousNode will be made to point to the node that nodePtr is pointing to. nodePtr will then be advanced to point to the next node. This is shown in Figure 18-13.

Figure 18-13 previousNode points to the first node and nodePtr points to the second node

Once again, the loop performs its test. Because nodePtr is not a null pointer and nodePtr->value is less than num, the loop will iterate a second time. During the second iteration, both previousNode and nodePtr are advanced by one node in the list. This is shown in Figure 18-14.

Figure 18-14 previousNode points to the second node and nodePtr points to the third node

This time, the loop's test will fail because nodePtr->value is not less than num. The statements after the loop will execute, which cause previousNode->next to point to newNode, and newNode->next to point to nodePtr. This is illustrated in Figure 18-15.

This leaves the list in its final state. If you follow the links, from the head pointer to the null pointer, you will see the nodes are stored in the order of their value members.

Deleting a
Node from a Linked List

\section*{Checkpoint}
18.5 What is the difference between appending a node to a list and inserting a node into a list?
18.6 Which is easier to code, appending or inserting?
18.7 Why does the insertNode function shown in this section use a previousNode pointer?

\section*{Deleting a Node}

Deleting a node from a linked list requires two steps:
1. Remove the node from the list without breaking the links created by the next pointers.
2. Delete the node from memory.

The deleteNode member function searches for a node containing a particular value and deletes it from the list. It uses an algorithm similar to the insertNode function. Two node pointers, nodePtr and previousNode, are used to traverse the list. previousNode always points to the node whose position is just before the one pointed to by nodePtr. When nodePtr points to the node that is to be deleted, previousNode->next is made to point to nodePtr->next. This removes the node pointed to by nodePtr from the list. The final step performed by this function is to free the memory used by the node with the delete operator. The entire function is shown below:
```

1 2 2 void NumberList::deleteNode(double num)
123 {
124 ListNode *nodePtr; // To traverse the list
125 ListNode *previousNode; // To point to the previous node
126
127 // If the list is empty, do nothing.
128 if (!head)
1 2 9 ~ r e t u r n ;
1 3 0

```
```

131 // Determine if the first node is the one.
132 if (head->value == num)
133 {
134
135
nodePtr = head->next;
delete head;
head = nodePtr;
136
1 3 7
138
1 3 9
140
141
nodePtr = head;
142
143 // Skip all nodes whose value member is
144 // not equal to num.
145 while (nodePtr != nullptr \&\& nodePtr->value != num)
146 {
1 4 7 ~ p r e v i o u s N o d e ~ = ~ n o d e P t r ;
148
149
}
1 5 0
1 5 1
1 5 2
// If nodePtr is not at the end of the list,
// link the previous node to the node after
// nodePtr, then delete nodePtr.
if (nodePtr)
{
previousNode->next = nodePtr->next;
delete nodePtr;
}
}
}

```

Program 18-4 demonstrates the function by first building a list of three nodes, then deleting them one by one.

\section*{Program 18-4}
```

// This program demonstrates the deleteNode member function.
\#include <iostream>
\#include "NumberList.h"
using namespace std;
int main()
{
// Define a NumberList object.
NumberList list;
// Build the list with some values.
1ist.appendNode(2.5);
1ist.appendNode(7.9);
1ist.appendNode(12.6);

\section*{Program Output}

Here are the initial values:
2.5
7.9
12.6

Now deleting the node in the middle.
Here are the nodes left.
2.5
12.6

Now deleting the last node.
Here are the nodes left.
2.5

Now deleting the only remaining node.
Here are the nodes left.

To illustrate how deleteNode works, we will step through the first call, which deletes the node containing 7.9 as its value. This node is in the middle of the list.

In the deleteNode function, look at the else part of the second if statement. This is lines 138 through 159. This is where the function will perform its action since the list is not empty, and the first node does not contain the value 7.9. Just like insertNode, this function uses nodePtr and previousNode to traverse the list. The while loop in lines 145 through 149 terminates when the value 7.9 is located. At this point, the list and the other pointers will be in the state depicted in Figure 18-16.

Figure 18-16 previousNode points to the first node and nodePtr points to the second node

Next, the following statement in line 156 executes:
```

previousNode->next = nodePtr->next;

```

This statement causes the links in the list to bypass the node to which nodePtr points. Although the node still exists in memory, this removes it from the list, as illustrated in Figure 18-17.

Figure 18-17 Node removed from the list

The statement in line 157 uses the delete operator to complete the total deletion of the node.

\section*{Destroying the List}

It's important for the class's destructor to release all the memory used by the list. It does so by stepping through the list, deleting one node at a time. The code is shown here:
```

167 NumberList::~NumberList()
168 {
169 ListNode *nodePtr; // To traverse the list
170 ListNode *nextNode; // To point to the next node
1 7 1
172
1 7 3
174
175
1 7 6
1 7 7
178
1 7 9
180
181
182
183
1 8 4 ~ / / ~ P o s i t i o n ~ n o d e P t r ~ a t ~ t h e ~ n e x t ~ n o d e .
185 nodePtr = nextNode;
186
187

```

Notice the use of nextNode instead of previousNode. The nextNode pointer is used to hold the position of the next node in the list so it will be available after the node pointed to by nodePtr is deleted.

\section*{Checkpoint}
18.8 What are the two steps involved in deleting a node from a linked list?
18.9 When deleting a node, why can't you just use the delete operator to remove it from memory? Why must you take the steps you listed in response to Question 18.8?
18.10 In a program that uses several linked lists, what might eventually happen if the class destructor does not destroy its linked list?

\subsection*{18.3 A Linked List Template}

CONCEPT: A template can be easily created to store linked lists of any type.
The limitation of the NumberList class is that it can only hold double values. The class can easily be converted to a template that will accept any data type, as shown in the following code. (This file can be found in the Student Source Code Folder Chapter 18ULinkedList Template Version 1.)

\section*{Contents of LinkedList.h (Version 1)}
```

// A class template for holding a linked list.
\#ifndef LINKEDLIST_H
\#define LINKEDLIST_H
\#include <iostream> // For cout
using namespace std;

```
```

template <class T>
class LinkedList
{
private:
// Declare a structure for the list.
struct ListNode
{
T value; // The value in this node
struct ListNode *next; // To point to the next node
};
ListNode *head; // List head pointer
public:
// Constructor
NumberList()
{ head = nullptr; }
// Destructor
~NumberList();
// Linked list operations
void appendNode(T);
void insertNode(T);
void deleteNode(T);
void displayList() const;
};
//***************************************************
// appendNode appends a node containing the value *
// passed into newValue, to the end of the list.
//***************************************************
template <class T>
void LinkedList<T>::appendNode(T newValue)
{
ListNode *newNode; // To point to a new node
ListNode *nodePtr; // To move through the list
// Allocate a new node and store num there.
newNode = new ListNode;
newNode->value = num;
newNode->next = nullptr;
// If there are no nodes in the list
// make newNode the first node.
if (!head)
head = newNode;
else // Otherwise, insert newNode at end.
{
// Initialize nodePtr to head of list.
nodePtr = head;

```
```

            // Find the last node in the list.
            while (nodePtr->next)
            nodePtr = nodePtr->next;
            // Insert newNode as the last node.
            nodePtr->next = newNode;
        }
    }
//*****************************************************
// displayList shows the value
// stored in each node of the linked list
// pointed to by head.

            nodePtr = nodePtr->next;
        }
        // If the new node is to be the 1st in the list,
        // insert it before all other nodes.
        if (previousNode == nullptr)
        {
            head = newNode;
            newNode->next = nodePtr;
        }
        else // Otherwise insert after the previous node.
        {
            previousNode->next = newNode;
            newNode->next = nodePtr;
        }
    }
    }
//*******************************************************
// The deleteNode function searches for a node *
// with searchValue as its value. The node, if found,
// is deleted from the list and from memory.
||***********************************************************
template <class T>
{
ListNode *nodePtr; // To traverse the list
ListNode *previousNode; // To point to the previous node
// If the list is empty, do nothing.
if (!head)
return;
// Determine if the first node is the one.
if (head->value == num)

```
```

    {
        nodePtr = head->next;
        delete head;
        head = nodePtr;
        }
        else
        {
        // Initialize nodePtr to head of list.
        nodePtr = head;
        // Skip all nodes whose value member is
        // not equal to num.
        while (nodePtr != nullptr && nodePtr->value != num)
        {
            previousNode = nodePtr;
            nodePtr = nodePtr->next;
        }
        // If nodePtr is not at the end of the list,
        // link the previous node to the node after
        // nodePtr, then delete nodePtr.
        if (nodePtr)
        {
            previousNode->next = nodePtr->next;
            delete nodePtr;
        }
        }
    }
//***************************************************
// Destructor
// This function deletes every node in the list. *
//***************************************************
template <class T>
LinkedList<T>::~LinkedList()
{
ListNode *nodePtr; // To traverse the list
ListNode *nextNode; // To point to the next node
// Position nodePtr at the head of the list.
nodePtr = head;
// While nodePtr is not at the end of the list...
while (nodePtr != nullptr)
{
// Save a pointer to the next node.
nextNode = nodePtr->next;
// Delete the current node.
delete nodePtr;

```
```

219 // Position nodePtr at the next node.
220 nodePtr = nextNode;
221 }
222 }
223 \#endif

```

Note the template uses the \(==,!=\), and \(<\) relational operators to compare node values, and it uses the << operator with cout to display node values. Any type passed to the template must support these operators.

Now let's see how the template can be used to create a list of objects. Recall the Feet Inches class introduced in Chapter 14. That class overloaded numerous operators, including \(==\), <, and \(\ll\). In the Chapter 18 LinkedList Template Version 1 folder, we have included a modified version of the FeetInches class that also overloads the != operator. Program \(18-5\) is stored in that same folder. This program uses the LinkedList template to create a linked list of Feet Inches objects.

\section*{Program 18-5}
```

// This program demonstrates the linked 1ist template.

```
\#include <iostream>
\#include "LinkedList.h"
\#include "FeetInches.h"
using namespace std;
int main()
\{
    // Define a LinkedList object.
    LinkedList<FeetInches> 1ist;
    // Define some FeetInches objects.
    FeetInches distance1 \((5,4) ; / / 5\) feet 4 inches
    FeetInches distance2 \((6,8)\); // 6 feet 8 inches
    FeetInches distance3(8, 9); // 8 feet 9 inches
    // Store the FeetInches objects in the list.
    list.appendNode(distance1); // 5 feet 4 inches
    1ist.appendNode(distance2); // 6 feet 8 inches
    list.appendNode(distance3); // 8 feet 9 inches
    // Display the values in the list.
    cout << "Here are the initial values: \(\backslash n " ;\)
    1ist.displayList();
    cout << end1;
    // Insert another FeetInches object.
    cout << "Now inserting the value 7 feet 2 inches. 1 n ";
    FeetInches distance4(7, 2);
    1ist.insertNode(distance4) ;
    // Display the values in the list.
    cout << "Here are the nodes now. In";
    1ist.displayList();
    cout << endl;

43
44
45
46
\}

\section*{Program Output}

Here are the initial values:
5 feet, 4 inches
6 feet, 8 inches
8 feet, 9 inches

Now inserting the value 7 feet 2 inches.
Here are the nodes now.
5 feet, 4 inches
6 feet, 8 inches
7 feet, 2 inches
8 feet, 9 inches

Now deleting the last node.
Here are the nodes left.
5 feet, 4 inches
6 feet, 8 inches
7 feet, 2 inches

\section*{Using a Class Node Type}

In the LinkedList class template, the following structure was used to create a data type for the linked list node:
```

struct ListNode
{
T value;
struct ListNode *next;
};

```

Another approach is to use a separate class template to create a data type for the node. Then, the class constructor can be used to store an item in the value member and set the next pointer to nullptr. Here is an example:
```

template <class T>
class ListNode
{
public:
T value; // Node value
ListNode<T> *next; // Pointer to the next node

```
```

    // Constructor
    ListNode (T nodeValue)
    { value = nodeValue;
        next = nullptr; }
    };

```

The LinkedList class template can then be written as the following:
```

template <class T>
class LinkedList
{
private:
ListNode<T> *head; // List head pointer
public:
// Constructor
LinkedList()
{ head = nullptr; }
// Destructor
~LinkedList();
// Linked list operations
void appendNode(T);
void insertNode(T);
void deleteNode(T);
void displayList() const;
};

```

Because the ListNode class constructor assigns a value to the value member and sets the next pointer to nullptr, some of the code in the LinkedList class can be simplified. For example, the following code appears in the previous version of the LinkedList class template's appendNode function:
```

newNode = new ListNode;
newNode->value = newValue;
newNode->next = nullptr;

```

By using the ListNode class template with its constructor, these three lines of code can be reduced to one:
```

newNode = new ListNode<T>(newValue);

```
(This file can be found in the Student Source Code Folder Chapter 18\LinkedList Template Version 2.)

\subsection*{18.4 Variations of the Linked List}

CONCEPT: There are many ways to link dynamically allocated data structures together. Two variations of the linked list are the doubly linked list and the circular linked list.

The linked list examples we have discussed are considered singly linked lists. Each node is linked to a single other node. A variation of this is the doubly linked list. In this type of list, each node points not only to the next node, but also to the previous one. This is illustrated in Figure 18-18.

Figure 18-18 A doubly linked list

In Figure 18-18, the last node and the first node in the list have pointers to the null address. When the program traverses the list, it knows when it has reached either end.

Another variation is the circularly linked list. The last node in this type of list points to the first, as shown in Figure 18-19.

Figure 18-19 A circularly linked list

\subsection*{18.5 The STL 1 ist and forward_1ist Containers \\ CONCEPT: The Standard Template Library provides two containers that are implemented as linked lists. The list container is a doubly linked list, and the forward_1ist container is a singly linked list.}

The list container, found in the Standard Template Library, is implemented as a doubly linked list, and the forward_1ist container is implemented as a singly linked list. These containers can perform insertion and emplacement operations quicker than vectors because linked lists do not have to shift their existing elements in memory when a new element is added. The list and forward_1ist containers are also efficient at adding elements at their back because they have a built-in pointer to the last element in the list (no traversal required).

A disadvantage of the list and forward_1ist containers, compared to other sequence containers, is that you cannot use an index to access a list element. If you want to access an element that is in the middle of a list or forward_1ist, you have to step through each element until you reach the one you are looking for.

\section*{The 1 ist Container}

To use the list class, you need to \#include the <list> header file in your program. Then, you can define a list object using one of the four list constructors. Table 18-1 shows the general format of a 1 ist definition statement using each constructor. Table 18-2 lists many (but not all) of the list class's member functions.

\section*{Table 18-1 1 ist Definition Statements}

\section*{Default Constructor list<dataType> name;}

Creates an empty list object. In the general format, dataType is the data type of each element, and name is the name of the list.
Fill Constructor list<dataType> name(size);
Creates a list object of a specified size. In the general format, dataType is the data type of each element, and name is the name of the list. The size argument is an unsigned integer that specifies the number of elements that the list should initially have. If the elements are objects, they are initialized via their default constructors. Otherwise, the elements are initialized with the value 0 .
Fill Constructor list<dataType> name(size, value);
Creates a list object of a specified size, where each element is initially given a specified value. In the general format, dataType is the data type of each element, and name is the name of the list. The size argument is an unsigned integer that specifies the number of elements that the list should initially have, and the value argument is the value to fill each element with.

Table 18-1 (continued)
\begin{tabular}{|c|c|}
\hline \multirow[t]{2}{*}{Range Constructor} & 1ist<dataType> name(iterator1, iterator2); \\
\hline & Creates a list object that initially contains a range of values specified by two iterators. In the general format, dataType is the data type of each element, and name is the name of the list. The iterator 1 and iterator2 arguments mark the beginning and end of a range of values that will be stored in the list. \\
\hline \multirow[t]{2}{*}{Copy Constructor} & 1ist<dataType> name(1ist2); \\
\hline & Creates a list object that is a copy of another list object. In the general format, dataType is the data type of each element, name is the name of the 1ist, and 1ist2 is the 1ist to copy. \\
\hline
\end{tabular}

Table 18-2 Many of the 1 ist Member Functions
\begin{tabular}{|c|c|}
\hline Member Function & Description \\
\hline back() & Returns a reference to the last element in the container. \\
\hline begin() & Returns an iterator to the first element in the container. \\
\hline cbegin() & Returns a const_iterator to the first element in the container. \\
\hline cend () & Returns a const_iterator pointing to the end of the container. \\
\hline clear () & Erases all of the elements in the container. \\
\hline crbegin() & Returns a const_reverse_iterator pointing to the last element in the container. \\
\hline crend () & Returns a const_reverse_iterator pointing to the first element in the container. \\
\hline emplace(it, args...) & Constructs a new object as an element, passing args . . . as arguments to the element's constructor. The it argument is an iterator pointing to an existing element in the container. The new element will be inserted before the one pointed to by it. \\
\hline emplace_back(args...) & Constructs a new object as an element at the end of the container. The args... arguments are passed to the element's constructor. \\
\hline emplace_front(args...) & Constructs a new object as an element at the front of the container. The args... arguments are passed to the element's constructor. \\
\hline empty () & Returns true if the container is empty, or false otherwise. \\
\hline end () & Returns an iterator pointing to the end of the container. \\
\hline erase(it) & Erases the element pointed to by the iterator it. This function returns an iterator pointing to the element that follows the removed element (or the end of the container, if the removed element was the last one). \\
\hline erase(iterator1, iterator2) & Erases a range of elements. The iterator1 and iterator2 arguments mark the beginning and end of a range of values that will be erased. This function returns an iterator pointing to the element that follows the removed elements (or the end of the container, if the last element was erased). \\
\hline
\end{tabular}

Table 18-2 (continued)
\begin{tabular}{|c|c|}
\hline Member Function & Description \\
\hline front() & Returns a reference to the first element in the container. \\
\hline insert(it, value) & Inserts a new element with value as its value. The it argument is an iterator pointing to an existing element in the container. The new element will be inserted before the one pointed to by it. The function returns an iterator pointing to the newly inserted element. \\
\hline insert(it, \(n\), value) & Inserts \(n\) new elements with value as their value. The \(i t\) argument is an iterator pointing to an existing element in the container, and \(n\) is an unsigned integer. The new elements will be inserted before the one pointed to by \(i t\). The function returns an iterator pointing to the first element of the newly inserted elements. \\
\hline \begin{tabular}{l}
insert(iterator1, \\
iterator2, \\
iterator3)
\end{tabular} & Inserts a range of new elements. The iterator1 argument points to an existing element in the container. The range of new elements will be inserted before the element pointed to by iterator1. The iterator 2 and iterator3 arguments mark the beginning and end of a range of values that will be inserted. (The element pointed to by iterator 3 will not be included in the range.) The function returns an iterator pointing to the first element of the newly inserted range. \\
\hline max_size() & Returns the theoretical maximum size of the container. \\
\hline merge (second) & The second argument must be a list object of the same type as the calling object. The elements of both the calling 1 ist object and the second list object must be sorted prior to calling the merge member function. The function merges the contents of the calling object and the second object. The elements of the second object will be inserted at their ordered positions. After the function executes, the second list object will be empty. \\
\hline pop_back() & Removes the last element of the container. \\
\hline pop_front() & Removes the first element of the container. \\
\hline push_back(value) & Adds a new element containing value to the end of the container. \\
\hline push_front (value) & Adds a new element containing value to the beginning of the container. \\
\hline rbegin() & Returns a reverse_iterator pointing to the last element in the container. \\
\hline remove(value) & Removes all elements with a value equal to value. \\
\hline remove_if(function) & function is a unary predicate function (a function or function object that accepts one argument, and returns a Boolean value). This member function passes each element as an argument to function, and removes all elements that cause the function to return true. \\
\hline rend () & Returns a reverse_iterator pointing to the first element in the container. \\
\hline
\end{tabular}

Table 18-2 (continued)
\begin{tabular}{|c|c|}
\hline Member Function & Description \\
\hline resize( \(n\) ) & The \(n\) argument is an unsigned integer. This function resizes the container so it has \(n\) elements. If the current size of the container is larger than \(n\), then the container is reduced in size so it keeps only the first \(n\) elements. If the current size of the container is smaller than \(n\), then the container is increased in size so it has \(n\) elements. \\
\hline resize( \(n\), value) & Resizes the container so that it has \(n\) elements (the \(n\) argument is an unsigned integer). If the current size of the container is larger than \(n\), then the container is reduced in size so it keeps only the first \(n\) elements. If the current size of the container is smaller than \(n\), then the container is increased in size so it has \(n\) elements, and each of the new elements is initialized with value. \\
\hline reverse() & Reverses the order of the elements in the container. \\
\hline size() & Returns the number of elements in the container. \\
\hline sort() & Sorts the elements in ascending order. Uses the < operator to compare elements. \\
\hline swap (second) & The second argument must be a list object of the same type as the calling object. The function swaps the contents of the calling object and the second object. \\
\hline unique() & If the container has any consecutive elements that are duplicates, all are removed except the first one. \\
\hline
\end{tabular}

Program 18-6 demonstrates some simple operations with the 1 ist container.

\section*{Program 18-6}
```

