

Lecture 1

MATERIALS USED IN ELECTRONICS

INSULATORS, CONDUCTORS, AND SEMICONDUCTORS

DR. BASSAM ATIEH

Insulators: An insulator is a material that does not conduct electrical current under normal conditions. Most good insulators are compounds rather than single-element materials and have very high resistivity's. Valence electrons are tightly bound to the atoms; therefore, there are very few free electrons in an insulator.

Examples of insulators are rubber, plastics, glass, mica, and quartz.

Conductors: A conductor is a material that easily conducts electrical current. Most metals are good conductors. The best conductors are single-element materials, such as copper (Cu), silver (Ag), gold (Au), and aluminum (Al), which are characterized by atoms with only one valence electron very loosely bound to the atom. These loosely bound valence electrons become free electrons. in a conductive material the free electrons are valence electrons.

Semiconductors:

A semiconductor is a material that is **between conductors and insulators** in its ability to conduct electrical current.

- A semiconductor in its pure (intrinsic) state is neither a good conductor nor a good insulator.
- **Single-element semiconductors are antimony (Sb), arsenic (As), astatine (At), boron (B), polonium (Po), tellurium (Te), silicon (Si), and germanium (Ge).**
- **The single-element semiconductors are characterized by atoms with four valence electrons. Silicon is the most commonly used semiconductor.**
- **Compound semiconductors such as gallium arsenide, indium phosphide, gallium nitride, silicon carbide, and silicon germanium are also commonly used.**

$$\rho = R \frac{A}{L} \text{ (Resistivity ohm}\cdot\text{cm)}$$

$$\sigma = \frac{1}{\rho} \text{ (Conductivity mho/cm)}$$

$$\text{mho} = \frac{1}{\text{ohm}} = \frac{1}{\Omega} = \mathcal{U}$$

BAND GAP

The difference in energy between the valence band and the conduction band is called an *energy gap* or band gap.

Energy

- Energy band diagram for an unexcited atom in a pure (intrinsic) silicon crystal.
- There are no electrons in the conduction band.

CONDUCTION ELECTRONS AND HOLES

Creation of electron-hole pairs in a silicon crystal. Electrons in the conduction band are free electrons.

ELECTRON AND HOLE CURRENT

جامعة
المنصورة

⑤ A valence electron moves into 4th hole and leaves a 5th hole.

③ A valence electron moves into 2nd hole and leaves a 3rd hole.

① A free electron leaves hole in valence shell.