// This program demonstrates the STL list container.
\#include <iostream>
\#include <list>
using namespace std;
int main()
{
// Define an empty list.
list<int> myList;
// Add some values to the list.
for (int x = 0; x < 100; x += 10)
myList.push_back(x);
// Use an iterator to display the values.
for (auto it = myList.begin(); it != myList.end(); it++)
cout << *it << " ";
cout << endl;

```

\section*{Program 18-6 (continued)}

20 // Now reverse the order of the elements.
21 myList.reverse();
    // Display the values again, with a range-based for loop
    for (auto element : myList)
        cout << element << " ";
    cout << end1;
    return 0 ;
\}

\section*{Program Output}
\(\begin{array}{lllllllll}0 & 10 & 20 & 30 & 40 & 50 & 60 & 70 & 80 \\ 90\end{array}\)
\(90 \quad 80 \quad 70 \quad 60 \quad 5040 \quad 30 \quad 20 \quad 10 \quad 0\)

\section*{The forward_1ist Container}

Because a forward_list is implemented as a singly linked list, each node keeps only one pointer: a pointer to the next node. Compared to a list container, which keeps two pointers per node (one to the next node, and one to the previous node), a forward_list uses less memory than a list. However, you can step only forward through a forward_list. If you need to move both forward and backward, you will need to use a list container.

The forward_1ist container provides most of the same member functions as the list container, with a few exceptions. You can find documentation for the forward_list container with a good online reference site, such as www.cppreference.com or www.cplusplus.com.

\section*{Review Questions and Exercises}

\section*{Short Answer}
1. What are some of the advantages that linked lists have over arrays?
2. What advantage does a linked list have over the STL vector?
3. What is a list head?
4. What is a self-referential data structure?
5. How is the end of a linked list usually signified?
6. Name five basic linked list operations.
7. What is the difference between appending a node and inserting a node?
8. When is it necessary to destroy a linked list and why?
9. What are the two steps required to delete a node from a linked list?
10. What is the advantage of using a template to implement a linked list?
11. State the difference between the structure of a node of a singly linked list and a doubly linked list.
12. What type of linked list is the STL list container? What type of linked list is the STL forward_list container?

\section*{Fill-in-the-Blank}
13. The two parts of a node in a linked list are \(\qquad\) and \(\qquad\) .
14. A data structure that points to an object of the same type as itself is known as a(n)
\(\qquad\) data structure.
15. After creating a linked list's head pointer, you should make sure it points to
\(\qquad\) before using it in any operations.
16. \(\qquad\) a node means adding it to the end of a list.
17. \(\qquad\) a node means adding it to a list, but not necessarily to the end.
18. \(\qquad\) a list means traveling through the list.
19. In \(\mathrm{a}(\mathrm{n})\) \(\qquad\) list, the last node has a pointer to the first node.
20. Each node of a doubly linked list has \(\qquad\) node pointer(s).

\section*{Algorithm Workbench}
21. Consider the following code:
```

struct ListNode
{
int value;
struct ListNode *next;
};
ListNode *head; // List head pointer

```

Assume a linked list has been created and head points to the first node. Write code that traverses the list displaying the contents of each node's value member.
22. Write code that destroys the linked list described in Question 21.
23. Write code that defines an STL 1ist container for holding float values.
24. Write code that stores the values \(12.7,9.65,8.72\), and 4.69 in the 1 ist container you defined for Question 23.
25. Write code that reverses the order of the items you stored in the list container in Question 24.

\section*{True or False}
26. T F The programmer must know in advance how many nodes will be needed in a linked list.
27. T F It is not necessary for each node in a linked list to have a self-referential pointer.
28. T F A node of a linked list should contain only one data element.
29. T F Appending a node to a list is same as inserting a node to a list.
30. T F An STL list container is a template version of a doubly linked list.
31. T F When a singly linked list is being traversed, and the current node pointer is in any interior node, it is not possible to retrace back to the list head.
32. T F A doubly linked list can be traversed in both directions.

\section*{Find the Errors}

Each of the following member functions has errors in the way it performs a linked list operation. Find as many mistakes as you can.
33. // Insert a node at the beginning of a linked list
```

void NumberList::addInFront(double num)

```
\{
    ListNode *newNode;
    // Allocate a new node \& store num
    newNode = new listNode;
    newNode->value \(=\) num;
    // If there are no nodes in the list
    // make newNode the first node.
    if (!head)
            head \(=\) newNode;
    // Otherwise, insert newNode before head.
    else
    \{
        newNode->next = head->next;
            // Assign newNode as the list head
            head \(=\) newNode;
    \}
\}
34. void NumberList::deleteNode(double num)
    \{
        ListNode *nodePtr, *previousNode;
        // If the list is empty, do nothing.
        if (!head)
            return;
        // Determine if the first node is the one.
    if (head->value == num)
        delete head;
    else
    \{
        // Initialize nodePtr to head of list.
        nodePtr = head;
        // Skip all nodes whose value member is
        // not equal to num.
        while (nodePtr->value != num)
        \{
                previousNode = nodePtr;
                nodePtr \(=\) nodePtr->next;
        \}
```

        // Link the previous node to the node after
        // nodePtr, then delete nodePtr.
        previousNode->next = nodePtr->next;
        delete nodePtr;
    }
    }
35. NumberList::~NumberList()
{
ListNode *nodePtr, *nextNode;
nodePtr = head;
while (nodePtr != nullptr)
{
nextNode = nodePtr->next;
nodePtr->next = nullptr;
nodePtr = nextNode;
}
}

```

\section*{Programming Challenges}

\section*{1. Your Own Linked List}

Design your own linked list class to hold a series of integers. The class should have member functions for appending, inserting, and deleting nodes. Don't forget to add a destructor that destroys the list. Demonstrate the class with a driver program.

\section*{2. List Print}

Modify the linked list class you created in Programming Challenge 1 to add a print member function. The function should display all the values in the linked list. Test the class by starting with an empty list, adding some elements, then printing the resulting list out.

\section*{3. List Copy Constructor}

Modify your linked list class of Programming Challenges 1 and 2 to add a copy constructor. Test your class by making a list, making a copy of the list, then displaying the values in the copy.

\section*{4. List Reverse}

Modify the linked list class you created in the previous programming challenges by adding a member function named reverse that rearranges the nodes in the list so their order is reversed. Demonstrate the function in a simple driver program.

\section*{5. List Search}

Modify the linked list class you created in the previous programming challenges to include a member function named search that returns the position of a specific value, x , in the linked list. The first node in the list is at position 0 , the second node is at position 1 , and so on. If \(x\) is not found on the list, the search should return -1 . Test the new member function using an appropriate driver program.

VideoNote
Solving the Member Insertion by Position Problem

\section*{6. Member Insertion by Position}

Modify the list class you created in the previous programming challenges by adding a member function for inserting a new item at a specified position. A position of 0 means that the value will become the first item on the list, a position of 1 means the value will become the second item on the list, and so on. A position equal to or greater than the length of the list means the value is placed at the end of the list.

\section*{7. Member Removal by Position}

Modify the list class you created in the previous programming challenges by adding a member function for deleting a node at a specified position. A value of 0 for the position means the first node in the list (the current head) is deleted. The function does nothing if the specified position is greater than or equal to the length of the list.

\section*{8. Doubly Linked List}

Design a class template DoubleList to implement a doubly linked list. Include member functions to append a node at the end of the list and display the list.

\section*{9. Rainfall Statistics Modification}

Modify Programming Challenge 2 in Chapter 7 (Rainfall Statistics) to let the user decide how many months of data will be entered. Use a linked list instead of an array to hold the monthly data.

\section*{10. Payroll Modification}

Modify Programming Challenge 9 in Chapter 7 (Payroll) to use three linked lists instead of three arrays to hold the employee IDs, hours worked, and wages. When the program starts, it should ask the user to enter the employee IDs. There should be no limit on the number of IDs the user can enter.

\section*{11. Priority Linked List}

In a priority linked list, each node has a priority value in addition to data value. Nodes are arranged in order of diminishing priority. A lower value implies higher priority. Nodes of equal priority are arranged in order of their insertion.
Design a PriorityList class. The class should have member functions to add a node to the list and to display the priority linked list. Demonstrate the class in a program.

\section*{12. Double Merge}

Modify the NumberList class shown in this chapter to include a member function named mergeArray. The mergeArray function should take an array of doubles as its first argument, and an integer as its second argument. (The second argument will specify the size of the array being passed into the first argument.)
The function should merge the values in the array into the linked list. The value in each element of the array should be inserted (not appended) into the linked list. When the values are inserted, they should be in numerical order. Demonstrate the function with a driver program. When you are satisfied with the function, incorporate it into the LinkedList template.

\section*{13. Rainfall Statistics Modification \#2}

Modify the program you wrote for Programming Challenge 9 so it saves the data in the linked list to a file. Write a second program that reads the data from the file into a linked list and displays it on the screen.

\section*{14. Overloaded [] Operator}

Modify the linked list class you created in Programming Challenge 1 (or the LinkedList template presented in this chapter) by adding an overloaded [] operator function. This will give the linked list the ability to access nodes using a subscript, like an array. The subscript 0 will reference the first node in the list, the subscript 1 will reference the second node in the list, and so forth. The subscript of the last node will be the number of nodes minus 1 . If an invalid subscript is used, the function should throw an exception.
15. pop and push Member Functions

The STL 1 ist container has member functions named pop_back, pop_front, push_back, and push_front, as described in Table 18-2. Modify the linked list class you created in Programming Challenge 1 (or the LinkedList template presented in this chapter) by adding your own versions of these member functions.

\section*{9 Stacks and Queues}

TOPICS
19.1 Introduction to the Stack ADT
19.2 Dynamic Stacks
19.3 The STL stack Container
19.4 Introduction to the Queue ADT
19.5 Dynamic Queues
19.6 The STL deque and queue Containers

\subsection*{19.1 Introduction to the Stack ADT}

CONCEPT: A stack is a data structure that stores and retrieves items in a last-in, first-out manner.

\section*{Definition}

Like an array or a linked list, a stack is a data structure that holds a sequence of elements. Unlike arrays and lists, however, stacks are last-in, first-out (LIFO) structures. This means when a program retrieves elements from a stack, the last element inserted into the stack is the first one retrieved (and likewise, the first element inserted is the last one retrieved).

When visualizing the way a stack works, think of a stack of plates at the beginning of a cafeteria line. When a cafeteria worker replenishes the supply of plates, the first one he or she puts on the stack is the last one taken off. This is illustrated in Figure 19-1.

Figure 19-1 A stack of plates

The LIFO characteristic of a stack of plates in a cafeteria is also the primary characteristic of a stack data structure. The last data element placed on the stack is the first data retrieved from the stack.

\section*{Applications of Stacks}

Stacks are useful data structures for algorithms that work first with the last saved element of a series. For example, computer systems use stacks while executing programs. When a function is called, they save the program's return address on a stack. They also create local variables on a stack. When the function terminates, the local variables are removed from the stack and the return address is retrieved. Also, some calculators use a stack for performing mathematical operations.

\section*{Static and Dynamic Stacks}

There are two types of stack data structures: static and dynamic. Static stacks have a fixed size and are implemented as arrays. Dynamic stacks grow in size as needed and are implemented as linked lists. In this section, you will see examples of both static and dynamic stacks.

\section*{Stack Operations}

A stack has two primary operations: push and pop. The push operation causes a value to be stored, or pushed onto the stack. For example, suppose we have an empty integer stack that is capable of holding a maximum of three values. With that stack, we execute the following push operations.
```

push(5);
push(10);
push(15);

```

Figure 19-2 illustrates the state of the stack after each of these push operations.
Figure 19-2 State of the stack

The pop operation retrieves (and hence, removes) a value from the stack. Suppose, we execute three consecutive pop operations on the stack shown in Figure 19-2. Figure 19-3 depicts the results.

Figure 19-3 State of the stack

As you can see from Figure 19-3, the last pop operation leaves the stack empty.
For a static stack (one with a fixed size), we will need a Boolean isFull operation. The isFull operation returns true if the stack is full, and false otherwise. This operation is necessary to prevent a stack overflow in the event a push operation is attempted when all the stack's elements have values stored in them.

For both static and dynamic stacks, we will need a Boolean isEmpty operation. The isEmpty operation returns true when the stack is empty, and false otherwise. This prevents an error from occurring when a pop operation is attempted on an empty stack.

\section*{A Static Stack Class}

Now we examine a class, IntStack, that stores a static stack of integers and performs the isFull and isEmpty operations. The class has the member variables described in Table 19-1.

Table 19-1 The IntStack Class's Member Variables
\begin{tabular}{ll}
\hline Member Variable & Description \\
\hline stackArray & \begin{tabular}{l} 
A pointer to int. When the constructor is executed, it uses stackArray \\
to dynamically allocate an array for storage.
\end{tabular} \\
stackSize & \begin{tabular}{l} 
An integer that holds the size of the stack.
\end{tabular} \\
top & An integer that is used to mark the top of the stack. \\
\hline
\end{tabular}

The class's member functions are listed in Table 19-2.
Table 19-2 The IntStack Class's Member Functions
\begin{tabular}{ll}
\hline Member Functions & Description \\
\hline Constructor & \begin{tabular}{l} 
The class constructor accepts an integer argument that specifies the size \\
of the stack. An integer array of this size is dynamically allocated and \\
assigned to stackArray. Also, the variable top is initialized to -1.
\end{tabular} \\
Destructor & \begin{tabular}{l} 
The destructor frees the memory that was allocated by the constructor. \\
isFulı \\
Returns true if the stack is full, and fal se otherwise. The stack is full \\
when top is equal to stackSize -1.
\end{tabular} \\
pop & \begin{tabular}{l} 
Returns true if the stack is empty, and false otherwise. The stack is \\
empty when top is set to -1.
\end{tabular} \\
push & \begin{tabular}{l} 
The pop function uses an integer reference parameter. The value at the \\
top of the stack is removed and copied into the reference parameter. \\
The push function accepts an integer argument, which is pushed onto the \\
top of the stack.
\end{tabular} \\
\hline
\end{tabular}

NOTE: Even though the constructor dynamically allocates the stack array, it is still a static stack. The size of the stack does not change once it is allocated.

The code for the class is as follows:

\section*{Contents of IntStack.h}
```

// Specification file for the IntStack class
\#ifndef INTSTACK_H
\#define INTSTACK_H
class IntStack
{
private:
int *stackArray; // Pointer to the stack array
int stackSize; // The stack size
int top; // Indicates the top of the stack
public:
// Constructor
IntStack(int);
// Copy constructor
IntStack(const IntStack \&);
// Destructor
~IntStack();
// Stack operations
void push(int);
void pop(int \&);
bool isFul1() const;
bool isEmpty() const;
};
\#endif

```

\section*{Contents of IntStack.cpp}
```

// Implementation file for the IntStack class
\#include <iostream>
\#include "IntStack.h"
using namespace std;
//**************************************************
// Constructor
// This constructor creates an empty stack. The *
// size parameter is the size of the stack.
//****************************************************
IntStack::IntStack(int size)
{
stackArray = new int[size];
stackSize = size;
top = -1;
}

```
```

//***********************************************
// Copy constructor
//************************************************
IntStack::IntStack(const IntStack \&obj)
{
// Create the stack array.
if (obj.stackSize > 0)
stackArray = new int[obj.stackSize];
else
stackArray = nullptr;
// Copy the stackSize attribute.
stackSize = obj.stackSize;
// Copy the stack contents.
for (int count = 0; count < stackSize; count++)
stackArray[count] = obj.stackArray[count];
// Set the top of the stack.
top = obj.top;
}
//************************************************
// Destructor
//***********************************************
IntStack::~IntStack()
{
delete [] stackArray;
}
//**************************************************
// Member function push pushes the argument onto *
// the stack.
/|***************************************************
void IntStack::push(int num)
{
if (isFull())
{
cout << "The stack is full.\n";
}
else
{
top++;
stackArray[top] = num;
}
}

```
```

/|******************************************************
// Member function pop pops the value at the top *
// of the stack off, and copies it into the variable *
// passed as an argument.
/l******************************************************
void IntStack::pop(int \&num)
{
if (isEmpty())
{
cout << "The stack is empty.\n";
}
else
{
num = stackArray[top];
top--;
}
}
//***************************************************
// Member function isFull returns true if the stack *
// is full, or false otherwise.
|/|******************************************************
bool IntStack::isFul1() const
{
bool status;
if (top == stackSize - 1)
status = true;
else
status = false;
return status;
}
//******************************************************
// Member function isEmpty returns true if the stack *
// is empty, or false otherwise.
/|******************************************************
boo1 IntStack::isEmpty() const
{
bool status;
if (top == -1)
status = true;
else
status = false;
return status;
}

```

The class has two constructors, one that accepts an argument for the stack size (lines 12 through 17 of IntStack.cpp), and a copy constructor (lines 23 through 40). The first constructor dynamically allocates the stack array in line 14, initializes the stackSize member variable in line 15 , and initializes the top member variable in line 16 . Remember items are stored to and retrieved from the top of the stack. In this class, the top of the stack is actually the end of the array. The variable top is used to mark the top of the stack by holding the subscript of the last element. When top holds -1 , it indicates the stack is empty. (See the isEmpty function, which returns true if top is -1 , or false otherwise.) The stack is full when top is at the maximum subscript, which is stackSize - 1. This is the value for which isFull tests. It returns true if the stack is full, or false otherwise.

Program 19-1 is a simple driver that demonstrates the IntStack class.

\section*{Program 19-1}
```

// This program demonstrates the IntStack class.
\#include <iostream>
\#include "IntStack.h"
using namespace std;
int main()
{
int catchVar; // To hold values popped off the stack
// Define a stack object to hold 5 values.
IntStack stack(5);
// Push the values 5, 10, 15, 20, and 25 onto the stack.
cout << "Pushing 5\n";
stack.push(5);
cout << "Pushing 10\n";
stack.push(10);
cout << "Pushing 15\n";
stack.push(15);
cout << "Pushing 20\n";
stack.push(20);
cout << "Pushing 25\n";
stack.push(25);
// Pop the values off the stack.
cout << "Popping...\n";
stack.pop(catchVar);
cout << catchVar << endl;
stack.pop(catchVar);
cout << catchVar << endl;
stack.pop(catchVar);
cout << catchVar << endl;
stack.pop(catchVar);
cout << catchVar << endl;
stack.pop(catchVar);
cout << catchVar << endl;
return 0;
}

```
```

Program 19-1
(continued)
Program Output
Pushing 5
Pushing 10
Pushing 15
Pushing 20
Pushing 25
Popping...
25
20
15
10
5

```

In Program 19-1, the constructor is called with the argument 5 . This sets up the member variables as shown in Figure 19-4. Because top is set to -1, the stack is empty.

Figure 19-4 State of the stack

Figure 19-5 shows the state of the member variables after the push function is called the first time (with 5 as its argument). The top of the stack is now at element 0 .

Figure 19-5 State of the stack

Figure 19-6 shows the state of the member variables after all five calls to the push function. Now, the top of the stack is at element 4 , and the stack is full.

Figure 19-6 State of the stack

Notice the pop function uses a reference parameter, num. The value that is popped off the stack is copied into num so it can be used later in the program. Figure 19-7 depicts the state of the class members, and the num parameter, just after the first value is popped off the stack.

Figure 19-7 State of the stack

The program continues to call the pop function until all the values have been retrieved from the stack.

\section*{Implementing Other Stack Operations}

More complex operations may be built on the basic stack class previously shown. In this section, we will discuss a class, MathStack, that is derived from IntStack. The MathStack class has two member functions: add () and sub(). The add () function pops the first two values off the stack, adds them together, then pushes the sum onto the stack. The sub() function pops the first two values off the stack, subtracts the second value from the first, then pushes the difference onto the stack. The class declaration is as follows:

\section*{Contents of MathStack.h}
```

// Specification file for the MathStack class
\#ifndef MATHSTACK_H
\#define MATHSTACK_H
\#include "IntStack.h"
class MathStack : public IntStack
{
public:
// Constructor
MathStack(int s) : IntStack(s) {}
// MathStack operations
void add();
void sub();
};
\#endif

```

The definitions of the member functions are shown here:

\section*{Contents of MathStack. cpp}
```

1 // Implementation file for the MathStack class
2 \#include "MathStack.h"
3

```
```

//*************************************************
// Member function add. add pops *
// the first two values off the stack and *
// adds them. The sum is pushed onto the stack.
/|***************************************************
void MathStack::add()
{
int num, sum;
// Pop the first two values off the stack.
pop(sum);
pop(num);
// Add the two values, store in sum.
sum += num;
// Push sum back onto the stack.
push(sum);
}
//*************************************************
// Member function sub. sub pops the
// first two values off the stack. The *
// second value is subtracted from the *
// first value. The difference is pushed *
// onto the stack. *
//**************************************************
void MathStack::sub()
{
int num, diff;
// Pop the first two values off the stack.
pop(diff);
pop(num);
// Subtract num from diff.
diff -= num;
// Push diff back onto the stack.
push(diff);
}

```

The class is demonstrated in Program 19-2, a simple driver.

\section*{Program 19-2}
```

// This program demonstrates the MathStack class.
\#include <iostream>
\#include "MathStack.h"
using namespace std;

```
5
```

int main()
{
int catchVar; // To hold values popped off the stack
// Create a MathStack object.
MathStack stack(5);
// Push 3 and 6 onto the stack.
cout << "Pushing 3\n";
stack.push(3);
cout << "Pushing 6\n";
stack.push(6);
// Add the two values.
stack.add();
// Pop the sum off the stack and display it.
cout << "The sum is ";
stack.pop(catchVar);
cout << catchVar << endl << endl;
// Push 7 and 10 onto the stack
cout << "Pushing 7\n";
stack.push(7);
cout << "Pushing 10\n";
stack.push(10);
// Subtract 7 from 10.
stack.sub();
// Pop the difference off the stack and display it.
cout << "The difference is ";
stack.pop(catchVar);
cout << catchVar << endl;
return 0;
}

```

\section*{Program Output}

Pushing 3
Pushing 6
The sum is 9
Pushing 7
Pushing 10
The difference is 3

It will be left as a Programming Challenge for you to implement the mult(), div(), and \(\bmod ()\) functions that will complete the MathStack class.

\section*{A Static Stack Template}

The stack classes shown previously in this chapter work only with integers. A stack template can be easily designed to work with any data type, as shown by the following example:

\section*{Contents of Stack.h}
```

\#ifndef STACK_H
\#define STACK_H
\#include <iostream>
using namespace std;
// Stack template
template <class T>
class Stack
{
private:
T *stackArray;
int stackSize;
int top;
public:
// Constructor
Stack(int);
// Copy constructor
Stack(const Stack\&);
// Destructor
~Stack();
// Stack operations
void push(T);
void pop(T \&);
bool isFull();
bool isEmpty();
};
//****************************************************
/| Constructor *
/|*****************************************************
template <class T>
Stack<T>::Stack(int size)
{
stackArray = new T[size];
stackSize = size;
top = -1;
}
/|******************************************************
// Copy constructor
//****************************************************

```
47
```

template <class T>
Stack<T>::Stack(const Stack \&obj)
{
// Create the stack array.
if (obj.stackSize > 0)
stackArray = new T[obj.stackSize];
e1se
stackArray = nullptr;
// Copy the stackSize attribute.
stackSize = obj.stackSize;
// Copy the stack contents.
for (int count = 0; count < stackSize; count++)
stackArray[count] = obj.stackArray[count];
// Set the top of the stack.
top = obj.top;
}
/|****************************************************
// Destructor
//****************************************************
template <class T>
Stack<T>: :~Stack()
{
if (stackSize > 0)
delete [] stackArray;
}
/|*************************************************************
// Member function push pushes the argument onto
// the stack.
|/******************************************************************
template <class T>
void Stack<T>::push(T item)
{
if (isFul1())
{
cout << "The stack is full.\n";
}
else
{
top++;
stackArray[top] = item;
}
}
/|**************************************************************
// Member function pop pops the value at the top
// of the stack off, and copies it into the variable
// passed as an argument.
//*

```

105
106
107
108
109
110
111
112
113
114
115
template <class T>
void Stack<T>: pop(T \&item)
\{
    if (isEmpty())
    \{
    \}
    else
    \{
        top--;
    \}
\}
template <class T>
bool Stack<T>::isFul1()
\{
    bool status;
            status = true;
        else
        return status;
\}
template <class T>
bool Stack<T>::isEmpty()
\{
    bool status;
    if (top == -1)
        status = true;
        else
        return status;
\}
\#endif
            cout << "The stack is empty. 1 n ";
        item = stackArray[top];

// is full, or false otherwise.

    if (top == stackSize - 1)
            status = false;

// Member function isEmpty returns true if the stack
// is empty, or false otherwise.

            status = false;

Program 19-3 demonstrates the Stack template. It creates a stack of strings, then presents a menu that allows the user to push an item onto the stack, pop an item from the stack, or quit the program.

\section*{Program 19-3}
```

// This program demonstrates the Stack template.
\#include <iostream>
\#include <string>
\#include "Stack.h"
using namespace std;
// Constants for the menu choices
const int PUSH_CHOICE = 1,
POP_CHOICE = 2,
QUIT_CHOICE = 3;
// Function prototypes
void menu(int \&);
void getStackSize(int \&);
void pushItem(Stack<string>\&);
void popItem(Stack<string>\&);
int main()
{
int stackSize; // The stack size
int choice; // To hold a menu choice
// Get the stack size.
getStackSize(stackSize);
// Create the stack.
Stack<string> stack(stackSize);
do
{
// Get the user's menu choice.
menu(choice);
// Perform the user's choice.
if (choice != QUIT_CHOICE)
{
switch (choice)
{
case PUSH_CHOICE:
pushItem(stack);
break;
case POP_CHOICE:
popItem(stack);
}
}
} while (choice != QUIT_CHOICE);
return 0;
}

```

\section*{Program 19-3 (continued)}

\section*{50}

51
```

/|*************************************************
// The getStackSize function gets the desired *
// stack size, which is assigned to the *
// reference parameter.
//***************************************************
void getStackSize(int \&size)

\subsection*{19.2 Dynamic Stacks}

CONCEPT: A stack may be implemented as a linked list, and expand or shrink with each push or pop operation.

A dynamic stack is built on a linked list instead of an array. A linked list-based stack offers two advantages over an array-based stack. First, there is no need to specify the starting size of the stack. A dynamic stack simply starts as an empty linked list, then expands by one node each time a value is pushed. Second, a dynamic stack will never be full, as long as the system has enough free memory.

In this section, we will look at a dynamic stack class, DynIntStack. This class is a dynamic version of the IntStack class previously discussed. The class declaration is shown here:

\section*{Contents of DynIntStack.h}
```

// Specification file for the DynIntStack class
\#ifndef DYNINTSTACK_H
\#define DYNINTSTACK_H
class DynIntStack
{
private:
// Structure for stack nodes
struct StackNode
{
int value; // Value in the node
StackNode *next; // Pointer to the next node
};
StackNode *top; // Pointer to the stack top
public:
// Constructor
DynIntStack()
{ top = nullptr; }
// Destructor
~DynIntStack();
// Stack operations
void push(int);
void pop(int \&);
bool isEmpty();
};
\#endif

```

The StackNode structure is the data type of each node in the linked list. It has a value member and a next pointer. Notice instead of a head pointer, a top pointer is defined. This member will always point to the first node in the list, which will represent the top of the stack. It is initialized to nul1ptr by the constructor, to signify the stack is empty.

The definitions of the other member functions are shown here:

\section*{Contents of DynIntStack.cpp}
```

\#include <iostream>

```
#include <iostream>
#include "DynIntStack.h"
#include "DynIntStack.h"
using namespace std;
using namespace std;
//*****************************************************
//*****************************************************
// Destructor
// Destructor
// This function deletes every node in the list. *
// This function deletes every node in the list. *
// This function deletes every node in the list. *
// This function deletes every node in the list. *
DynIntStack::~DynIntStack()
DynIntStack::~DynIntStack()
{
{
    StackNode *nodePtr = nul1ptr, *nextNode = nul1ptr;
```

    StackNode *nodePtr = nul1ptr, *nextNode = nul1ptr;
    ```
```

    // Position nodePtr at the top of the stack.
    nodePtr = top;
    // Traverse the list deleting each node.
    while (nodePtr != nullptr)
    {
        nextNode = nodePtr->next;
        delete nodePtr;
        nodePtr = nextNode;
    }
    }
/|**************************************************
// Member function push pushes the argument onto *
// the stack.
//**************************************************
void DynIntStack::push(int num)
{
StackNode *newNode = nullptr; // Pointer to a new node
// Allocate a new node and store num there.
newNode = new StackNode;
newNode->value = num;
// If there are no nodes in the list
// make newNode the first node.
if (isEmpty())
{
top = newNode;
newNode->next = nullptr;
}
else // Otherwise, insert NewNode before top.
{
newNode->next = top;
top = newNode;
}
}
//*****************************************************
// Member function pop pops the value at the top
// of the stack off, and copies it into the variable *
// passed as an argument.
|/**********************************************************
void DynIntStack::pop(int \&num)
{
StackNode *temp = nullptr; // Temporary pointer
// First make sure the stack isn't empty.
if (isEmpty())
{
cout << "The stack is empty.\n";
}
else // pop value off top of stack

```
```

    {
        num = top->value;
        temp = top->next;
        delete top;
        top = temp;
        }
    }
//********************************************************
// Member function isEmpty returns true if the stack *
// is empty, or false otherwise.
/|*********************************************************
boo1 DynIntStack::isEmpty()
{
bool status;
if (!top)
status = true;
else
status = false;
return status;
}

```

Let's look at the push operation in lines 31 through 51 of DynIntStack.cpp. First, in lines 36 and 37, a new node is allocated in memory, and the function argument is copied into its value member:
```

newNode = new StackNode;
newNode->value = num;

```

Next, in line 41, an if statement calls the isEmpty function to determine whether the stack is empty:
```

if (isEmpty())
{
top = newNode;
newNode->next = nullptr;
}

```

If isEmpty returns true, top is made to point at the new node, and the new node's next pointer is set to nullptr. After these statements execute, there will be one node in the list (and one value on the stack).

If isEmpty returns fal se in the if statement, the following statements in lines 46 through 50 are executed:
```

else // Otherwise, insert newNode before top
{
newNode->next = top;
top = newNode;
}

```

Notice newNode is being inserted in the list before the node to which top points. The top pointer is then updated to point to the new node. When this is done, newNode is at the top of the stack.

Now, let's look at the pop function in lines 59 through 75 . Just as the push function must insert nodes at the head of the list, pop must delete nodes at the head of the list. First, the function calls isEmpty in line 64 to determine whether there are any nodes in the stack. If there are none, an error message is displayed:
```

if (isEmpty())
{
cout << "The stack is empty.\n";
}

```

If isEmpty returns false, then the following statements in lines 68 through 74 are executed.
```

else // pop value off top of stack
{
num = top->value;
temp = top->next;
delete top;
top = temp;
}

```

First, the value member of the top node is copied into the num reference parameter. This saves the value for later use in the program. Next, a temporary StackNode pointer, temp, is made to point to top->next. If there are other nodes in the list, this causes temp to point to the second node. (If there are no more nodes, this will cause temp to point to nul1ptr.) Now, it is safe to delete the top node. After the top node is deleted, the top pointer is set equal to temp. This action moves the top pointer down the list by one node. The node that was previously second in the list becomes first.

The isEmpty function, in lines 82 through 92, is simple. If top is a null pointer, then the list (the stack) is empty.

Program 19-4 is a driver that demonstrates the DynIntStack class.

\section*{Program 19-4}
```

// This program demonstrates the dynamic stack.
// class DynIntClass.
\#include <iostream>
\#include "DynIntStack.h"
using namespace std;
int main()
{
int catchVar; // To hold values popped off the stack
// Create a DynIntStack object.
DynIntStack stack;
// Push 5, 10, and 15 onto the stack.
cout << "Pushing 5\n";
stack.push(5);
cout << "Pushing 10\n";
stack.push(10);

```
```

19 cout << "Pushing 15\n";
20 stack.push(15);
21
22 // Pop the values off the stack and display them.
23
cout << "Popping...\n";
stack.pop(catchVar);
cout << catchVar << endl;
stack.pop(catchVar);
cout << catchVar << endl;
stack.pop(catchVar);
cout << catchVar << endl;
// Try to pop another value off the stack.
cout << "\nAttempting to pop again... ";
stack.pop(catchVar);
return 0;
}

```

\section*{Program Output}

Pushing 5
Pushing 10
Pushing 15
Popping...
15
10
5

Attempting to pop again... The stack is empty.

\section*{A Dynamic Stack Template}

The dynamic stack class shown previously in this chapter works only with integers. A dynamic stack template can be easily designed to work with any data type, as shown by the following example:

\section*{Contents of DynamicStack.h}
```

\#ifndef DYNAMICSTACK_H
\#define DYNAMICSTACK_H
\#include <iostream>
using namespace std;
// Stack template
template <class T>
class DynamicStack
{
private:
// Structure for the stack nodes
struct StackNode
{
T value; // Value in the node
StackNode *next; // Pointer to the next node
};

```
```

3 8 DynamicStack<T>::~DynamicStack()

```

60 void DynamicStack<T>: :push(T item)
```

    StackNode *top; // Pointer to the stack top
    public:
//Constructor
DynamicStack()
{ top = nullptr; }
// Destructor
~DynamicStack();
// Stack operations
void push(T);
void pop(T \&);
bool isEmpty();
};
/|******************************************************
// Destructor
/|******************************************************
template <class T>
{
StackNode *nodePtr, *nextNode;
// Position nodePtr at the top of the stack.
nodePtr = top;
// Traverse the list deleting each node.
while (nodePtr != nullptr)
{
nextNode = nodePtr->next;
delete nodePtr;
nodePtr = nextNode;
}
}
//****************************************************************
// Member function push pushes the argument onto
// the stack.
/|***************************************************************
{
StackNode *newNode = nullptr; // Pointer to a new node
// Allocate a new node and store num there.
newNode = new StackNode;
newNode->value = item;
// If there are no nodes in the list
// make newNode the first node.
if (isEmpty())

```
```

    {
        top = newNode;
        newNode->next = nullptr;
    }
    else // Otherwise, insert NewNode before top.
    {
        newNode->next = top;
        top = newNode;
    }
    }
//*****************************************************************
// Member function pop pops the value at the top
// of the stack off, and copies it into the variable
// passed as an argument.
/|****************************************************************
template <class T>
void DynamicStack<T>::pop(T \&item)
{
StackNode *temp = nullptr; // Temporary pointer
// First make sure the stack isn't empty.
if (isEmpty())
{
cout << "The stack is empty.\n";
}
else // pop value off top of stack
{
item = top->value;
temp = top->next;
delete top;
top = temp;
}
}
//****************************************************************
// Member function isEmpty returns true if the stack
// is empty, or false otherwise.
||******************************************************************
template <class T>
bool DynamicStack<T>::isEmpty()
{
bool status;
if (!top)
status = true;
else
status = false;
return status;
}
\#endif

```

Program 19-5 demonstrates the DynamicStack template. This program is a modification of Program 19-3. It creates a stack of strings then presents a menu that allows the user to push an item onto the stack, pop an item from the stack, or quit the program.

\section*{Program 19-5}
```

\#include <iostream>
\#include <string>
\#include "DynamicStack.h"
using namespace std;
// Constants for the menu choices
const int PUSH_CHOICE = 1,
POP_CHOICE = 2,
QUIT_CHOICE = 3;
// Function prototypes
void menu(int \&);
void getStackSize(int \&);
void pushItem(DynamicStack<string> \&);
void popItem(DynamicStack<string> \&);
int main()
{
int choice; // To hold a menu choice
// Create the stack.
DynamicStack<string> stack;
do
{
// Get the user's menu choice.
menu(choice);
// Perform the user's choice.
if (choice != QUIT_CHOICE)
{
switch (choice)
{
case PUSH_CHOICE:
pushItem(stack);
break;
case POP_CHOICE:
popItem(stack);
}
}
} while (choice != QUIT_CHOICE);
return 0;
}

```
```

//**************************************************
// The menu function displays the menu and gets *
// the user's choice, which is assigned to the *
// reference parameter.
//*************************************************
void menu(int \&choice)
{
// Display the menu and get the user's choice.
cout << "What do you want to do?\n"
<< PUSH_CHOICE
<< " - Push an item onto the stack\n"
<< POP_CHOICE
<< " - Pop an item off the stack\n"
<< QUIT_CHOICE
<< " - Quit the program\n"
<< "Enter your choice: ";
cin >> choice;
// Validate the choice
while (choice < PUSH_CHOICE || choice > QUIT_CHOICE)
{
cout << "Enter a valid choice: ";
cin >> choice;
}
}
//************************************************
// The pushItem function gets an item from the
// user and pushes it onto the stack.
/|************************************************
void pushItem(DynamicStack<string> \&stack)
{
string item;
// Get an item to push onto the stack.
cin.ignore();
cout << "\nEnter an item: ";
getline(cin, item);
stack.push(item);
}
//*********************************************************
// The popItem function pops an item from the stack
|/*****************************************************
void popItem(DynamicStack<string> \&stack)
{
string item = "";
// Pop the item.
stack.pop(item);

```

\section*{Program 19-5 (continued)}
```

97 // Display the item.
98 if (item != "")
99 cout << item << " was popped.\n";
100 }

```

\section*{Program Output with Example Input Shown in Bold}

3 - Quit the program
Enter your choice: 3 Enter

\subsection*{19.3 The STL stack Container}

CONCEPT: The Standard Template Library offers a stack template, which may be implemented as a vector, a list, or a deque.

So far, the STL containers you have learned about are vectors and iists. The STL stack container may be implemented as a vector or a list. (It may also be implemented as a deque, which you will learn about later in this chapter.) Because the stack container is used to adapt these other containers, it is often referred to as a container adapter.
Here are examples of how to define a stack of ints, implemented as a vector, a 1 ist, and a deque:
```

stack<int, vector<int>> iStack; /l Vector stack
stack<int, list<int>> iStack; l/ List stack
stack<int> iStack; // Default - deque stack

```

NOTE: If you are using a compiler that is older than C++ 11, be sure to put spaces between the angled brackets that appear next to each other. Older compilers will mistake the >> characters for the stream extraction operator, >>. Here is an example of how to write the definitions for an older compiler:
```

stack< int, vector<int> > iStack; // Vector stack
stack< int, list<int> > iStack; /l List stack
stack< int > iStack; // Default - deque stack

```

Table 19-3 lists and describes some of the stack template's member functions.
Table 19-3 Some of the stack Template Member Functions

NOTE: The pop function in the stack template does not retrieve the value from the top of the stack, it only removes it. To retrieve the value, you must call the top function first.

Program 19-6 is a driver that demonstrates an STL stack implemented as a vector.

\section*{Program 19-6}
```