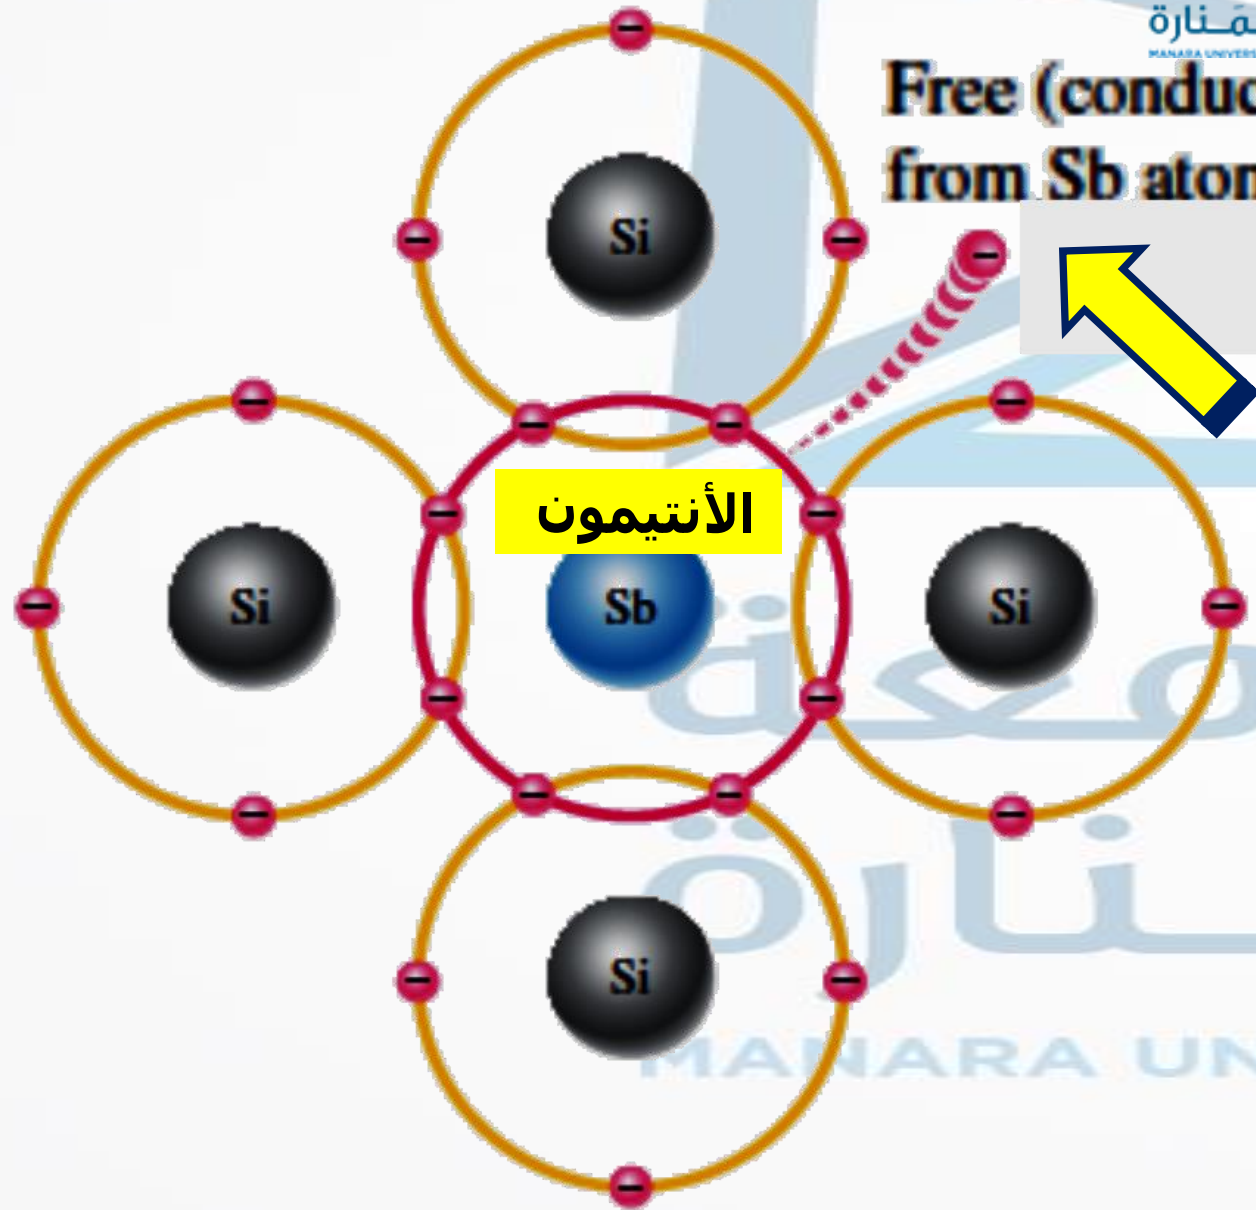

⑥ A valence electron moves into 5th hole and leaves a 6th hole.

④ A valence electron moves into 3rd hole and leaves a 4th hole.

② A valence electron moves into 1st hole and leaves a 2nd hole.

N-TYPE SEMICONDUCTOR

Free (conduction) electron
from Sb atom

Pentavalent impurity atom in a silicon crystal structure. An antimony (Sb) impurity atom is shown in the center. The extra electron from the Sb atom becomes a free electron.

P-TYPE SEMICONDUCTOR

**Trivalent impurity atom
in a silicon crystal
structure.**

**A boron (B) impurity
atom is shown in the
center.**