// This program demonstrates the STL stack
// container adapter.
\#include <iostream>
\#include <vector>
\#include <stack>
using namespace std;
int main()
{
const int MAX = 8; // Max value to store in the stack
int count; // Loop counter
// Define an STL stack
stack< int, vector<int> > iStack;
// Push values onto the stack.
for (count = 2; count < MAX; count += 2)
{
cout << "Pushing " << count << endl;
iStack.push(count);
}
// Display the size of the stack.
cout << "The size of the stack is ";
cout << iStack.size() << endl;
// Pop the values off the stack.
for (count = 2; count < MAX; count += 2)
{
cout << "Popping " << iStack.top() << endl;
iStack.pop();
}
return 0;
}

```

\section*{Program Output}

Pushing 2
Pushing 4
Pushing 6
The size of the stack is 3
Popping 6
Popping 4
Popping 2

\section*{Checkpoint}
19.1 Describe what LIFO means.
19.2 What is the difference between static and dynamic stacks? What advantages do dynamic stacks have over static stacks?
19.3 What are the two primary stack operations? Describe them both.
19.4 What STL types does the STL stack container adapt?

\subsection*{19.4 Introduction to the Queue ADT}

CONCEPT: A queue is a data structure that stores and retrieves items in a first-in, first-out manner.

\section*{Definition}

Like a stack, a queue (pronounced "cue") is a data structure that holds a sequence of elements. A queue, however, provides access to its elements in first-in, first-out (FIFO) order. The elements in a queue are processed like customers standing in a grocery checkout line: The first customer in line is the first one served.

\section*{Application of Queues}

Queue data structures are commonly used in computer operating systems. They are especially important in multiuser/multitasking environments where several users or tasks may be simultaneously requesting the same resource. Printing, for example, is controlled by a queue because only one document may be printed at a time. A queue is used to hold print jobs submitted by users of the system, while the printer services those jobs one at a time.

Communications software also uses queues to hold data received over networks. Sometimes data is transmitted to a system faster than it can be processed, so it is placed in a queue when it is received.

\section*{Static and Dynamic Queues}

Just as stacks are implemented as arrays or linked lists, so are queues. Dynamic queues offer the same advantages over static queues that dynamic stacks offer over static stacks. In fact, the primary difference between queues and stacks is the way data elements are accessed in each structure.

\section*{Queue Operations}

Just like checkout lines in a grocery store, think of queues as having a front and a rear. This is illustrated in Figure 19-8.

Figure 19-8 A queue has a front and a rear

When an element is added to a queue, it is added to the rear. When an element is removed from a queue, it is removed from the front. The two primary queue operations are enqueuing and dequeuing. To enqueue means to insert an element at the rear of a queue, and to
dequeue means to remove an element from the front of a queue. There are several different algorithms for implementing these operations. We will begin by looking at the most simple.
Suppose we have an empty static integer queue that is capable of holding a maximum of three values. With that queue, we execute the following enqueue operations:
```

enqueue(3);
enqueue(6);
enqueue(9);

```

Figure 19-9 illustrates the state of the queue after each of these enqueue operations.
Figure 19-9 State of the queue

Notice in this example the front index (which is a variable holding a subscript or perhaps a pointer) always references the same physical element. The rear index moves forward in the array as items are enqueued. Now, let's see how dequeue operations are performed. Figure 19-10 illustrates the state of the queue after each of three consecutive dequeue operations.

Figure 19-10 State of the queue

In the dequeuing operation, the element at the front of the queue is removed. This is done by moving all the elements after it forward by one position. After the first dequeue operation, the value 3 is removed from the queue and the value 6 is at the front. After the second dequeue operation, the value 6 is removed and the value 9 is at the front. Notice when only one value is stored in the queue, that value is at both the front and the rear.

When the last dequeue operation is performed in Figure 19-10, the queue is empty. An empty queue can be signified by setting both front and rear indices to -1 .
The problem with this algorithm is its inefficiency. Each time an item is dequeued, the remaining items in the queue are copied forward to their neighboring elements. The more items there are in the queue, the longer each successive dequeue operation will take.

Here is one way to overcome the problem: Make both the front and rear indices move in the array. As before, when an item is enqueued, the rear index is moved to make room for it. But in this design, when an item is dequeued, the front index moves by one element toward the rear of the queue. This logically removes the front item from the queue, and eliminates the need to copy the remaining items to their neighboring elements.
With this approach, as items are added and removed, the queue gradually "crawls" toward the end of the array. This is illustrated in Figure 19-11. The shaded squares represent the queue elements (between the front and rear).

Figure 19-11 The queue contents gradually crawl toward the end of the array

The problem with this approach is that the rear index cannot move beyond the last element in the array. The solution is to think of the array as circular instead of linear. When an item moves past the end of a circular array, it simply "wraps around" to the beginning. For example, consider the queue depicted in Figure 19-12.

Figure 19-12 A queue positioned at the end of an array

The value 3 is at the rear of the queue, and the value 7 is at the front of the queue. Now suppose an enqueue operation is performed, inserting the value 4 into the queue. Figure 19-13 shows how the rear of the queue wraps around to the beginning of the array.

Figure 19-13 The rear of the queue wraps around to the beginning
\begin{tabular}{|l|l|l|l|l|l|l|l|l|}
\hline 4 & & & & & 7 & 9 & 6 & 3 \\
\hline\([0]\) & {\([1]\)} & {\([2]\)} & {\([3]\)} & {\([4]\)} & {\([5]\)} & {\([6]\)} & {\([7]\)} & {\([8]\)} \\
\hline
\end{tabular}
\[
\begin{aligned}
& \text { rear }=0 \\
& \text { front }=5
\end{aligned}
\]

So, what is the code for wrapping the rear marker around to the opposite end of the array? One straightforward approach is to use an if statement such as
```

if (rear == queueSize - 1)
rear = 0;
else
rear++;

```

Another approach is with modular arithmetic:
```

rear = (rear + 1) % queueSize;

```

This statement uses the \% operator to adjust the value in rear to the proper position. Although this approach appears more elegant, the choice of which code to use is yours.

\section*{Detecting Full and Empty Queues with Circular Arrays}

One problem with the circular array algorithm is that, because both the front and rear indices move through the array, detecting whether the queue is full or empty is a challenge. When the rear index and the front index reference the same element, does it indicate that only one item is in the queue, or that the queue is full? A number of approaches are commonly taken, two of which are listed below:
- When moving the rear index backward, always leave one element empty between it and the front index. The queue is full when the rear index is within two positions of the front index.
- Use a counter variable to keep a total of the number of items in the queue.

Because it might be helpful to keep a count of items in the queue anyway, we will use the second method in our implementation.

\section*{A Static Queue Class}

The declaration of the IntQueue class is as follows:

\section*{Contents of IntQueue.h}
```

// Specification file for the IntQueue class
\#ifndef INTQUEUE_H
\#define INTQUEUE_H

```
```

class IntQueue
{
private:
int *queueArray; // Points to the queue array
int queueSize; // The queue size
int front; // Subscript of the queue front
int rear; // Subscript of the queue rear
int numItems; // Number of items in the queue
public:
// Constructor
IntQueue(int);
// Copy constructor
IntQueue(const IntQueue \&);
// Destructor
~IntQueue();
// Queue operations
void enqueue(int);
void dequeue(int \&);
bool isEmpty() const;
bool isFull() const;
void clear();
};
\#endif

```

Notice in addition to the operations discussed in this section, the class also declares a member function named clear. This function clears the queue by resetting the front and rear indices and setting the numItems member to 0 . The member function definitions are listed below.

\section*{Contents of IntQueue.cpp}
```

Program \(19-7\) is a driver that demonstrates the IntQueue class.

\section*{Program 19-7}
```

// This program demonstrates the IntQueue class.
\#include <iostream>
\#include "IntQueue.h"
using namespace std;
int main()
{
const int MAX_VALUES = 5; // Max number of values
// Create an IntQueue to hold the values.
IntQueue iQueue(MAX_VALUES);
// Enqueue a series of items.
cout << "Enqueuing " << MAX_VALUES << " items...\n";
for (int x = 0; x < MAX_VALUES; x++)
iQueue.enqueue(x);
// Attempt to enqueue just one more item.
cout << "Now attempting to enqueue again...\n";
iQueue.enqueue(MAX_VALUES);
// Dequeue and retrieve al1 items in the queue
cout << "The values in the queue were:\n";
while (!iQueue.isEmpty())
{
int value;
iQueue.dequeue(value);
cout << value << endl;
}
return 0;
}

```

\section*{Program Output}

Enqueuing 5 items..
Now attempting to enqueue again...
The queue is full.
The values in the queue were:
0
1
2
3
4

\section*{A Static Queue Template}

The queue class shown previously works only with integers. A queue template can be easily designed to work with any data type, as shown by the following example:

\section*{Contents of Queue.h}
```

\#ifndef QUEUE_H
\#define QUEUE_H
\#include <iostream>
using namespace std;
// Stack template
template <class T>
class Queue
{
private:
T *queueArray; // Points to the queue array
int queueSize; // The queue size
int front; // Subscript of the queue front
int rear; // Subscript of the queue rear
int numItems; // Number of items in the queue
public:
// Constructor
Queue(int);
// Copy constructor
Queue(const Queue \&);
// Destructor
~Queue();
// Queue operations
void enqueue(T);
void dequeue(T \&);
bool isEmpty() const;
bool isFul1() const;
void clear();
};
|/********************************************************************
// This constructor creates an empty queue of a specified size.
//******************************************************************
template <class T>
Queue<T>::Queue(int s)
{
queueArray = new T[s];
queueSize = s;
front = -1;
rear = -1;
numItems = 0;
}

```
```

//***************************************************************
// Copy constructor
//*****************************************************************
template <class T>
Queue<T>::Queue(const Queue \&obj)
{
// Allocate the queue array.
queueArray = new T[obj.queueSize];
// Copy the other object's attributes.
queueSize = obj.queueSize;
front = obj.front;
rear = obj.rear;
numItems = obj.numItems;
// Copy the other object's queue array.
for (int count = 0; count < obj.queueSize; count++)
queueArray[count] = obj.queueArray[count];
}
|/****************************************************************
// Destructor

{
bool status;
if (numItems < queueSize)
status = false;
else
status = true;
return status;
}
//******************************************************************
// clear sets the front and rear indices, and sets numItems to 0.
/|*******************************************************************
template <class T>
{
front = queueSize - 1;
rear = queueSize - 1;
numItems = 0;
}
\#endif

```

Program 19-8 demonstrates the Queue template. It creates a queue that can hold strings, then prompts the user to enter a series of names that are enqueued. The program then dequeues all of the names and displays them.

\section*{Program 19-8}
```

// This program demonstrates the Queue template.
\#include <iostream>
\#include <string>
\#include "Queue.h"
using namespace std;
const int QUEUE_SIZE = 5;
int main()
{
string name;
// Create a Queue.
Queue<string> queue(QUEUE_SIZE);
// Enqueue some names.
for (int count = 0; count < QUEUE_SIZE; count++)
{
cout << "Enter a name: ";
getline(cin, name);
queue.enqueue(name);
}
// Dequeue the names and display them.
cout << "\nHere are the names you entered:\n";
for (int count = 0; count < QUEUE_SIZE; count++)
{
queue.dequeue(name);
cout << name << endl;
}
return 0;
}

```

\section*{Program Output with Example Input Shown in Bold}
```

Enter a name: Chris Enter
Enter a name: Kathryn Enter
Enter a name: Alfredo Enter
Enter a name: Lori Enter
Enter a name: Kelly Enter
Here are the names you entered:
Chris
Kathryn
Alfredo
Lori
Kelly

```

\subsection*{19.5 Dynamic Queues}

CONCEPT: A queue may be implemented as a linked list and expand or shrink with each enqueue or dequeue operation.

Dynamic queues, which are built around linked lists, are much more intuitive to understand than static queues. A dynamic queue starts as an empty linked list. With the first enqueue operation, a node is added, which is pointed to by the front and rear pointers. As each new item is added to the queue, a new node is added to the rear of the list, and the rear pointer is updated to point to the new node. As each item is dequeued, the node pointed to by the front pointer is deleted, and front is made to point to the next node in the list. Figure 19-14 shows the structure of a dynamic queue.

Figure 19-14 A dynamic queue

A dynamic integer queue class is listed here:

\section*{Contents of DynIntQueue.h}
```

```
            item = front->value;
```

103
116 // is empty, and false otherwise.
117 //*
118 template <class T>
119 bool DynamicQueue<T>::isEmpty() const
120
121
122
132 // in the queue.
133 //*
134 template <class T>
135 void DynamicQueue<T>::clear()
136
137 T value; // Dummy variable for dequeue

Program 19-10 demonstrates the DynamicQueue template. This program is a modification of Program 19-8. It creates a queue that can hold strings then prompts the user to enter a series of names that are enqueued. The program then dequeues all of the names and displays them. (The program's output is the same as that of Program 19-8.)

## Program 19-10

1 // This program demonstrates the DynamicQueue template.
2 \#include <iostream>
3 \#include <string>
4 \#include "DynamicQueue.h"
5 using namespace std;
6

## Program 19-10 (continued)

```
const int QUEUE_SIZE = 5;
int main()
{
    string name;
    // Create a Queue.
    DynamicQueue<string> queue;
    // Enqueue some names.
    for (int count = 0; count < QUEUE_SIZE; count++)
    {
        cout << "Enter a name: ";
        getline(cin, name);
        queue.enqueue(name);
    }
    // Dequeue the names and display them.
    cout << "\nHere are the names you entered:\n";
    for (int count = 0; count < QUEUE_SIZE; count++)
    {
        queue.dequeue(name);
        cout << name << endl;
        }
        return 0;
}
```

## Program Output

(Same as Program 19-8's output.)

### 19.6 The STL deque and queue Containers

CONCEPT: The Standard Template Library provides two containers, deque and queue, for implementing queue-like data structures.

In this section, we will examine two ADTs offered by the Standard Template Library: deque and queue. A deque (pronounced "deck" or "deek") is a double-ended queue. It is similar to a vector, but allows efficient access to values at both the front and the rear. The queue ADT is a container adapter that uses a deque as its default container.

## The deque Container

Think of the deque container as a vector that provides quick access to the element at its front as well as at the back. (Like vector, deque also provides access to its elements with the [] operator.)

Programs that use the deque ADT must include the deque header. Because we are concentrating on its queue-like characteristics, we will focus our attention on the push_back, pop_front, and front member functions. Table 19-4 describes them.

Table 19-4 Some of the deque Template Member Functions

| Member Function | Examples and Description |
| :---: | :---: |
| push_back | iDeque.push_back(); <br> Accepts as an argument a value to be inserted into the deque. The argument is inserted after the last element. (Pushed onto the back of the deque.) |
| pop_front | iDeque.pop_front(); <br> Removes the first element of the deque. |
| front | cout << iDeque.front() << end; <br> front returns a reference to the first element of the deque. |

Program 19-11 demonstrates the deque container.

## Program 19-11

```
// This program demonstrates the STL deque container.
#include <iostream>
#include <deque>
using namespace std;
int main()
{
    const int MAX = 8; // Max value
    int count; // Loop counter
    // Create a deque object.
    deque<int> iDeque;
    // Enqueue a series of numbers.
    cout << "I will now enqueue items...\n";
    for (count = 2; count < MAX; count += 2)
    {
        cout << "Pushing " << count << endl;
        iDeque.push_back(count);
    }
    // Dequeue and display the numbers.
    cout << "I will now dequeue items...\n";
    for (count = 2; count < MAX; count += 2)
    {
        cout << "Popping "<< iDeque.front() << end1;
        iDeque.pop_front();
    }
        return 0;
}
```

## The queue Container Adapter

VideoNote
Storing Objects in an STL queue

The queue container adapter can be built upon vectors, lists, or deques. By default, it uses deque as its base.
The insertion and removal operations supported by queue are the same as those supported by the stack ADT: push, pop, and front. There are differences in their behavior, however. The queue version of push always inserts an element at the rear of the queue. The queue version of pop always removes an element from the structure's front. The front function returns the value of the element at the front of the queue.

Program 19-12 demonstrates a queue. Because the definition of the queue does not specify which type of container is being adapted, the queue will be built on a deque.

## Program 19-12

```
// This program demonstrates the STL queue container adapter.
#include <iostream>
#include <queue>
using namespace std;
int main()
{
    const int MAX = 8; // Max value
    int count; // Loop counter
    // Define a queue object.
    queue<int> iQueue;
    // Enqueue a series of numbers.
    cout << "I will now enqueue items...\n";
    for (count = 2; count < MAX; count += 2)
    {
        cout << "Pushing "<< count << endl;
        iQueue.push(count);
    }
    // Dequeue and display the numbers.
    cout << "I will now dequeue items...\n";
    for (count = 2; count < MAX; count += 2)
```

```
25 {
        cout << "Popping "<< iQueue.front() << endl;
        iQueue.pop();
    }
        return 0;
}
```

## Program Output

```
I will now enqueue items...
```

Pushing 2
Pushing 4
Pushing 6
I will now dequeue items...
Popping 2
Popping 4
Popping 6

## Review Questions and Exercises

## Short Answer

1. What does LIFO mean?
2. What element is always retrieved from a stack?
3. What is the difference between a static stack and a dynamic stack?
4. Describe two operations that all stacks perform.
5. Describe two operations that static stacks must perform.
6. The STL stack is considered a container adapter. What does that mean?
7. What types may the STL stack be based on? By default, what type is an STL stack based on?
8. What does FIFO mean?
9. When an element is added to a queue, where is it added?
10. When an element is removed from a queue, where is it removed from?
11. Describe two operations that all queues perform.
12. What two queue-like containers does the STL offer?

## Fill-in-the-Blank

13. $\mathrm{A}(\mathrm{n})$ $\qquad$ is a LIFO structure while $\mathrm{a}(\mathrm{n})$ $\qquad$ is a FIFO structure.
14. The two primary stack operations are $\qquad$ and $\qquad$ .
15. $\qquad$ stacks and queues are implemented as arrays.
16. A(n) $\qquad$ operation causes a value to be stored on the top of a stack.
17. The statement stack< int, vector<int\gg vStk; defines an STL stack container implemented as a $\qquad$ .
18. The size of a $\qquad$ stack expands or shrinks with each push or pop operation.
19. The enqueue operation of a queue adds an element at the $\qquad$ of a queue.
20. The two ADTs in the Standard Template Library that exhibit queue-like behavior are
$\qquad$ and $\qquad$ .
21. The queue ADT, by default, adapts the $\qquad$ container.

## Algorithm Workbench

22. Suppose the following operations are performed on an empty stack:
```
push(0);
push(9);
push(12);
push(1);
```

Insert numbers in the following diagram to show what will be stored in the static stack after the operations above have executed.

23. Suppose the following operations are performed on an empty stack:

```
push(8);
push(7);
pop();
push(19);
push(21);
pop();
```

Insert numbers in the following diagram to show what will be stored in the static stack after the operations above have executed.

24. Suppose the following operations are performed on an empty queue:

```
enqueue(5);
enqueue(7);
enqueue(9) ;
enqueue(12);
```

Insert numbers in the following diagram to show what will be stored in the static queue after the operations above have executed.

|  |  |  |  |
| :--- | :--- | :--- | :--- |
| rear |  |  |  |
| front |  |  |  |

25. Suppose the following operations are performed on an empty queue:
enqueue (5) ;
enqueue (7) ;
dequeue () ;
enqueue (9) ;
enqueue (12) ;
dequeue();
enqueue (10) ;
Insert numbers in the following diagram to show what will be stored in the static queue after the operations above have executed.

26. What problem is overcome by using a circular array for a static queue?
27. Write two different code segments that may be used to wrap an index back around to the beginning of an array when it moves past the end of the array. Use an if/else statement in one segment, and modular arithmetic in the other.

## True or False

28. T F The static stack must be checked for stack overflow during a push operation.
29. T F The first element inserted in a queue is the last to be deleted.
30. $\mathrm{T} F \mathrm{~F}$ The push operation inserts an element at the end of a stack.
31. T F A dynamic stack is built on a linked list rather than arrays.
32. T F A queue data structure can be used to hold multiple task requests that are to be executed in the CPU.

## Programming Challenges

1. Static Stack Template

Write your own version of a class template that will create a static stack of any data type. Demonstrate the class with a driver program.

## 2. Dynamic Stack Template

Write your own version of a class template that will create a dynamic stack of any data type. Demonstrate the class with a driver program.

## 3. Static Queue Template

Write your own version of a class template that will create a static queue of any data type. Demonstrate the class with a driver program.

## 4. Dynamic Queue Template

Write your own version of a class template that will create a dynamic queue of any data type. Demonstrate the class with a driver program.

## 5. Error Testing

The DynIntStack and DynIntQueue classes shown in this chapter are abstract data types using a dynamic stack and dynamic queue, respectively. The classes do not currently test for memory allocation errors. Modify the classes so they determine whether new nodes cannot be created by handling the bad_alloc exception.

NOTE: If you have already done Programming Challenges 2 and 4, modify the templates you created.

## 6. Dynamic String Stack

Design a class that stores strings on a dynamic stack. The strings should not be fixed in length. Demonstrate the class with a driver program.

## 7. Dynamic MathStack

The MathStack class shown in this chapter has only two member functions: add and sub. Write the following additional member functions:

| Function | Description |
| :--- | :--- |
| mult | Pops the top two values off the stack, multiplies them, and pushes <br> their product onto the stack. |
| div | Pops the top two values off the stack, divides the second value by <br> the first, and pushes the quotient onto the stack. |
| mu1tA11 | Pops all values off the stack, adds them, and pushes their sum onto <br> the stack. <br> Pops all values off the stack, multiplies them, and pushes their prod- <br> uct onto the stack. |

Demonstrate the class with a driver program.

## 8. Dynamic MathStack Template

Currently, the MathStack class is derived from the IntStack class. Modify it so it is a template, derived from the template you created in Programming Challenge 2 (Dynamic Stack Template).

## 9. Reversal of Lines of a Multiline Text File

Write a program that opens a text file and extracts its lines into a stack of strings. The program should then pop the strings from the stack and save them in a second text file. Thus, the first line of the first file should be ordered as the last line of the second file, the second line should be ordered as the second last line, and so on.

## 10. Encrypting Filter

Write a program that opens a text file and reads its contents into a queue of characters. The program should then dequeue each character and substitute it with the character that comes five places after it in the ASCII character set, and store it in a second file.

## 11. File Compare

Write a program that opens two text files and reads their contents into two separate queues. The program should then determine whether the files are identical by comparing the characters in the queues. When two nonidentical characters are encountered, the program should display a message indicating that the files are not the same. If both queues contain the same set of characters, a message should be displayed indicating that the files are identical.

## 12. Inventory Bin Stack

Design an inventory class that stores the following members:

$$
\begin{array}{ll}
\text { serialNum: } & \text { An integer that holds a part's serial number. } \\
\text { manufactDate: } & \text { A member that holds the date the part was manufactured. } \\
\text { lotNum: } & \text { An integer that holds the part's lot number. }
\end{array}
$$

The class should have appropriate member functions for storing data into, and retrieving data from, these members.
Next, design a stack class that can hold objects of the class described above. If you wish, you may use the template you designed in Programming Challenge 1 or 2.
Last, design a program that uses the stack class described above. The program should have a loop that asks the user if he or she wishes to add a part to inventory, or take a part from inventory. The loop should repeat until the user is finished.
If the user wishes to add a part to inventory, the program should ask for the serial number, date of manufacture, and lot number. The data should be stored in an inventory object, and pushed onto the stack.
If the user wishes to take a part from inventory, the program should pop the top-most part from the stack and display the contents of its member variables.
When the user finishes the program, it should display the contents of the member values of all the objects that remain on the stack.

## 13. Double-ended Queue

Write a class template that will implement a double-ended dynamic queue of any data type. The template should have the member functions insert_front, delete_front, insert_rear, and delete_rear. Demonstrate the class in a driver program.
14. Evaluation of a Postfix Expression

Write a program to evaluate a postfix expression using a stack. To evaluate the string, the program should scan each character in the string. If the character is a digit, its value is pushed on a stack. If the character is an operator $\Theta(+,-, *$, or $/)$, the top two elements are popped in the variables $A$ and $B$, the operation $B \Theta A$ is performed, and the result is pushed back on the stack. The final result is stored on the top of the stack.

## 15. Test of Language

A language allows strings to be only in the form of $a^{n} b^{n}$, where $n$ is a positive integer. Thus, the string ' $a$ aaaabbbbb' is valid but the strings ' $a a a a b b b$ ', or ' $a a a b b b b$ ', or ' $a a b b a a b b$ ' are invalid.

Write a function that accepts a string as an argument and tests whether it belongs to the language. The function should scan the string from the beginning, push all the ' $a$ 's in a stack, and start to pop them when the ' $b$ 's are encountered. The function should report any discrepancies in the number of ' $a$ 's and ' $b$ 's as a failure. Demonstrate the function in a program.

### 20.1 Introduction to Recursion

CONCEPT: A recursive function is one that calls itself.
You have seen instances of functions calling other functions. Function A can call function B, which can then call function C. It's also possible for a function to call itself. A function that calls itself is a recursive function. Look at this message function:

```
void message()
{
    cout << "This is a recursive function.\n";
    message();
}
```

This function displays the string "This is a recursive function.ln", then calls itself. Each time it calls itself, the cycle is repeated. Can you see a problem with the function? There's no way to stop the recursive calls. This function is like an infinite loop because there is no code to stop it from repeating.

NOTE: The function example message will eventually cause the program to crash. Do you remember learning in Chapter 19 that the system stores temporary data on a stack each time a function is called? Eventually, these recursive function calls will use up all available stack memory and cause it to overflow.

Like a loop, a recursive function must have some method to control the number of times it repeats. The following is a modification of the message function. It passes an integer argument that holds the number of times the function is to call itself.

```
void message(int times)
{
    if (times > 0)
    {
        cout << "This is a recursive function.\n";
        message(times - 1);
    }
}
```

This function contains an if statement that controls the repetition. As long as the times argument is greater than zero, it will display the message and call itself again. Each time it calls itself, it passes times - 1 as the argument. For example, let's say a program calls the function with the following statement:

```
message(5);
```

The argument, 5 , will cause the function to call itself five times. The first time the function is called, the if statement will display the message then call itself with 4 as the argument. Figure 20-1 illustrates this.

Figure 20-1 Recursive function call

The diagram in Figure 20-1 illustrates two separate calls of the message function. Each time the function is called, a new instance of the times parameter is created in memory. The first time the function is called, the times parameter is set to 5 . When the function calls itself, a new instance of times is created, and the value 4 is passed into it. This cycle repeats until, finally, zero is passed to the function. This is illustrated in Figure 20-2.

As you can see from Figure 20-2, the function is called a total of six times. The first time it is called from main, and the other five times it calls itself, so the depth of recursion is five. When the function reaches its sixth call, the times parameter will be set to 0 . At that point, the if statement's conditional expression will be false, so the function will return. Control

Figure 20-2 Recursive function calls

of the program will return from the sixth instance of the function to the point in the fifth instance directly after the recursive function call:

```
void message (int times)
{
    if (times > 0
    {
        cout << "This is a recursive function.\n"
        message (times - 1); \longleftarrow Recursive call
    }
}}\mathrm{ Control returns here from the recursive call, causing the function to return.
```

Because there are no more statements to be executed after the function call, the fifth instance of the function returns control of the program back to the fourth instance. This repeats until all instances of the function return. Program 20-1 demonstrates the recursive message function.

## Program 20-1

1 // This program demonstrates a simple recursive function.
2 \#include <iostream>
3 using namespace std;
4

## Program 20-1 (continued)

```
// Function prototype
void message(int);
int main()
{
    message(5);
    return 0;
}
//**************************************************************
// Definition of function message. If the value in times is *
// greater than 0, the message is displayed and the *
// function is recursively called with the argument *
// times - 1.
//****************************************************************
void message(int times)
{
    if (times > 0)
    {
        cout << "This is a recursive function.\n";
        message(times - 1);
    }
}
```

## Program Output

This is a recursive function.
This is a recursive function.
This is a recursive function.
This is a recursive function.
This is a recursive function.
To further illustrate the inner workings of this recursive function, let's look at another version of the program. In Program 20-2, a message is displayed each time the function is entered, and another message is displayed just before the function returns.

## Program 20-2

```
// This program demonstrates a simple recursive function.
#include <iostream>
using namespace std;
// Function prototype
void message(int);
int main()
{
        message(5);
        return 0;
}
```

```
//*****************************************************************
// Definition of function message. If the value in times is *
// greater than 0, the message is displayed and the function *
// is recursively called with the argument times - 1.
/l*****************************************************************
void message(int times)
{
    cout << "message called with " << times << " in times.\n";
    if (times > 0)
    {
            cout << "This is a recursive function.\n";
            message(times - 1);
    }
    cout << "message returning with " << times;
    cout << " in times.\n";
}
```

## Program Output

```
message called with 5 in times.
This is a recursive function.
message called with 4 in times.
This is a recursive function.
message called with 3 in times.
This is a recursive function.
message called with 2 in times.
This is a recursive function.
message called with 1 in times.
This is a recursive function.
message called with 0 in times.
message returning with 0 in times.
message returning with 1 in times.
message returning with 2 in times.
message returning with 3 in times.
message returning with 4 in times.
message returning with 5 in times.
```

### 20.2 Solving Problems with Recursion

CONCEPT: A problem can be solved with recursion if it can be broken down into successive smaller problems that are identical to the overall problem.

Programs 20-1 and 20-2 in the previous section show simple demonstrations of how a recursive function works. But these examples don't show us why we would want to write a recursive function. Recursion can be a powerful tool for solving repetitive problems and is an important topic in upper-level computer science courses. What might not be clear to you yet is how to use recursion to solve a problem.

First, it should be noted that recursion is never absolutely required to solve a problem. Any problem that can be solved recursively can also be solved iteratively, with a loop. In fact, recursive algorithms are usually less efficient than iterative algorithms. This is because a function call requires several actions to be performed by the C++ runtime system. These actions include allocating memory for parameters and local variables and storing the address of the program location where control returns after the function terminates. These actions, which are sometimes referred to as overhead, take place with each function call. Such overhead is not necessary with a loop.
Some repetitive problems, however, are more easily solved with recursion than with iteration. Where an iterative algorithm might result in faster execution time, the programmer might be able to design a recursive algorithm faster.

In general, a recursive function works like this:

- If the problem can be solved now, without recursion, then the function solves it and returns.
- If the problem cannot be solved now, then the function reduces it to a smaller but similar problem and calls itself to solve the smaller problem.
In order to apply this approach, we first identify at least one case in which the problem can be solved without recursion. This is known as the base case. Second, we determine a way to solve the problem in all other circumstances using recursion. This is called the recursive case. In the recursive case, we must always reduce the problem to a smaller version of the original problem. By reducing the problem with each recursive call, the base case will eventually be reached, and the recursion will stop.

## Example: Using Recursion to Calculate the Factorial of a Number

Let's take an example from mathematics to examine an application of recursion. In mathematics, the notation $n$ ! represents the factorial of the number $n$. The factorial of a nonnegative number can be defined by the following rules:

If $n=0$ then $\quad n!=1$
If $n>0$ then $n!=1 \times 2 \times 3 \times \ldots \times n$
Let's replace the notation $n$ ! with factorial $(n)$, which looks a bit more like computer code, and rewrite these rules as

If $n=0$ then $\quad$ factorial $(n)=1$
If $n>0$ then $\quad$ factorial $(n)=1 \times 2 \times 3 \times \ldots \times n$
These rules state that when $n$ is 0 , its factorial is 1 . When $n$ is greater than 0 , its factorial is the product of all the positive integers from 1 up to $n$. For instance, factorial(6) is calculated as $1 \times 2 \times 3 \times 4 \times 5 \times 6$.

When designing a recursive algorithm to calculate the factorial of any number, we first identify the base case, which is the part of the calculation we can solve without recursion. That is the case where $n$ is equal to 0 .
If $n=0$ then $\quad$ factorial $(n)=1$

This tells us how to solve the problem when $n$ is equal to 0 , but what do we do when $n$ is greater than 0 ? That is the recursive case, or the part of the problem we use recursion to solve. This is how we express it:
If $n>0$ then $\quad$ factorial $(n)=n \times$ factorial $(n-1)$
This states if $n$ is greater than 0 , the factorial of $n$ is $n$ times the factorial of $n-1$. Notice how the recursive call works on a reduced version of the problem, $n-1$. So, our recursive rule for calculating the factorial of a number might look like this:
If $n=0$ then $\quad$ factorial $(n)=1$
If $n>0$ then $\quad$ factorial $(n)=n \times$ factorial $(n-1)$
The following pseudocode shows how we might implement the factorial algorithm as a recursive function:

```
factorial(n)
    If n is O then
        return 1
    else
        return n times the factorial of n - 1
end factorial
```

Here is the C++ code for such a function:

```
int factorial(int n)
{
        if (n == 0)
            return 1; // Base case
        else
    return n * factorial(n - 1); // Recursive case
}
```

Program 20-3 demonstrates the recursive factorial function.

## Program 20-3

```
// This program demonstrates a recursive function to
// calculate the factorial of a number.
#include <iostream>
using namespace std;
// Function prototype
int factorial(int);
int main()
{
    int number;
```

(program continues)

## Program 20-3 (continued)

```
    // Get a number from the user.
    cout << "Enter an integer value and I will display\n";
    cout << "its factorial: ";
    cin >> number;
    // Display the factorial of the number.
    cout << "The factorial of " << number << " is ";
    cout << factorial(number) << endl;
    return 0;
}
//******************************************************************
// Definition of factorial. A recursive function to calculate *
// the factorial of the parameter n.
//***************************************************************
int factorial(int n)
{
    if (n == 0)
    return 1; // Base case
        else
            return n * factorial(n - 1); // Recursive case
}
```

## Program Output with Example Input Shown in Bold

Enter an integer value and I will display
its factorial: 4 Enter
The factorial of 4 is 24

In the example run of the program, the factorial function is called with the argument 4 passed into $n$. Because $n$ is not equal to 0 , the if statement's else clause executes the following statement, in line 34:

```
return n * factorial(n - 1);
```

Although this is a return statement, it does not immediately return. Before the return value can be determined, the value of factorial (num - 1) must be determined. The factorial function is called recursively until the fifth call, in which the n parameter will be set to zero. The diagram in Figure 20-3 illustrates the value of n and the return value during each call of the function.

This diagram illustrates why a recursive algorithm must reduce the problem with each recursive call. Eventually the recursion has to stop in order for a solution to be reached. If each recursive call works on a smaller version of the problem, then the recursive calls work toward the base case. The base case does not require recursion, so it stops the chain of recursive calls.

Usually, a problem is reduced by making the value of one or more parameters smaller with each recursive call. In our factorial function, the value of the parameter $n$ gets closer to 0 with each recursive call. When the parameter reaches 0 , the function returns a value without making another recursive call.

Figure 20-3 Recursive function calls

## Example: Using Recursion to Count Characters

Let's look at another simple example of recursion. The following function counts the number of times a specific character appears in a string. The line numbers are from Program 20-4, which we will examine momentarily.

```
int numChars(char search, string str, int subscript)
{
    if (subscript >= str.length())
    {
        // Base case: The end of the string is reached.
        return 0;
    }
```

```
    else if (str[subscript] == search)
    {
        // Recursive case: A matching character was found.
        // Return 1 plus the number of times the search
        // character appears in the rest of the string.
        return 1 + numChars(search, str, subscript+1);
    }
        else
        {
        // Recursive case: A character that does not match the
        // search character was found. Return the number of times
        // the search character appears in the rest of the string.
        return numChars(search, str, subscript+1);
    }
    }
```

The function's parameters are

- search: The character to be searched for and counted
- str: a string object containing the string to be searched
- subscript: The starting subscript for the search

When this function examines a character in the string, three possibilities exist:

1. The end of the string has been reached. This is the base case, because there are no more characters to search.
2. A character that matches the search character is found. This is a recursive case because we still have to search the rest of the string.
3. A character that does not match the search character is found. This is also a recursive case because we still have to search the rest of the string.

Let's take a closer look at the code. The first if statement, in line 31, determines whether the end of the string has been reached:

```
if (subscript >= str.length())
```

Reaching the end of the string is the base case of the problem. If the end of the string has been reached, the function returns 0 , indicating 0 matching characters were found. Otherwise, the following e1se if clause, in lines 36 through 42, is executed:

```
e1se if (str[subscript] == search)
{
    // Recursive case: A matching character was found.
    // Return 1 plus the number of times the search
    // character appears in the rest of the string.
    return 1 + numChars(search, str, subscript+1);
}
```

If str[subscript] contains the search character, then we have found one matching character. But because we have not reached the end of the string, we must continue to search the rest of the string for more matching characters. So, at this point, the function performs a recursive call. The return statement returns 1 plus the number of times the search character appears in the string, starting at subscript +1 . In essence, this statement returns 1 plus the number of times the search character appears in the rest of the string.

Finally, if str[subscript] does not contain the search character, the following else clause in lines 43 through 49 is executed:

```
e1se
{
    // Recursive case: A character that does not match the
    // search character was found. Return the number of times
    // the search character appears in the rest of the string.
    return numChars(search, str, subscript+1);
}
```

The return statement in line 48 makes a recursive call to search the remainder of the string. In essence, this code returns the number of times the search character appears in the rest of the string. Program 20-4 demonstrates the function.

## Program 20-4

```
// This program demonstrates a recursive function for counting
// the number of times a character appears in a string.
#include <iostream>
#include <string>
using namespace std;
// Function prototype
int numChars(char, string, int);
int main()
{
    string str = "abcddddef";
    // Display the number of times the letter
    // 'd' appears in the string.
    cout << "The letter d appears "
            << numChars('d', str, 0) << " times.\n";
        return 0;
}
//**************************************************
// Function numChars. This recursive function *
// counts the number of times the character *
// search appears in the string str. The search *
// begins at the subscript stored in subscript.
//**************************************************
int numChars(char search, string str, int subscript)
{
    if (subscript >= str.length())
    {
            // Base case: The end of the string is reached.
            return 0;
        }
        else if (str[subscript] == search)
```

```
Program 20-4 (continued)
37 {
        // Recursive case: A matching character was found.
        // Return 1 plus the number of times the search
        // character appears in the rest of the string.
        return 1 + numChars(search, str, subscript+1);
    }
        else
        {
        // Recursive case: A character that does not match the
        // search character was found. Return the number of times
        // the search character appears in the rest of the string.
        return numChars(search, str, subscript+1);
    }
}
```

## Program Output

The letter d appears 4 times.

## Direct and Indirect Recursion

The examples we have discussed so far show recursive functions that directly call themselves. This is known as direct recursion. There is also the possibility of creating indirect recursion in a program. This occurs when function A calls function B, which in turn calls function A. There can even be several functions involved in the recursion. For example, function A could call function B, which could call function C, which calls function A.

## Checkpoint

20.1 What happens if a recursive function never returns?
20.2 What is a recursive function's base case?
20.3 What will the following program display?

```
#include <iostream>
using namespace std;
// Function prototype
void showMe(int arg);
int main()
{
    int num = 0;
    showMe(num);
    return 0;
}
void showMe(int arg)
{
    if (arg < 10)
            showMe(++arg);
        else
            cout << arg << endl;
}
```

20.4 What is the difference between direct and indirect recursion?

### 20.3 Focus on Problem Solving and Program Design: The Recursive gcd Function

CONCEPT: The gcd function uses recursion to find the greatest common divisor (GCD) of two numbers.

Our next example of recursion is the calculation of the greatest common divisor, or GCD, of two numbers. Using Euclid's algorithm, the GCD of two positive integers, $x$ and $y$, is:

$$
\begin{array}{ll}
\operatorname{gcd}(x, y)=y ; & \text { if } y \text { divides } x \text { evenly } \\
\operatorname{gcd}(y, \text { remainder of } x / y) ; & \text { otherwise }
\end{array}
$$

The definition above states the GCD of $x$ and $y$ is $y$ if $x / y$ has no remainder. Otherwise, the answer is the GCD of $y$ and the remainder of $x / y$. Program 20-5 shows the recursive C++ implementation.

## Program 20-5

```
// This program demonstrates a recursive function to calculate
// the greatest common divisor (gcd) of two numbers.
#include <iostream>
using namespace std;
// Function prototype
int gcd(int, int);
int main()
{
    int num1, num2;
    // Get two numbers.
    cout << "Enter two integers: ";
    cin >> num1 >> num2;
    // Display the GCD of the numbers.
    cout << "The greatest common divisor of " << num1;
    cout << " and " << num2 << " is ";
    cout << gcd(num1, num2) << endl;
    return 0;
}
//**********************************************************
// Definition of gcd. This function uses recursion to *
// calculate the greatest common divisor of two integers, *
// passed into the parameters }x\mathrm{ and }y\mathrm{ .
//***********************************************************
int gcd(int x, int y)
```

```
Program 20-5 (continued)
31 \{
if (x \% y == 0)
    return y; // Base case
else
    return \(\operatorname{gcd}(y, x \% y) ; \quad / /\) Recursive case
\}
```

## Program Output with Example Input Shown in Bold

Enter two integers: 4928 Enter
The greatest common divisor of 49 and 28 is 7

### 20.4 Focus on Problem Solving and Program Design: Solving Recursively Defined Problems

CONCEPT: Some mathematical problems are designed for a recursive solution.
Some mathematical problems are designed to be solved recursively. One well-known example is the calculation of Fibonacci numbers. The Fibonacci numbers, named after the Italian mathematician Leonardo Fibonacci (born circa 1170), are the following sequence:
$0,1,1,2,3,5,8,13,21,34,55,89,144,233, \ldots$
Notice after the second number, each number in the series is the sum of the two previous numbers. The Fibonacci series can be defined as
$F_{0}=0$
$F_{1}=1$
$F_{N}=F_{N-1}+F_{N-2}$ for $N \geq 2$.
A recursive $\mathrm{C}++$ function to calculate the $n$th number in the Fibonacci series is shown here:

```
int fib(int n)
{
        if (n <= 0)
            return 0;
        else if (n == 1)
            return 1;
        else
            return fib(n - 1) + fib(n - 2);
}
```

The function is demonstrated in Program 20-6, which displays the first 10 numbers in the Fibonacci series.

## Program 20-6

```
// This program demonstrates a recursive function
// that calculates Fibonacci numbers.
#include <iostream>
using namespace std;
```

5

```
// Function prototype
int fib(int);
int main()
{
    cout << "The first 10 Fibonacci numbers are:\n";
    for (int x = 0; x < 10; x++)
        cout << fib(x) << " ";
    cout << endl;
    return 0;
}
//******************************************
// Function fib. Accepts an int argument *
// in n. This function returns the nth *
// Fibonacci number.
//******************************************
int fib(int n)
{
    if (n <= 0)
        return 0; // Base case
        else if (n == 1)
        return 1; // Base case
        else
            return fib(n - 1) + fib(n - 2); // Recursive case
}
```

## Program Output

The first 10 Fibonacci numbers are:
0112358132134
Another such example is Ackermann's function. A Programming Challenge at the end of this chapter will ask you to write a recursive function that calculates Ackermann's function.

### 20.5 Focus on Problem Solving and Program Design: Recursive Linked List Operations

CONCEPT: Recursion can be used to traverse the nodes in a linked list.
Recall in Chapter 18, we discussed a class named NumberList that holds a linked list of double values. In this section, we will modify the class by adding recursive member functions. The functions will use recursion to traverse the linked list and perform the following operations:

- Count the number of nodes in the list.

To count the number of nodes in the list by recursion, we introduce two new member functions: numNodes and countNodes. countNodes is a private member function that uses recursion, and numNodes is the public interface that calls it.

- Display the value of the list nodes in reverse order.

To display the nodes in the list in reverse order, we introduce two new member functions: displayBackwards and showReverse. showReverse is a private member function that uses recursion, and displayBackwards is the public interface that calls it.

The class declaration, which is saved in NumberList.h, is shown here:

```
// Specification file for the NumberList class
#ifndef NUMBERLIST_H
#define NUMBERLIST_H
class NumberList
{
private:
    // Declare a structure for the list
    struct ListNode
    {
                double value;
                struct ListNode *next;
    };
    ListNode *head; // List head pointer
    // Private member functions
    int countNodes(ListNode *) const;
    void showReverse(ListNode *) const;
pub1ic:
    // Constructor
    NumberList()
        { head = nul1ptr; }
    // Destructor
    ~NumberList();
    // Linked List Operations
    void appendNode(doub1e);
    void insertNode(doub1e);
    void deleteNode(double);
    void displayList() const;
    int numNodes() const
        { return countNodes(head); }
    void displayBackwards() const
        { showReverse(head); }
};
#endif
```

## Counting the Nodes in the List

The numNodes function is declared inline. It simply calls the countNodes function and passes the head pointer as an argument. (Because the head pointer, which is private, must be passed to countNodes, the numNodes function is needed as an interface.)

The function definition for countNodes is shown here:

```
1 7 3 \text { int NumberList::countNodes(ListNode *nodePtr) const}
174 {
175 if (nodePtr != nullptr)
176 return 1 + countNodes(nodePtr->next);
177 else
178 return 0;
179 }
```

The function's recursive logic can be expressed as:

```
If the current node has a value
    Return 1 + the number of the remaining nodes
Else
    Return 0
End If
```

Program 20-7 demonstrates the function.

## Program 20-7

```
// This program counts the nodes in a list.
#include <iostream>
#include "NumberList.h"
using namespace std;
int main()
{
    const int MAX = 10; // Maximum number of values
    // Define a NumberList object.
    NumberList list;
    // Build the list with a series of numbers.
    for (int x = 0; x < MAX; x++)
        list.insertNode(x);
        // Display the number of nodes in the list.
        cout << "The number of nodes is "
            << list.numNodes() << endl;
        return 0;
}
```

## Program Output

The number of nodes is 10

## Displaying List Nodes in Reverse Order

The technique for displaying the list nodes in reverse order is designed like the node counting procedure: A public member function, which serves as an interface, passes the head pointer to a private member function. The public displayBackwards function, declared
inline, is the interface. It calls the showReverse function and passes the head pointer as an argument. The function definition for showReverse is shown here:

```
1 8 7 \text { void NumberList::showReverse(ListNode *nodePtr) const}
188 {
189 if (nodePtr != nullptr)
190
1 9 1
192 cout << nodePtr->value << " ";
1 9 3
    }
194 }
```

The base case for the function is nodePtr being set to nullptr. When this is true, the function has reached the last node in the list, so it returns. It is not until this happens that any instances of the cout statement execute. The instance of the function whose nodePtr variable points to the last node in the list will be the first to execute the cout statement. It will then return, and the previous instance of the function will execute its cout statement. This repeats until all the instances of the function have returned.

The modified class declaration is stored in NumberList.h, and its member function implementation is in NumberList.cpp. The remainder of the class implementation is unchanged from Chapter 18, so it is not shown here. Program 20-8 demonstrates the function.

## Program 20-8

```
// This program demonstrates the recursive function
// for displaying the list's nodes in reverse.
#include <iostream>
#include "NumberList.h"
using namespace std;
int main()
{
    const double MAX = 10.0; // Upper 1imit of values
    // Create a NumberList object.
    NumberList list;
    // Add a series of numbers to the list.
    for (double x = 1.5; x < MAX; x += 1.1)
            1ist.appendNode(x);
    // Display the values in the list.
    cout << "Here are the values in the list:\n";
    1ist.displayList();
    // Display the values in reverse order.
    cout << "Here are the values in reverse order:\n";
    1ist.displayBackwards();
    return 0;
}
```

## Program Output

Here are the values in the list:
1.5
2.6
3.7
4.8
5.9

7
8.1
9.2

Here are the values in reverse order:
9.28 .175 .94 .83 .72 .61 .5

### 20.6 Focus on Problem Solving and Program Design: A Recursive Binary Search Function

CONCEPT: The binary search algorithm can be defined as a recursive function.
In Chapter 8, you learned about the binary search algorithm and saw an iterative example written in C++. The binary search algorithm can also be implemented recursively. For example, the procedure can be expressed as

```
If array[middle] equals the search value, then the value is found.
Else, if array[middle] is less than the search value, perform a
binary search on the upper half of the array.
Else, if array[middle] is greater than the search value, perform a
binary search on the lower half of the array.
```

The recursive binary search algorithm is an example of breaking a problem down into smaller pieces until it is solved. A recursive binary search function is shown here:

```
int binarySearch(int array[], int first, int last, int value)
{
    int middle; // Midpoint of search
    if (first > last)
        return -1;
    middle = (first + last) / 2;
    if (array[middle] == value)
        return middle;
    if (array[middle] < value)
        return binarySearch(array, middle+1,1ast,value);
    else
        return binarySearch(array, first,middle-1,value);
}
```

The first parameter, array, is the array to be searched. The next parameter, first, holds the subscript of the first element in the search range (the portion of the array to be searched). The next parameter, last, holds the subscript of the last element in the search range. The last parameter, value, holds the value to be searched for. Like the iterative version, this function returns the subscript of the value if it is found, or -1 if the value is not found. Program 20-9 demonstrates the function.

## Program 20-9

```
// This program demonstrates the recursive binarySearch function.
#include <iostream>
using namespace std;
// Function prototype
int binarySearch(int [], int, int, int);
const int SIZE = 20; // Array size
int main()
{
    // Define an array of employee ID numbers
    int tests[SIZE] = {101, 142, 147, 189, 199, 207, 222,
                                    234, 289, 296, 310, 319, 388, 394,
                                    417, 429, 447, 521, 536, 600};
    int empID; // To hold an ID number
    int results; // To hold the search results
    // Get an employee ID number to search for.
    cout << "Enter the Employee ID you wish to search for: ";
    cin >> empID;
    // Search for the ID number in the array.
    results = binarySearch(tests, 0, SIZE - 1, empID);
    // Display the results of the search.
    if (results == -1)
        cout << "That number does not exist in the array.\n";
    else
    {
        cout << "That ID is found at element " << results;
        cout << " in the array\n";
    }
    return 0;
}
//****************************************************************
// The binarySearch function performs a recursive binary search *
// on a range of elements of an integer array passed into the
// parameter array. The parameter first holds the subscript of
// the range's starting element, and last holds the subscript
// of the range's last element. The parameter value holds the *
// search value. If the search value is found, its array *
// subscript is returned. Otherwise, -1 is returned indicating *
// the value was not in the array.
//*******************************************************************
int binarySearch(int array[], int first, int last, int value)
{
    int middle; // Midpoint of search
    if (first > last)
            return -1;
    middle = (first + last)/2;
```

```
55
    if (array[middle]==value)
56 return middle;
57
    if (array[middle]<value)
        return binarySearch(array, middle+1,last,value);
    else
        return binarySearch(array, first,middle-1,value);
}
```

## Program Output with Example Input Shown in Bold

Enter the Employee ID you wish to search for: 521 Enter
That ID is found at element 17 in the array

### 20.7 The Towers of Hanoi

CONCEPT: The repetitive steps involved in solving the Towers of Hanoi game can be easily implemented in a recursive algorithm.

The Towers of Hanoi is a mathematical game often used in computer science textbooks to illustrate the power of recursion. The game uses three pegs and a set of discs with holes through their centers. The discs are stacked on one of the pegs as shown in Figure 20-4.

Figure 20-4 The pegs and discs in the Towers of Hanoi game

Notice the discs are stacked on the leftmost peg, in order of size with the largest disc at the bottom. The game is based on a legend in which a group of monks in a temple in Hanoi have a similar set of pegs with 64 discs. The job of the monks is to move the discs from the first peg to the third peg. The middle peg can be used as a temporary holder. Furthermore, the monks must follow these rules while moving the discs:

- Only one disc may be moved at a time.
- A disc cannot be placed on top of a smaller disc.
- All discs must be stored on a peg except while being moved.

According to the legend, when the monks have moved all of the discs from the first peg to the last peg, the world will come to an end.

To play the game, you must move all of the discs from the first peg to the third peg, following the same rules as the monks. Let's look at some example solutions to this game, for different numbers of discs. If you only have one disc, the solution to the game is simple: move the disc from peg 1 to peg 3. If you have two discs, the solution requires three moves:

- Move disc 1 to peg 2.
- Move disc 2 to peg 3.
- Move disc 1 to peg 3.

Notice this approach uses peg 2 as a temporary location. The complexity of the moves continues to increase as the number of discs increases. To move three discs requires the seven moves shown in Figure 20-5.

Figure 20-5 Moving three discs

Second move: Move disc 2 to peg 2.

Fourth move: Move disc 3 to peg 3.

Third move: Move disc 1 to peg 2.

Fifth move: Move disc 1 to peg 1.

Sixth move: Move disc 2 to peg 3.

Seventh move: Move disc 1 to peg 3.

The following statement describes the overall solution to the problem:
Move $n$ discs from peg 1 to peg 3 using peg 2 as a temporary peg.
The following pseudocode algorithm can be used as the basis of a recursive function that simulates the solution to the game. Notice in this algorithm we use the variables $A, B$, and $C$ to hold peg numbers.

To move $n$ discs from peg $A$ to peg $C$, using peg $B$ as a temporary peg
If $n>0$ Then
Move n-1 discs from peg A to peg B, using peg C as a temporary peg
Move the remaining disc from the peg A to peg C
Move n-1 discs from peg B to peg C, using peg A as a temporary peg
End If
The base case for the algorithm is reached when there are no more discs to move. The following code is for a function that implements this algorithm. Note the function does not actually move anything, but displays instructions indicating all of the disc moves to make.

```
void moveDiscs(int num, int fromPeg, int toPeg, int tempPeg)
{
    if (num > 0)
    {
        moveDiscs(num - 1, fromPeg, tempPeg, toPeg);
        cout << "Move a disc from peg " << fromPeg
            << " to peg " << toPeg << endl;
        moveDiscs(num - 1, tempPeg, toPeg, fromPeg);
    }
}
```

This function accepts arguments into the following three parameters:

```
num The number of discs to move.
fromPeg The peg from which to move the discs.
toPeg The peg to which to move the discs.
tempPeg The peg to use as a temporary peg.
```

If num is greater than 0 , then there are discs to move. The first recursive call is

```
moveDiscs(num - 1, fromPeg, tempPeg, toPeg);
```

This statement is an instruction to move all but one disc from fromPeg to tempPeg, using toPeg as a temporary peg. The next statement is

```
cout << "Move a disc from peg " << fromPeg
    << " to peg " << toPeg << endl;
```

This simply displays a message indicating that a disc should be moved from fromPeg to toPeg. Next, another recursive call is executed:

```
moveDiscs(num - 1, tempPeg, toPeg, fromPeg);
```

This statement is an instruction to move all but one disc from tempPeg to toPeg, using fromPeg as a temporary peg. Program 20-10 demonstrates this function.

## Program 20-10

```
// This program displays a solution to the Towers of
// Hanoi game.
#include <iostream>
using namespace std;
// Function prototype
void moveDiscs(int, int, int, int);
int main()
{
    const int NUM_DISCS = 3; // Number of discs to move
    const int FROM_PEG = 1; // Initial "from" peg
    const int TO_PEG = 3; // Initial "to" peg
    const int TEMP_PEG = 2; // Initial "temp" peg
    // Play the game.
    moveDiscs(NUM_DISCS, FROM_PEG, TO_PEG, TEMP_PEG);
    cout << "All the pegs are moved!\n";
```

```
Program 20-10 (continued)
19 return 0;
20 }
2 1
//*****************************************************
// The moveDiscs function displays a disc move in *
// the Towers of Hanoi game.
// The parameters are:
// num: The number of discs to move. *
// fromPeg: The peg to move from. *
// toPeg: The peg to move to. *
// tempPeg: The temporary peg. *
//****************************************************
void moveDiscs(int num, int fromPeg, int toPeg, int tempPeg)
{
    if (num > 0)
    {
        moveDiscs(num - 1, fromPeg, tempPeg, toPeg);
        cout << "Move a disc from peg " << fromPeg
                    << " to peg " << toPeg << endl;
        moveDiscs(num - 1, tempPeg, toPeg, fromPeg);
    }
}
```

## Program Output

Move a disc from peg 1 to peg 3
Move a disc from peg 1 to peg 2
Move a disc from peg 3 to peg 2
Move a disc from peg 1 to peg 3
Move a disc from peg 2 to peg 1
Move a disc from peg 2 to peg 3
Move a disc from peg 1 to peg 3
All the pegs are moved!

### 20.8 Focus on Problem Solving and Program Design: The QuickSort Algorithm

CONCEPT: The QuickSort algorithm uses recursion to efficiently sort a list.
The QuickSort algorithm is a popular general-purpose sorting routine developed in 1960 by C.A.R. Hoare. It can be used to sort lists stored in arrays or linear linked lists. It sorts a list by dividing it into two sublists. Between the sublists is a selected value known as the pivot. This is illustrated in Figure 20-6.

Notice in the figure sublist 1 is positioned to the left of (before) the pivot, and sublist 2 is positioned to the right of (after) the pivot. Once a pivot value has been selected, the algorithm exchanges the other values in the list until all the elements in sublist 1 are less than the pivot, and all the elements in sublist 2 are greater than the pivot.

Figure 20-6 A partitioned data set

Once this is done, the algorithm repeats the procedure on sublist 1 , then on sublist 2 . The recursion stops when there is only one element in a sublist. At that point, the original list is completely sorted.
The algorithm is coded primarily in two functions: quickSort and partition. quickSort is a recursive function. Its pseudocode is shown here:

```
quickSort:
If Starting Index < Ending Index
    Partition the List around a Pivot
    quickSort Sublist 1
    quickSort Sublist 2
End If
```

Here is the C++ code for the quickSort function:

```
void quickSort(int set[], int start, int end)
{
    int pivotPoint;
    if (start < end)
    {
        // Get the pivot point.
        pivotPoint = partition(set, start, end);
        // Sort the first sublist.
        quickSort(set, start, pivotPoint - 1);
        // Sort the second sublist.
        quickSort(set, pivotPoint + 1, end);
    }
}
```

This version of quickSort works with an array of integers. Its first argument is the array holding the list that is to be sorted. The second and third arguments are the starting and ending subscripts of the list.

The subscript of the pivot element is returned by the partition function. partition not only determines which element will be the pivot, but also controls the rearranging of the other values in the list. Our version of this function selects the element in the middle of the list as the pivot, then scans the remainder of the list searching for values less than the pivot.
The code for the partition function is shown here:

```
int partition(int set[], int start, int end)
{
    int pivotValue, pivotIndex, mid;
    mid = (start + end) / 2;
    swap(set[start], set[mid]);
    pivotIndex = start;
    pivotValue = set[start];
```

```
    for (int scan = start + 1; scan <= end; scan++)
    {
        if (set[scan] < pivotValue)
        {
            pivotIndex++;
                swap(set[pivotIndex], set[scan]);
        }
    }
    swap(set[start], set[pivotIndex]);
    return pivotIndex;
}
```

NOTE: The partition function does not initially sort the values into their final order. Its job is only to move the values that are less than the pivot to the pivot's left, and move the values that are greater than the pivot to the pivot's right. As long as that condition is met, they may appear in any order. The ultimate sorting order of the entire list is achieved cumulatively, though the recursive calls to quickSort.

There are many different ways of partitioning the list. As previously stated, the method shown in the function above selects the middle value as the pivot. That value is then moved to the beginning of the list (by exchanging it with the value stored there). This simplifies the next step, which is to scan the list.

A for loop scans the remainder of the list, and when an element is found whose value is less than the pivot, that value is moved to a location left of the pivot point.

A third function, swap, is used to swap the values found in any two elements of the list. The function is shown below:

```
void swap(int &value1, int &value2)
{
    int temp = value1;
    value1 = value2;
    value2 = temp;
}
```

Program 20-11 demonstrates the QuickSort algorithm.

## Program 20-11

```
// This program demonstrates the QuickSort Algorithm.
#include <iostream>
using namespace std;
// Function prototypes
void quickSort(int [], int, int);
int partition(int [], int, int);
void swap(int &, int &);
int main()
{
    const int SIZE = 10; // Array size
    int count; // Loop counter
    int array[SIZE] = {7, 3, 9, 2, 0, 1, 8, 4, 6, 5};
```

```
    // Display the array contents.
    for (count = 0; count < SIZE; count++)
        cout << array[count] << " ";
    cout << endl;
    // Sort the array.
    quickSort(array, 0, SIZE - 1);
    // Display the array contents.
    for (count = 0; count < SIZE; count++)
        cout << array[count] << " ";
    cout << endl;
    return 0;
}

### 20.9 Exhaustive Algorithms

CONCEPT: An exhaustive algorithm is one that finds a best combination of items by looking at all the possible combinations.

Recursion is helpful if you need to examine many possible combinations and identify the best combination. For example, consider all the different ways you can make change for $\$ 1.00$ using our system of coins:
1 dollar piece, or
2 fifty-cent pieces, or
4 quarters, or
1 fifty-cent piece and 2 quarters, or
3 quarters, 2 dimes, and 1 nickel, or
... there are many more possibilities.
Although there are many ways to make change for $\$ 1.00$, some ways are better than others. For example, you would probably rather give a single dollar piece instead of 100 pennies.
An algorithm that looks at all the possible combinations of items in order to find the best combination of items is called an exhaustive algorithm. Program 20-12 presents a recursive function that exhaustively tries all the possible combinations of coins. The program then displays the total number of combinations that can be used to make the specified change, and the best combination of coins.

## Program 20-12

```
// This program demonstrates a recursive function that exhaustively
// searches through all possible combinations of coin values to find
// the best way to make change for a specified amount.
#include <iostream>
using namespace std;
// Constants
const int MAX_COINS_CHANGE = 100; // Max number of coins to give in change
const int MAX_COIN_VALUES = 6; // Max number of coin values
const int NO_SOLUTION = INT_MAX; // Indicates no solution
// Function prototype
void makeChange(int, int, int[], int);
// coinValues - global array of coin values to choose from
int coinValues[MAX_COIN_VALUES] = {100, 50, 25, 10, 5, 1 };
// bestCoins - global array of best coins to make change with
int bestCoins[MAX_COINS_CHANGE];
// G1obal variables
int numBestCoins = NO_SOLUTION, // Number of coins in bestCoins
    numSolutions = 0, // Number of ways to make change
    numCoins; // Number of allowable coins
int main()
    int coinsUsed[MAX_COINS_CHANGE], // List of coins used
    numCoinsUsed = 0, // The number of coins used
    amount; // The amount to make change for
    // Display the possible coin values.
    cout << "Here are the valid coin values, in cents: ";
    for (int index = 0; index < 5; index++)
        cout << coinValues[index] << " ";
    cout << endl;
    // Get input from the user.
    cout << "Enter the amount of cents (as an integer) "
        << "to make change for: ";
    cin >> amount;
    cout << "What is the maximum number of coins to give as change? ";
    cin >> numCoins;
    // Cal1 the recursive function.
    makeChange(numCoins, amount, coinsUsed, numCoinsUsed);
    // Display the results.
    cout << "Number of possible combinations: " << numSolutions << endl;
    cout << "Best combination of coins:\n";
    if (numBestCoins == NO_SOLUTION)
        cout << "\tNo solution\n";
```

## Program 20-12 (continued)

```
    else
    {
        for (int count = 0; count < numBestCoins; count++)
            cout << bestCoins[count] << " ";
        }
        cout << endl;
        return 0;
}
|/***************************************************************************
// Function makeChange. This function uses the following parameters:
// coinsLeft - The number of coins left to choose from.
// amount - The amount to make change for.
// coinsUsed - An array that contains the coin values used so far.
// numCoinsUsed - The number of values in the coinsUsed array.
//
// This recursive function finds all the possible ways to make change *
// for the value in amount. The best combination of coins is stored in *
// the array bestCoins.
//************************************************************************
void makeChange(int coinsLeft, int amount, int coinsUsed[],
                int numCoinsUsed)
{
    int coinPos, // To calculate array position of coin being used
    count; // Loop counter
    if (coinsLeft == 0) // If no more coins are left
        return;
    else if (amount < 0) // If amount to make change for is negative
        return;
    else if (amount == 0) // If solution is found
    {
        // Store as bestCoins if best
        if (numCoinsUsed < numBestCoins)
        {
            for (count = O; count < numCoinsUsed; count++)
                bestCoins[count] = coinsUsed[count];
            numBestCoins = numCoinsUsed;
        }
        numSolutions++;
        return;
    }
    // Find the other combinations using the coin
    coinPos = numCoins - coinsLeft;
    coinsUsed[numCoinsUsed] = coinValues[coinPos];
    numCoinsUsed++;
    makeChange(coinsLeft, amount - coinValues[coinPos],
                        coinsUsed, numCoinsUsed);
    // Find the other combinations not using the coin.
    numCoinsUsed--;
    makeChange(coinsLeft - 1, amount, coinsUsed, numCoinsUsed);
}
```

```
Program Output with Example Input Shown in Bold
Here are the valid coin values, in cents: 100 50 25 10 5 1
Enter the amount of cents (as an integer) to make change for: 62 Enter
What is the maximum number of coins to give as change? 6 Enter)
Number of possible combinations: 77
Best combination of coins:
50 10 1 1
```

### 20.10 Focus on Software Engineering: Recursion versus Iteration

CONCEPT: Recursive algorithms can also be coded with iterative control structures. There are advantages and disadvantages to each approach.

Any algorithm that can be coded with recursion can also be coded with an iterative control structure, such as a while loop. Both approaches achieve repetition, but which is best to use?
There are several reasons not to use recursion. Recursive algorithms are certainly less efficient than iterative algorithms. Each time a function is called, the system incurs overhead that is not necessary with a loop. Also, in many cases an iterative solution may be more evident than a recursive one. In fact, the majority of repetitive programming tasks are best done with loops.

Some problems, however, are more easily solved with recursion than with iteration. For example, the mathematical definition of the GCD formula is well-suited for a recursive approach. The QuickSort algorithm is also an example of a function that is easier to code with recursion than iteration.

The speed and amount of memory available to modern computers diminishes the performance impact of recursion so much that inefficiency is no longer a strong argument against it. Today, the choice of recursion or iteration is primarily a design decision. If a problem is more easily solved with a loop, that should be the approach you take. If recursion results in a better design, that is the choice you should make.

## Review Questions and Exercises

## Short Answer

1. What is the base case of each of the recursive functions listed in Questions 12,13 , and 14?
2. What type of recursive function do you think would be more difficult to debug, one that uses direct recursion, or one that uses indirect recursion? Why?
3. Which repetition approach is less efficient, a loop or a recursive function? Why?
4. When should you choose a recursive algorithm over an iterative algorithm?
5. Explain what is likely to happen when a recursive function that has no way of stopping executes.

## Fill-in-the-Blank

6. The $\qquad$ of recursion is the number of times a function calls itself.
7. A recursive function's solvable problem is known as its $\qquad$ This causes the recursion to stop.
8. $\qquad$ recursion is when a function explicitly calls itself.
9. $\qquad$ recursion is when function A calls function B , which in turns calls function A .

## Algorithm Workbench

10. Declare a node of a singly linked list such that each node stores a number. Write a recursive function to find the sum of the numbers in the linked list.
11. Write a recursive function to print the first odd numbers up to $n$ in reverse order.

## Predict the Output

What is the output of the following programs?

```
12. #include <iostream>
    using namespace std;
    int function(int);
    int main()
    {
        int x = 10;
        cout << function(x) << endl;
        return 0;
    }
    int function(int num)
    {
        if (num <= 0)
            return 0;
        else
            return function(num - 1) + num;
    }
13. #include <iostream>
    #include <iomanip>
    using namespace std;
    void pattern(int, int);
    int main()
    {
        function(5,1);
        return 0;
    }
    void pattern(int row, int num)
    {
        if (row > 0)
        {
            for (int i = 0; i < row; i++)
                cout << setw(3) << num++;
                cout << endl;
                function(row - 1, num);
        }
    }
```

```
14. #include <iostream>
using namespace std;
void hello(int);
int main()
{
    he11o(1);
    cout << "Good Bye!" << endl;
    return 0;
}
void hello(int n)
{
    int response;
    cout << "Hello!" << endl;
    cout << "You are wished" << n << "times." << endl;
    cout << "Press Y to be wished again. . .";
    cin >> response;
    if ( response =='y' || response =='Y')
        he11o(n+1);
}
```

## Programming Challenges

## 1. Iterative Function for Character Count

Write an iterative version (using loop) of the recursive function shown in this chapter to count the number of times a character appears in a string. Test with a driver program.

## 2. Recursive Conversion

Convert the following function to one that uses recursion:

```
void doAgain()
{ char answer;
    do { cout << "Executing function. Press Y to execute again.";
        cin >> answer;
    } while ( answer == 'y' || answer == 'Y' );
}
```

Demonstrate the function with a driver program.

## 3. QuickSort Template

Create a template version of the QuickSort algorithm that will work with any data type. Demonstrate the template with a driver function.

## 4. Print Reverse Array

Write a recursive function that accepts a numeric array and a number indicating the number of array elements as arguments. The function should display the array in reverse order. Demonstrate the function in a program.

## 5. Recursive Multiplication`

Write a recursive function that accepts two arguments into the parameters $x$ and $y$. The function should return the value of $x$ times $y$. Remember, multiplication can be performed as repeated addition:

```
7 * 4 = 4 + 4 + 4 + 4 + 4 + 4 + 4
```

## 6. Highest Common Factor

Write a recursive function that finds the highest common factor (H.C.F.) of two numbers. The function should accept two numbers as arguments and return their H.C.F. Demonstrate the function in a program.

## 7. Sum of Odd Numbers

Write a function that accepts two integer arguments and returns the sum of all the odd integers in between the two numbers. For example, if 20 and 50 are passed as arguments, the function will return the sum of $21,23,25, \ldots, 49$. Use recursion to calculate the sum. Demonstrate the function in a program.

## 8. Arithmetic Progression Series

In an arithmetic progression (A.P.) series, each element can be calculated by adding a fixed number (called the common difference) to the previous element. Write a recursive function that prints an A.P. series. The function should accept the first term, the common difference, and the number of terms as arguments. Test with a driver program.

## 9. String Reverser

Write a recursive function that accepts a string object as its argument and prints the string in reverse order. Demonstrate the function in a driver program.

## 10. maxNode Function

Add a member function named maxNode to the NumberList class discussed in this chapter. The function should return the largest value stored in the list. Use recursion in the function to traverse the list. Demonstrate the function in a driver program.

## 11. Palindrome Detector

A palindrome is any word, phrase, or sentence that reads the same forward and backward. Here are some well-known palindromes:

Able was I, ere I saw Elba
A man, a plan, a canal, Panama
Desserts, I stressed
Kayak
Write a bool function that uses recursion to determine if a string argument is a palindrome. The function should return true if the argument reads the same forward and backward. Demonstrate the function in a program.

## 12. Ackermann's Function

Ackermann's Function is a recursive mathematical algorithm that can be used to test how well a computer performs recursion. Write a function $A(m, n)$ that solves Ackermann's Function. Use the following logic in your function:

```
If m = 0 then return n + 1
If n = 0 then return A(m-1, 1)
Otherwise, return A(m-1, A(m, n-1))
```

Test your function in a driver program that displays the following values:

$$
A(0,0) A(0,1) A(1,1) A(1,2) A(1,3) A(2,2) A(3,2)
$$

## ER CHAPTER 1 Binary Trees

TOPICS
$\begin{array}{ll}\text { 21.1 } & \text { Definition and Applications of } \\ \text { Binary Trees } \\ \text { 21.2 } & \text { Binary Search Tree Operations }\end{array}$
21.3 Template Considerations for Binary Search Trees

### 21.1 Definition and Applications of Binary Trees

CONCEPT: A binary tree is a nonlinear linked structure in which each node may point to two other nodes, and every node but the root node has a single predecessor. Binary trees expedite the process of searching large sets of data.

A standard linked list is a linear data structure in which one node is linked to the next. A binary tree is a nonlinear linked structure. It is nonlinear because each node can point to two other nodes. Figure 21-1 illustrates the organization of a binary tree.

The data structure is called a tree because it resembles an upside-down tree. It is anchored at the top by a tree pointer, which is like the head pointer in a standard linked list. The first node in the list is called the root node. The root node has pointers to two other nodes, which are called children, or child nodes. Each of the children has its own set of two pointers, and can have its own children. Notice not all nodes have two children. Some point to only one node, and some point to no other nodes. A node with no children is called a leaf node. All pointers that do not point to a node are set to nullptr.

Figure 21-1 A binary tree

Binary trees can be divided into subtrees. A subtree is an entire branch of the tree, from one particular node down. For example, Figure 21-2 shows the left subtree from the root node of the tree shown in Figure 21-1.

Figure 21-2 Left subtree

## Applications of Binary Trees

Searching any linear data structure, such as an array or a standard linked list, is slow when the structure holds a large amount of data. This is because of the sequential nature of linear data structures. Binary trees are excellent data structures for searching large amounts of data. They are commonly used in database applications to organize key values that index database records. When used to facilitate searches, a binary tree is called a binary search tree. Binary search trees are the primary focus of this chapter.
Data are stored in binary search trees in a way that makes a binary search simple. For example, look at Figure 21-3.

Figure 21-3 A binary tree storing letters of the alphabet

The figure depicts a binary search tree where each node stores a letter of the alphabet. Notice the root node holds the letter M. The left child of the root node holds the letter F, and the right child holds R. Values are stored in a binary search tree so a node's left child holds data whose value is less than the node's data, and the node's right child holds data whose value is greater than the node's data. This is true for all nodes in the tree that have children.
It is also true that all the nodes to the left of a node hold values less than the node's value. Likewise, all the nodes to the right of a node hold values that are greater than the node's data. When an application is searching a binary tree, it starts at the root node. If the root node does not hold the search value, the application branches either to the left or right child, depending on whether the search value is less than or greater than the value at the root node. This process continues until the value is found. Figure 21-4 illustrates the search pattern for finding the letter P in the binary tree shown.

Figure 21-4 Search pattern for finding the letter $P$

## (1) Checkpoint

21.1 Describe the difference between a binary tree and a standard linked list.
21.2 What is a root node?
21.3 What is a child node?
21.4 What is a leaf node?
21.5 What is a subtree?
21.6 Why are binary trees suitable for algorithms that must search large amounts of data?

### 21.2 Binary Search Tree Operations

CONCEPT: Many operations may be performed on a binary search tree. In this section, we will discuss creating a binary search tree and inserting, finding, and deleting nodes.

In this section, you will learn some basic operations that may be performed on a binary search tree. We will study a simple class that implements a binary tree for storing integer values.

## Creating a Binary Tree

We will demonstrate the fundamental binary tree operations using a simple ADT: the IntBinaryTree class. The basis of our binary tree node is the following struct declaration:

```
struct TreeNode
{
    int value;
    TreeNode *1eft;
    TreeNode *right;
};
```

Each node has a value member for storing its integer data, as well as left and right pointers. The struct is implemented in the class declaration shown here:

## Contents of IntBinaryTree.h

```
// Specification file for the IntBinaryTree class
#ifndef INTBINARYTREE_H
#define INTBINARYTREE_H
class IntBinaryTree
{
private:
    struct TreeNode
    {
        int value; // The value in the node
        TreeNode *left; // Pointer to left child node
        TreeNode *right; // Pointer to right child node
    };
    TreeNode *root; // Pointer to the root node
    // Private member functions
    void insert(TreeNode *&, TreeNode *&);
    void destroySubTree(TreeNode *);
    void deleteNode(int, TreeNode *&);
    void makeDeletion(TreeNode *&);
    void displayInOrder(TreeNode *) const;
    void displayPreOrder(TreeNode *) const;
    void displayPostOrder(TreeNode *) const;
public:
    // Constructor
    IntBinaryTree()
            { root = nullptr; }
        // Destructor
        ~IntBinaryTree()
            { destroySubTree(root); }
        // Binary tree operations
        void insertNode(int);
        bool searchNode(int);
        void remove(int);
```

```
            void displayInOrder() const
            { displayInOrder(root); }
            void displayPreOrder() const
            { displayPreOrder(root); }
            void displayPostOrder() const
            { displayPostOrder(root); }
};
#endif
```

The root pointer will be used as the tree pointer. Similar to the head pointer in a linked list, root will point to the first node in the tree, or to nullptr if the tree is empty. It is initialized in the constructor, which is declared inline. The destructor calls destroySubTree, a private member function that recursively deletes all the nodes in the tree.

## Inserting a Node

The code to insert a node into the tree is fairly straightforward. The public member function insertNode is called with the number to be inserted passed as an argument. The code for the function, which is in IntBinaryTree.cpp, is shown here:

```
void IntBinaryTree::insertNode(int num)
{
    TreeNode *newNode = nullptr; // Pointer to a new node.
    // Create a new node and store num in it.
    newNode = new TreeNode;
    newNode->value = num;
    newNode->left = newNode->right = nullptr;
    // Insert the node.
    insert(root, newNode);
}
```

First, a new node is allocated in line 32 and its address stored in the local pointer variable newNode. The value passed as an argument is stored in the node's value member in line 33. The node's left and right child pointers are set to nullptr in line 34 because all nodes must be inserted as leaf nodes. Next, the private member function insert is called in line 37. Notice the root pointer and the newNode pointer are passed as arguments. The code for the insert function is shown here:

```
1 2 \text { void IntBinaryTree::insert(TreeNode *\&nodePtr, TreeNode *\&newNode)}
13 {
14 if (nodePtr == nullptr)
    nodePtr = newNode; // Insert the node.
    else if (newNode->value < nodePtr->value)
    insert(nodePtr->left, newNode); // Search the left branch.
    else
            insert(nodePtr->right, newNode); // Search the right branch.
        }
```

In general, this function takes a pointer to a subtree, and a pointer to a new node as arguments. It searches for the appropriate location in the subtree to insert the node, then makes the insertion. Notice the declaration of the first parameter, nodePtr:

## TreeNode *\&nodePtr

The nodePtr parameter is not simply a pointer to a TreeNode structure, but a reference to a pointer to a TreeNode structure. This means that any action performed on nodePtr is actually performed on the argument that was passed into nodePtr. The reason for this will be explained momentarily.

The if statement in line 14 determines whether nodePtr is set to nullptr:

```
if (nodePtr == nullptr)
    nodePtr = newNode; // Insert the node.
```

If nodePtr is set to nullptr, it is at the end of a branch, and the insertion point has been found. nodePtr is then made to point to newNode, which inserts newNode into the tree. This is why the nodePtr parameter is a reference. If it weren't a reference, this function would be making a copy of a node point to the new node, not the actual node in the tree.

If nodePtr is not set to nullptr, the following else if statement in line 16 executes:

```
else if (newNode->value < nodePtr->value)
    insert(nodePtr->left, newNode); // Search the left branch.
```

If the new node's value is less than the value pointed to by nodePtr, the insertion point is somewhere in the left subtree. If this is the case, the insert function is recursively called in line 17 with nodePtr $\rightarrow$ left passed as the subtree argument.

If the new node's value is not less than the value pointed to by nodePtr, the el se statement in line 18 executes:

```
else
    insert(nodePtr->right, newNode); // Search the right branch.
```

The else statement recursively calls the insert function called with nodePtr->right passed as the subtree argument.
Program 21-1 demonstrates these functions.

## Program 21-1

```
// This program builds a binary tree with 5 nodes.
#include <iostream>
#include "IntBinaryTree.h"
using namespace std;
int main()
{
    IntBinaryTree tree;
    cout << "Inserting nodes. ";
    tree.insertNode(5);
    tree.insertNode(8);
    tree.insertNode(3);
    tree.insertNode(12);
    tree.insertNode(9);
    cout << "Done.ln";
    return 0;
}
```

Figure 21-5 shows the structure of the binary tree built by Program 21-1.
Figure 21-5 Binary tree built by Program 21-1

NOTE: The shape of the tree is determined by the order in which the values are inserted. The root node in the diagram above holds the value 5 because that was the first value inserted. By stepping through the function, you can see how the other nodes came to appear in their depicted positions.

NOTE: If the new value being inserted into the tree is equal to an existing value, the insertion algorithm inserts it to the right of the existing value.

## Traversing the Tree

There are three common methods for traversing a binary tree and processing the value of each node: inorder, preorder, and postorder. Each of these methods is best implemented as a recursive function. The algorithms are described as follows:

## - Inorder traversal

1. The current node's left subtree is traversed.
2. The current node's data is processed.
3. The current node's right subtree is traversed.

- Preorder traversal

1. The current node's data is processed
2. The current node's left subtree is traversed.
3. The current node's right subtree is traversed.

## - Postorder traversal

1. The current node's left subtree is traversed.
2. The current node's right subtree is traversed.
3. The current node's data is processed.

The IntBinaryTree class can display all the values in the tree using all three of these algorithms. The algorithms are initiated by the following inline public member functions:

```
void displayInOrder() const
    { displayInOrder(root); }
void displayPreOrder() const
    { displayPreOrder(root); }
void displayPostOrder() const
    { displayPostOrder(root); }
```

Each of the public member functions calls an overloaded recursive private member function and passes the root pointer as an argument. The recursive functions, which are very simple and straightforward, are shown here:

```
149 //
1 5 3
155 {
157
158
1 5 9
1 6 0
1 6 1
162
1 6 3
```

150 // The displayInOrder member function displays the values *

```
150 // The displayInOrder member function displays the values *
151 // in the subtree pointed to by nodePtr, via inorder traversal.*
151 // in the subtree pointed to by nodePtr, via inorder traversal.*
152 /|**************************************************************
152 /|**************************************************************
154 void IntBinaryTree::displayInOrder(TreeNode *nodePtr) const
154 void IntBinaryTree::displayInOrder(TreeNode *nodePtr) const
156 if (nodePtr)
156 if (nodePtr)
    if (nodePtr)
    if (nodePtr)
```

|/*************************************************************

```
|/*************************************************************
    {
    {
        displayInOrder(nodePtr->1eft);
        displayInOrder(nodePtr->1eft);
        cout << nodePtr->value << endl;
        cout << nodePtr->value << endl;
        displayInOrder(nodePtr->right);
        displayInOrder(nodePtr->right);
    }
    }
}
}
|/*************************************************************
|/*************************************************************
// The displayPreOrder member function displays the values
// The displayPreOrder member function displays the values
// in the subtree pointed to by nodePtr, via preorder traversal. *
// in the subtree pointed to by nodePtr, via preorder traversal. *
|/************************************************************
|/************************************************************
void IntBinaryTree::displayPreOrder(TreeNode *nodePtr) const
void IntBinaryTree::displayPreOrder(TreeNode *nodePtr) const
{
{
    {
    {
        cout << nodePtr->value << endl;
        cout << nodePtr->value << endl;
        displayPreOrder(nodePtr->left);
```

        displayPreOrder(nodePtr->left);
    ```
```

175
176
177
178
1 7 9
180 // The displayPostOrder member function displays the values
181 // in the subtree pointed to by nodePtr, via postorder traversal.
182
//***************************************************************
183
1 8 4 void IntBinaryTree::displayPostOrder(TreeNode *nodePtr) const
185 {
186 if (nodePtr)
187 {
188 disp1ayPostOrder(nodePtr->1eft);
1 8 9 ~ d i s p 1 a y P o s t O r d e r ( n o d e P t r - > r i g h t ) ;
190 cout << nodePtr->value << endl;
1 9 1
}
192 }

```

Program 21-2, which is a modification of Program 21-1, demonstrates each of the traversal methods.

\section*{Program 21-2}
```

// This program builds a binary tree with 5 nodes.
// The nodes are displayed with inorder, preorder,
// and postorder algorithms.
\#include <iostream>
\#include "IntBinaryTree.h"
using namespace std;
int main()
{
IntBinaryTree tree;
// Insert some nodes.
cout << "Inserting nodes.\n";
tree.insertNode(5);
tree.insertNode(8);
tree.insertNode(3);
tree.insertNode(12);
tree.insertNode(9);
// Display inorder.
cout << "Inorder traversal:\n";
tree.displayInOrder();
// Display preorder.
cout << "\nPreorder traversal:\n";
tree.displayPreOrder();
// Display postorder.
cout << "\nPostorder traversa1:\n";
tree.displayPostOrder();
return 0;
}

```
```

Program Output
Inserting nodes.
Inorder traversal:
3
5
8
9
12
Preorder traversal:
5
3
8
12
9
Postorder traversa1:
3
9
12
8
5

```

\section*{Searching the Tree}

The IntBinaryTree class has a public member function, searchNode, that returns true if a value is found in the tree, or false otherwise. The function simply starts at the root node and traverses the tree until it finds the search value or runs out of nodes. The code is shown here:
```

6 3 bool IntBinaryTree::searchNode(int num)
64 {
65 TreeNode *nodePtr = root;
66
67 while (nodePtr)
6 8
69
70
71
72
73
74
75
76 return false;
77 }

```

Program 21-3 demonstrates this function.

\section*{Program 21-3}
```

// This program builds a binary tree with 5 nodes.
// The SearchNode function is demonstrated.
\#include <iostream>
\#include "IntBinaryTree.h"
using namespace std;
int main()
{
IntBinaryTree tree;
// Insert some nodes in the tree.
cout << "Inserting nodes.\n";
tree.insertNode(5);
tree.insertNode(8);
tree.insertNode(3);
tree.insertNode(12);
tree.insertNode(9);
// Search for the value 3.
if (tree.searchNode(3))
cout << "3 is found in the tree.\n";
else
cout << "3 was not found in the tree.\n";
// Search for the value 100.
if (tree.searchNode(100))
cout << "100 is found in the tree.\n";
else
cout << "100 was not found in the tree.\n";
return 0;
}

```

\section*{Program Output}

Inserting nodes.
3 is found in the tree.
100 was not found in the tree.

\section*{Deleting a Node}

Deleting a leaf node is not difficult. We simply find its parent and set the child pointer that links to it to nullptr, then free the node's memory. But what if we want to delete a node that has child nodes? We must delete the node while at the same time preserving the subtrees to which the node links.

There are two possible situations to face when deleting a nonleaf node: the node has one child, or the node has two children. Figure 21-6 illustrates a tree in which we are about to delete a node with one subtree.

Figure 21-6 A node with one subtree is about to be deleted

Figure 21-7 shows how we will link the node's subtree with its parent.

Figure 21-7 Linking the parent node with the subtree

The problem is not as easily solved, however, when the node we are about to delete has two subtrees. For example, look at Figure 21-8:

Figure 21-8 A node with two subtrees is about to be deleted

Obviously, we cannot attach both of the node's subtrees to its parent, so there must be an alternative solution. One way of addressing this problem is to attach the node's right subtree to the parent, then find a position in the right subtree to attach the left subtree. The result is shown in Figure 21-9.

Figure 21-9 Relinking the subtrees

Now we will see how this action is implemented in code. To delete a node from the IntBinaryTree, call the public member remove. The argument passed to the function is the value of the node you wish to delete. The remove member function is shown here:
```

84 void IntBinaryTree::remove(int num)
85 {
86 deleteNode(num, root);
87 }

```

The remove member function calls the deleteNode member function. It passes the value of the node to delete and the root pointer. The deleteNode member function is shown here:
```

void IntBinaryTree::deleteNode(int num, TreeNode *\&nodePtr)
{
if (num < nodePtr->value)
deleteNode(num, nodePtr->1eft);
else if (num > nodePtr->value)
deleteNode(num, nodePtr->right);
else
makeDeletion(nodePtr);
}

```

Notice this function's arguments are references to pointers. Like the insert function, the deleteNode function must have access to an actual pointer in the tree. You will see why momentarily.

The deleteNode function uses an if/else if statement. The first part of the statement is in lines 97 and 98:
```

if (num < nodePtr->value)
deleteNode(num, nodePtr->1eft);

```

This code compares the parameter num with the value member of the node to which nodePtr points. If num is less, then the value being searched for will appear somewhere in nodePtr's left subtree (if it appears in the tree at all). In this case, the deleteNode function is recursively called with num as the first argument, and nodePtr \(\rightarrow>1\) eft as the second argument.

If num is not less than nodePtr->value, the else if in lines 99 and 100 statement is executed:
```

else if (num > nodePtr->value)
deleteNode(num, nodePtr->right);

```

If num is greater than nodePtr->value, then the value being searched for will appear somewhere in nodePtr's right subtree (if it appears in the tree at all). So, the deleteNode function is recursively called with num as the first argument, and nodePtr \(->\) right as the second argument.

If num is equal to nodePtr \(->\) value, then neither of the if statements will find a true condition. In this case, nodePtr points to the node that is to be deleted, and the trailing else in lines 101 and 102 will execute:
```

else
makeDeletion(nodePtr);

```

The trailing else statement calls the makeDeletion function and passes nodePtr as its argument. The makeDeletion function actually deletes the node from the tree and must reattach the deleted node's subtrees as shown in Figure 21-9. Therefore, it must have access to the actual pointer, in the binary tree, to the node that is being deleted (not just a copy of the pointer). This is why the nodePtr parameter in the deleteNode function is a reference. It must pass to makeDeletion the actual pointer, in the binary tree, to the node that is to be deleted. The makeDe1etion function's code is as follows:

112 void IntBinaryTree::makeDeletion(TreeNode *\&nodePtr)
113 \{
114 // Define a temporary pointer to use in reattaching
115 // the left subtree.
116 TreeNode *tempNodePtr = nullptr;
117
118 if (nodePtr == nullptr)
119 cout << "Cannot delete empty node. In";
120 else if (nodePtr->right == nullptr)
121 \{
122 tempNodePtr = nodePtr;
123 nodePtr = nodePtr->left; // Reattach the left child.
delete tempNodePtr;
\}
else if (nodePtr->left == nullptr)
\{
tempNodePtr \(=\) nodePtr;
nodePtr \(=\) nodePtr \(\rightarrow\) right; // Reattach the right child.
delete tempNodePtr;
\}
// If the node has two children.
else
\{
// Move one node to the right. tempNodePtr \(=\) nodePtr->right; // Go to the end left node. while (tempNodePtr->left)
tempNodePtr = tempNodePtr->1eft;
// Reattach the left subtree. tempNodePtr->1eft = nodePtr->1eft; tempNodePtr \(=\) nodePtr; // Reattach the right subtree. nodePtr \(=\) nodePtr->right; delete tempNodePtr;
\}
\}
Program 21-4 demonstrates these functions.

\section*{Program 21-4}
// This program builds a binary tree with 5 nodes.
// The deleteNode function is used to remove two of them.
\#include <iostream>
\#include "IntBinaryTree.h"
using namespace std;
int main()
\{
IntBinaryTree tree;
// Insert some values into the tree. cout << "Inserting nodes. In";
tree.insertNode(5);
tree.insertNode(8);
tree.insertNode(3);
tree.insertNode(12);
tree.insertNode(9) ;
// Display the values.
cout << "Here are the values in the tree: \(\backslash n\) ";
tree.displayInOrder();
// Delete the value 8.
cout << "Deleting 8... ln ";
tree. remove(8);
// Delete the value 12. cout << "Deleting 12... n "; tree. remove(12);
// Display the values.
cout << "Now, here are the nodes: \(1 \mathrm{n} " ;\)
tree.displayInOrder(); return 0;
\}

\section*{Program Output}

Inserting nodes.
Here are the values in the tree:
3

5
8
9
12
Deleting 8...
Deleting 12...
Now, here are the nodes:
3
5
9

21.11 Describe the steps taken in deleting a node with one child.
21.12 Describe the steps taken in deleting a node with two children.

\subsection*{21.3 Template Considerations for Binary Search Trees}

CONCEPT: Binary search trees may be implemented as templates, but any data types used with them must support the \(<,>\), and \(==\) operators.

When designing a binary tree template, remember any data types stored in the binary tree must support the \(<,>\), and \(==\) operators. If you use the tree to store class objects, these operators must be overridden.

The following code shows an example of a binary tree template. Program 21-5 demonstrates the template. It creates a binary tree that can hold strings, then prompts the user to enter a series of names that are inserted into the tree. The program then displays the contents of the tree using inorder traversal.

\section*{Program 21-5}
```

// This program demonstrates the BinaryTree class template.
// It builds a binary tree with 5 nodes.
\#include <iostream>
\#include "BinaryTree.h"
using namespace std;
const int NUM_NODES = 5;
int main()
{
string name;
// Create the binary tree.
BinaryTree<string> tree;
// Insert some names.
for (int count = 0; count < NUM_NODES; count++)
{
cout << "Enter a name: ";
getline(cin, name);
tree.insertNode(name);
}
// Display the values.
cout << "\nHere are the values in the tree:\n";
tree.displayInOrder();
return 0;
}

```
```

Program Output with Example Input Shown in Bold
Enter a name: David Enter
Enter a name: Geri Enter
Enter a name: Chris Enter
Enter a name: Samantha Enter
Enter a name: Anthony Enter
Here are the values in the tree:
Anthony
Chris
David
Geri
Samantha

```

\section*{Review Questions and Exercises}

\section*{Short Answer}
1. Each node in a binary tree may point to how many other nodes?
2. How many predecessors may each node other than the root node have?
3. What is a leaf node?
4. What is a subtree?
5. What is observed if a binary search tree is searched using the inorder traversal algorithm?
6. A binary search tree has \(\mathrm{M}, \mathrm{O}, \mathrm{D}, \mathrm{A}, \mathrm{B}, \mathrm{X}, \mathrm{Z}\), and H as its node values. Which nodes will be in its left subtree, if \(M\) is the root node?

\section*{Fill-in-the-Blank}
7. A node in a binary tree can have a maximum of \(\qquad\) children.
8. A binary tree node's left and right pointers point to the node's \(\qquad\) .
9. Both pointers of a leaf node are set to \(\qquad\) .
10. A(n) \(\qquad\) is an entire branch of the tree, from one particular node down.
11. The three common types of traversal with a binary tree are \(\qquad\) , \(\qquad\) and \(\qquad\) .

\section*{Algorithm Workbench}
12. Write a pseudocode algorithm for inserting a node in a tree.
13. Write a pseudocode algorithm for the inorder traversal.
14. Write a pseudocode algorithm for the preorder traversal.
15. Write a pseudocode algorithm for the postorder traversal.
16. Write a pseudocode algorithm for searching a tree for a specified value.
17. Suppose the following values are inserted into a binary tree, in the order given:
\[
12,7,9,10,22,24,30,18,3,14,20
\]

Draw a diagram of the resulting binary tree.
18. How would the values in the tree you sketched for Question 17 be displayed in an inorder traversal?
19. How would the values in the tree you sketched for Question 17 be displayed in a preorder traversal?
20. How would the values in the tree you sketched for Question 17 be displayed in a postorder traversal?

\section*{True or False}
21. T F A binary tree is a linear data structure.
22. T F Binary trees are efficient in searching for large sets of data.
23. T F If a node with both left and right subtrees is to be deleted, the left subtree should also be deleted.
24. T F The shape of a binary tree is determined by the order in which values are inserted.
25. T F In a postorder traversal, a node's data is processed after both its left and right subtrees have been visited.

\section*{Programming Challenges}

\section*{1. Binary Tree Template}

Write your own version of a class template that will create a binary tree that can hold values of any data type. Demonstrate the class with a driver program.

\section*{2. Node Counter}

Write a member function, for either the template you designed in Programming Challenge 1 or the IntBinaryTree class, that counts and returns the number of nodes in the tree. Demonstrate the function in a driver program.

\section*{3. Leaf Counter}

Write a member function, for either the template you designed in Programming Challenge 1 or the IntBinaryTree class, that counts and returns the number of leaf nodes in the tree. Demonstrate the function in a driver program.

\section*{4. Tree Height}

Write a member function, for either the template you designed in Programming Challenge 1 or the IntBinaryTree class, that returns the height of the tree. The height of the tree is the number of levels it contains. For example, the tree shown in Figure 21-10 has three levels.

Figure 21-10 A tree with three levels

Demonstrate the function in a driver program.

\section*{5. Tree Width}

Write a member function, for either the template you designed in Programming Challenge 1 or the IntBinaryTree class, that returns the width of the tree. The width of the tree is the largest number of nodes in the same level. Demonstrate the function in a driver program.

\section*{6. Tree Assignment Operators, Copy Constructors, and Move Constructors}

Design an overloaded copy assignment operator, a move assignment operator, a copy constructor, and a move constructor for either the template you designed in Programming Challenge 1 or the IntBinaryTree class. Demonstrate them in a driver program.

\section*{7. Queue Converter}

Write a program that stores a series of numbers in a binary tree. Then have the program insert the values into a queue in ascending order. Dequeue the values and display them on the screen to confirm that they were stored in the proper order.
8. Employee Tree

Design an EmployeeInfo class that holds the following employee information:
Employee ID Number: an integer
Employee Name: a string
Next, use the template you designed in Programming Challenge 1 (Binary Tree Template) to implement a binary tree whose nodes hold an instance of the EmployeeInfo class. The nodes should be sorted on the Employee ID number.

Test the binary tree by inserting nodes with the following information.
\begin{tabular}{ll}
\hline \begin{tabular}{l} 
Employee \\
ID Number
\end{tabular} & Name \\
\hline 1021 & John Williams \\
1057 & Bill Witherspoon \\
2487 & Jennifer Twain \\
3769 & Sophia Lancaster \\
1017 & Debbie Reece \\
1275 & George McMullen \\
1899 & Ashley Smith \\
4218 & Josh Plemmons \\
\hline
\end{tabular}

Your program should allow the user to enter an ID number, then search the tree for the number. If the number is found, it should display the employee's name. If the node is not found, it should display a message indicating so.

Commonly Used Operators
Assignment Operators
= Assignment
\(+=\quad\) Combined addition/assignment
-= Combined subtraction/assignment
*= Combined multiplication/assignment
\(I=\quad\) Combined division/assignment
\(\%=\quad\) Combined modulus/assignment
Arithmetic Operators
\begin{tabular}{ll}
+ & Addition \\
* & Subtraction \\
\hline
\end{tabular}
* Multiplication
/ Division
\% Modulus (remainder)
Relational Operators
\(<\quad\) Less than
<= Less than or equal to
\(>\quad\) Greater than
>= Greater than or equal to
== Equal to
!= Not equal to
Logical Operators
\&\& \(\begin{array}{ll}\text { AND } \\ |\mid & \text { OR }\end{array}\)
! NOT
Increment/Decrement
++ Increment
-- Decrement
```

Conditional Operator? :
Form:
expression ? expression : expression
Example:
$\mathrm{x}=\mathrm{a}<\mathrm{b}$ ? a : b;
The statement above works like:
if ( $\mathrm{a}<\mathrm{b}$ )
$x=a ;$
else
$\mathrm{x}=\mathrm{b}$;

```
```

The while Loop
Form: Example:
while (expression) while (x < 100)
statement; cout << x++ << end1;
while (expression) while (x < 100)
{ {
statement; cout << x << end1;
statement; x++;
} }

```

The do-while Loop

Form:
do
statement;
while (expression);
do
    statement;
    statement;
\} while (expression); \} while (x < 100);

\section*{C++ Quick Reference (continued)}
```

The for Loop
Form:
for (initialization; test; update)
statement:
for (initialization; test; update)
{
statement;
statement;
}

```

\section*{Example:}
```

The switch/case Construct
The switch/case Construct

```
```

Form:

```
Form:
switch (integer-expression)
switch (integer-expression)
{
{
    case integer-constant:
    case integer-constant:
    statement(s);
    statement(s);
    break;
    break;
    case integer-constant:
    case integer-constant:
    statement(s);
    statement(s);
    break;
    break;
    default:
    default:
        statement;
        statement;
}
}
```

    break,
    ```
```

    break,
    ```
```

Example:
switch (choice)
{
case 0 :
cout << "You selected 0.\n";
break;
case 1 :
cout << "You selected 1.\n";
break;
default :
cout << "You did not select 0 or 1.\n";
}

```

\section*{Using cout}

Requires <iostream> header file.
\begin{tabular}{ll} 
Commonly used stream manipulators \\
Name \\
end1 & \begin{tabular}{l} 
Description \\
Advances output to the beginning \\
of the next line
\end{tabular} \\
fixed & \begin{tabular}{l} 
Sets fixed point notation
\end{tabular} \\
1 eft & \begin{tabular}{l} 
Sets left justification \\
right
\end{tabular} \\
setprecision & \begin{tabular}{l} 
Sets right justification \\
Sets the number of significant \\
digits
\end{tabular} \\
setw & \begin{tabular}{l} 
Sets field width
\end{tabular} \\
showpoint & \begin{tabular}{l} 
Forces decimal point \(\&\) trailing \\
zeros to display
\end{tabular}
\end{tabular}

\section*{Example:}
cout << setprecision(2) << fixed
<< left << x << endl;
Member functions for output formatting
Name Description
precision Sets the number of significant digits
setf Sets one or more ios flags
unsetf Clears one or more ios flags
width Sets field width
Example:
cout.precision(2);
```

for (count = 0; count < 10; count++)
cout << count << end1;
for (count = 0; count < 10; count++)
{
cout << "The value of count is ";
cout << count << end1;
}

```
\begin{tabular}{ll} 
Using cin & \\
Requires <iostream> header file \\
Commonly used stream manipulators \\
Name & Description \\
setw & Sets field width \\
Member & functions for specialized input \\
Name & Description \\
getline & Reads a line input as a C-string \\
get & Reads a character \\
ignore & Ignores the last character entered \\
width & Sets field width
\end{tabular}

\section*{Some Commonly Used Library Functions}

Name Description
(The following require <string>)
stod Converts a string to a double
stoi Converts a string to an int
stol Converts a string to a long int
(The following require <cstdlib>)
rand Generates a pseudo-random number srand \(\quad\) Sets seed value for random numbers (The following require <cctype>)
islower Returns true if char argument is lowercase
isupper Returns true if char argument is uppercase
tolower Returns the lowercase equivalent of the char argument
toupper Returns the uppercase equivalent of the char argument
(The following require <cmath>)
pow Raises a number to a power
sqrt Returns square root of a number
(The following require <cstring>)
strcat Appends a C-string to another C-string
strcpy Copies a C-string
strlen Returns the length of a C-string

value-returning functions, 362-370
calling, 364-370
defining, 362-363
variable declaration, 49
variable definitions, 49, 70
variables, 48-49
control, 271
flag, 215-216
global, 374-376
instance, 849-856
integer, 76, 216
local, 372-374, 379-380, 380-383
loop control, 271
names, 75
overflow and underflow, 134-135
with same name, 247-248, 379-380
static member, 850-856
structure, 649-650, 653
capacity member function, 480
clear member function, 477,480
compared to linked list, 1155
defining, 468-469
empty member function, 478-479, 480
initialization list, with C++ 11, 469
at member function, 480
pop_back member function, 480
push_back member function, 473-474, 480
range-based for loop, 471-473
removing elements from, 476-477
resize member function, 481
reverse member function, 480
searching and sorting, 527-529
size member function, 475-476
STL, 467-468
storing and retrieving values in, 469-471
swap member function, 481
vector, 1072
basic operations, 1075-1076
capacity () member function, 1084-1085
defining, 1075-1076
definition statements, 1072-1073
emplace() member function, 1082-1084
emplace_back() member function, 1082-1084
insert member function, 1077-1079
iterators usage, 1077
max_size() member function, 1084-1085
member functions, 1073-1075
reserve() member function, 1084-1085
shrink_to_fit() member function, 1084-1085
storing values in, 1080-1082
virtual destructors, 979-995, 990-995
virtual functions
and polymorphism, 985-987
pure, 995-999
virtual key word, 981
virtual member functions, 979-995
Visual Basic, 43
void function, 339
volatile memory, RAM as, 37

\section*{W}
weak_ptr, 573
Web browsers, 301
while loops, 268-274, 297
input validation with, 275-277
logic of, 269-271
as pretest loop, 271
programming style, 273-274
whitespace characters, 152
whole-part relationship, 900
word processors, 301, 697
write member function, file stream objects, 721

\section*{Z}
zero(s)
division by, 201, 1021-1022
trailing, 149, 150

\section*{GLOBAL EDITION}

For these Global Editions, the editorial team at Pearson has collaborated with educators across the world to address a wide range of subjects and requirements, equipping students with the best possible learning tools. This Global Edition preserves the cutting-edge approach and pedagogy of the original, but also features alterations, customization, and adaptation from the North American version.

> This is a special edition of an established title widely used by colleges and universities throughout the world. Pearson published this exclusive edition for the benefit of students outside the United States and Canada. If you purchased this book within the United States or Canada, you should be aware that it has been imported without the approval of the Publisher or Author.

Pearson Global Edition```

[^0]:    *Some compilers use 10 bytes for 1 ong doubles. This allows a range of $\pm 3.4 \mathrm{E}-4932$ to $\pm 1.1 \mathrm{E} 4832$.

[^1]:    *The assignment operator works from right to left. 12 is first assigned to $d$, then to $c$, then to $b$, then to a.

[^2]:    For count is set to the values 0 through the number of donations Set arrPtr[count] to the address of donations[count].
    End For
    Call arrSelectSort
    Call showArrPtr
    Call showArray

[^3]:    * These functions actually return an int value. The return value is nonzero to indicate true, or zero to indicate false.

[^4]:    *Because inline functions cause code to increase in size, they can decrease performance on systems that use paging.
    ${ }^{\dagger}$ Writing a function inline is a request to the compiler. The compiler will ignore the request if inline expansion is not possible or practical.

[^5]:    ${ }^{1}$ The $\mathrm{C}++17$ standard will introduce a sixth category, the contiguous iterator. A contiguous iterator is a random-access iterator that points to elements known to be stored in contiguous memory locations.
